THREE of the Four Divisions of the ENGLISH CYCLOPÆDIA having been completed, and the publication of the FOURTH DIVISION having commenced, the Proprietors desire to call attention to the character of the Cyclopædia, as a *complete* body of knowledge.

As separate works, the nature of the Cyclopædia of GEOGRAPHY, of BIOGRAPHY, of NATURAL HISTORY, and of ARTS AND SCIENCES, is sufficiently clear. But, taken as a whole, the connection of these great Divisions may require some very brief elucidation.

If the English Cyclopædia had been arranged in *two* Alphabets instead of in four, the one department might have been called *Literary*, the other *Scientific*.

The Cyclopædia of GEOGRAPHY, and the Cyclopædia of BIOGRAPHY, forming Ten Volumes, embrace together not only the Description of every Country, but its History in all ages. Under the Geographical name will be found a rapid view of a nation's progress. Under the Biographical names will be found all the great public events, and the religious, moral, and intellectual history of every State, as detailed in the lives of its eminent citizens.

The Cyclopædia of NATURAL HISTORY, and the Cyclopædia of ARTS AND SCIENCES, now in course of publication, and forming also Ten Volumes, present every feature of the Physical and Moral Sciences, and of the applications of Science to Productive Industry. This concluding Division also embraces all branches of miscellaneous information not strictly referable to these general heads.

The English Cyclopædia is founded upon the valuable Copyright of the Penny Cyclopædia, which has always remained in the hands of MR. KNIGHT. Every article in that celebrated work was an original contribution, furnished by many of the most eminent men of the time. The elaborate revisions, with the large additions, of the present work, have involved a new outlay for literary labour of not less than Seven Thousand Pounds, making the cost of literary production alone of these Twenty Volumes, not far short of Fifty Thousand Pounds.

THE

ENGLISH CYCLOPÆDIA.

A New Dictionary of Universal Knowledge.

CONDUCTED BY CHARLES KNIGHT.

ARTS AND SCIENCES.—VOLUME I.

LONDON:
BRADBURY AND EVANS, 11, BOUVERIE STREET.
1859.

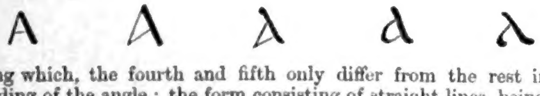
BRADBURY AND EVANS, PRINTERS, WHITEFRIARS.

THE

ENGLISH CYCLOPÆDIA.

ARTS AND SCIENCES.

A, the first letter of the alphabet in the English, and many other languages. As a sound, its power in the English language is at least fourfold, as in the words *father*, *call*, *tame*, and *hat*. The first of these sounds is that which generally prevails in other languages. The modified pronunciation of the vowel in *tame* is partly due to the vowel *e* at the end of the word; in *call* and similar forms, the peculiarity arises from the letter *l*; so that the only true sounds of the vowel are perhaps the long sound in *father*, and the short one in *hat*. The printed forms of this letter, viz., the capital A, the small character a, and the italic *a*, are all derived from a common form, differing but slightly from the first of the three. In the old Greek and Latin alphabets, from which our own has descended, the following were the ordinary figures of this letter:—



among which, the fourth and fifth only differ from the rest in the rounding of the angle; the form consisting of straight lines being well adapted for writing on stone, metal, &c.; the rounded letter, on the other hand, being better suited for expeditious writing, with softer or more flexible materials. From this last our two small characters are easily deduced. For the explanation of the fact that this letter is allowed the first place in the series of letters, see ALPHABET.

A or AN, the indefinite article. Of the two, *an* is used before a vowel. Where the following word begins with a consonant, it being more troublesome to express the final *n*, this letter, from not being pronounced ceased to be written. Thus we say *an emperor*, but instead of *an king*, we find it more convenient to say *a king*. Sometimes a virtual consonant exists at the beginning of a word without being written, as in *union* and *once*, where the ear catches the initial sounds of *y* and *w*, *younion* and *wunce*. Before such words it is customary to drop the final letter of the article, at least in pronunciation, and there can be no good reason for not writing *a union*, *a once beloved monarch*. On the other hand, whenever *h* is mute, we should retain the *n* both in writing and speaking, thus, *a history*, but *an historical work*. That *an* and not *a* is the primitive form of the article, is proved by the Anglo-Saxon *an*, and the German *ein*; indeed, our own numeral *one* is only another and fuller form of the same word. In such phrases as *three shillings a pound*, the article evidently has this meaning. The double shape of our article has led to a corrupt mode of writing certain words, thus from *an eft* was deduced *a neft*, *a newt*; and the reverse seems to have taken place in the change of *a nadder* to *an adder*.

A, as a prefix in English words. 1. In such words as *afoot*, *aside*, *aboard*, we have simply, as Horne Tooke observes, corrupted abbreviations of *on fote*, *on syde*, *on borde*, &c. This *on* is an Anglo-Saxon preposition with the meaning of *in*. Thus, in the old translation of the New Testament we have *he fell on sleep*, for *asleep*. The same is the origin of the *a*, which so often precedes our verbal nouns in *ing*, as *he is gone a-walking*, *the house was so many years a-building*; and indeed it was only by the suppression of this *a* that our imperfect participles in *ing* came into use. A similar formation appears in the French *en sortant*, &c., and the Celtic languages generally form their imperfect participle, by prefixing a preposition of similar power to the infinitive, that is, to an abstract noun expressing the idea of the verb. 2. But an *a* also appears at times in the formation of the perfect participle. Thus *ago*, formerly *agone*, *ashamed*, *afeard*, now dishonoured as a vulgarism, are the perfect participles of the verbs *go*, *shame*, and *fear*, the latter of which meant in our old writers, to cause, not to feel fear. It was only as a reflective verb *I fear me*, that we have the idea of the Latin *vereor*, and our modern *I fear*. This non-accented *a* is but a variety of the *y*, so familiar in the old participles *yclept*, *yseen*, &c., and consequently it represents the *ge* of the German *ge-gangen*, &c., which is commonly allowed to be an old preposition signifying *thoroughly*. 3. In some verbs of Saxon origin, the prefixed *a* represents the inseparable preposition *on* of the Anglo-Saxon, a little word no way connected with the preposition *on* already noticed, for it corresponds to the German *ent* and Greek *ανα*. Thus *to awake*, that is, *to wake up*, is the Anglo-Saxon *on-wacan*; and *a-cknowledge* is closely related to the Anglo-Saxon *on-cnáwan*, and the Latin *a-gnosc-ere*, whose prefix is of similar origin, and no way related to the ordinary Latin preposition *ad*. 4. On the other hand, in some of our Norman words, such as *amount*, *avail*, and their compounds, so familiar in legal language, *par-amount*, *par-aval* (See Mr. Ludlow's paper, 'Philolog. Soc. Trans.' for 1854, p. 114), we have, as in the ordinary French preposition *à*, the representative of the Latin *ad*, *ad montem, up*; *ad vallem, down*. 5. Lastly, our obsolete or Lowland-Scotch compound prepositions *a-fore*, *a-yont*, *a-hint*, must be placed beside the current forms, *be-fore*, *be-yond*, *be-hind*, *ab-aft*, *ab-out*, *ab-ove*; forms which point to a disyllabic preposition *abe*. In the same way, the Homeric *ενι*, appears in kindred languages sometimes as *in* or *en*, sometimes as *ni* or *ne*, and as *i* alone, as in *i' the*, &c.

AB, the fifth month of the ancient Hebrew year, but now the eleventh (or, in intercalary years, the twelfth), in consequence of the transfer of the new year from spring to autumn.

On the 1st day of Ab a fast is held in commemoration of the death of Aaron. On the 9th a fast is observed in remembrance of the destruction of the Holy Temple by Nebuchadnezzar in 588 B.C., and of the destruction of the second Temple by Titus, A.D. 70. This fast is considered the most mournful of the whole year. On the 18th another fast is observed. All these fasts are postponed one day if they fall on the Saturday.

A little festival called Tub-ab, or the fifteenth Ab, is celebrated on the 15th day, to commemorate an ancient custom, according to which the young girls of each tribe came forth into the fields clothed in white, and exhibited themselves in dances before the young men, with the view of being selected by them in marriage.

The month of Ab may begin in some years as early as the 10th of July, in others as late as the 7th of August.

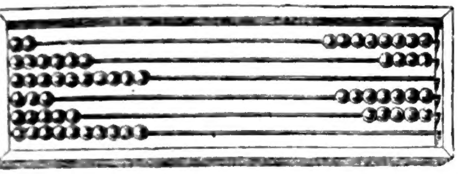
Ab is the name of the twelfth month of the Syrian year, coinciding with our August.

ABACISCUS, in architecture, is a diminution of the architectural term ABACUS, and is principally applied, when used at all, which is not often, to the tiles or squares of a tessellated pavement.

A'BACUS, a game among the Romans; so called from its being played on a board, somewhat in the manner of chess.

A'BACUS, in architecture, is the level tablet, whether square or oblong, which is almost always placed on the moulded or otherwise enriched capital of a column, to support the horizontal entablature. The architectural application of the term Abacus, which in the original is applied to any rectangular tile-like figure, arises from a story which Vitruvius tells of the manner in which the foliated capital called the Corinthian originated. The modifications in its form in the various orders of Greek and Roman architecture will be seen in the article COLUMN. In Gothic architecture, the abacus undergoes numerous changes and modifications, not merely in the several styles, but also in each style. To a great extent, it appears to have been treated in Gothic architecture according to the fancy of the individual architect: at any rate, it was not regulated by strict rules as in the classic orders. But it may be stated generally, that in the Romanesque, or what in England is commonly known as the Norman style, the abacus is usually square; in first pointed, or Early English gothic, it is nearly always round; and in the later styles more commonly octagonal. In French gothic however the square abacus was retained much longer than in the English.

ABACUS, an instrument employed to facilitate arithmetical calculations. The name may be given with propriety to any machine for reckoning with counters, beads, &c., in which one line is made to stand for units, another for tens, and so on. For teaching the first principles of arithmetic, a convenient abacus would be about three times as long as it is broad. It consists of a frame, traversed by stiff wires, on which beads or counters are strung so as to move easily. The beads on the first row are units, those on the next tens, and so on. There is an instrument sold in the toy-shops with twelve wires, and twelve beads on each wire, for teaching the multiplication-table; but it may be made still further useful in judicious hands.



The abacus can never be much used in this country, owing to our various division of weights and measures. We should need one abacus for pounds, shillings, and pence; another for avoirdupois weight; a third for troy weight; and so on. In China, however, where the whole system is decimal, that is, where every measure, weight, &c., is the tenth part of the next greater one, this instrument, called in Chinese shwanpan, is very much used, and with astonishing rapidity. It is said that while one man reads over rapidly a number of sums of money, another can add them so as to give the total as soon as the first has done reading. Their abacus differs from the one described above, in having only five beads on each wire, one of which is distinguished from the rest either in colour or size, and stands for five. There is one of these instruments in the East India Company's Museum. The Greeks and Romans used the same sort of abacus, at least in later times. The Russians are also much in the habit of performing calculations by strings of beads. A chequered board, such as we still sometimes see at the doors of public-houses, was formerly used in this country as an abacus, and a chess-board would now do very well for the purpose of instruction above-mentioned. The multiplication-table is sometimes called the Pythagorean abacus.

In 1839, Dr. Reid brought before the notice of the British Association a small apparatus, which he called a *Chemical Abacus*, and which he had found useful in introducing his pupils to a precise knowledge of the constitution of the more important chemical compounds. It consisted of a wooden frame with cross-wires and beads on the wires; each wire corresponded to a chemical element, and the beads to atoms; while the names of the elements were placed on the frame at the extremities of the wires. Dr. Daubeny suggested that the apparatus might be improved, by having the beads of different colours to correspond with the different elements.

The advocates of decimal coinage in England might strengthen their advocacy by a notice of the possible usefulness of the abacus as a reckoning apparatus under that system.

For mechanical aid of a more complex kind, in calculating and registering processes, see CALCULATING MACHINES. Examples of a special character are noticed under SLIDE RULE.

ABANDONMENT, a term used in marine insurances. Before a person, who insures a ship or goods, can demand from an insurer, or underwriter, the stipulated compensation for a total loss of such ship or goods, he must abandon or relinquish to the insurer, all his interest in any part of the property which may be saved.

ABATEMENT. This word is derived from the old French word *abater*, which signifies to beat down, prostrate, or destroy. But before entering upon an explanation of the present meaning of the term, it will be well to observe, for the information of those who may not be acquainted with the history of our law, that by far the greater number of the terms of art (as they may be called) peculiar to it, are derived either from the Norman-French, or the Latin. We shall therefore give a cursory view of the circumstances which led to their adoption.

When William I., commonly styled the Conqueror, became King of England, he filled all the posts of profit and honour with subjects from his Norman dominions—the civil places chiefly with ecclesiastics. Foreign priests having thus obtained all the seats of the judges and other officers of the superior courts of justice, it was found necessary to ordain that all proceedings in them should be carried on in the Norman tongue instead of the English, of which these new judges were for the most part altogether ignorant. This practice continued until Edward III. abolished the use of French, and substituted English as the language of such pleadings. At the same time that all arguments and judgments were spoken in French, the written parts of the proceedings, such as the writs and records, were engrossed in the Latin language, a practice which continued long after Edward III. had expelled the French tongue from our courts; for it was not until the reign of George II., that an Act of Parliament was passed, providing that writs and records should for the future be in English.

It will be evident that, under the circumstances described, the more ancient legal terms would, whenever that could conveniently be done, be translated into the French and Latin languages; and as, during the periods mentioned above, the laws of England experienced great alterations and received many additions, abundance of new terms were necessarily called for to express new notions, and were naturally drawn from the languages then in legal use. Many of the expressions thus translated, and those first invented, are employed at the present day with little or no alteration. Of this we have an example in the term which is the subject of this article.

The word *abatement* is used in its literal sense when we speak of abating or *beating down* a nuisance. Whatever unlawfully annoys or does damage to any person, is a nuisance, which he may abate, that is, beat down and remove: provided he commits no breach of the peace, and does no more injury to the thing than is necessary for effecting his purpose. If a new house or a wall be erected so near to an old house as to obstruct its ancient lights, this is a private nuisance, which the person injured may peaceably abate. If a gate or other obstruction be placed across a public road, this is a public nuisance, and any person may beat down and remove it. But a person thus taking the law into his own hands, must be careful, in every case, to do no more than is absolutely necessary to enable him to exercise or enjoy his own right.

Another signification of abatement is that of abating a civil action, or an indictment. Here it is taken figuratively, and signifies the beating down or overthrowing such action or indictment. This is effected in an action at law, by way of plea, stating some matter which renders it the duty of the court to put an end to the proceedings. Thus, it may be alleged that the plaintiff in such proceedings is an outlaw, or an attainted person, or otherwise incompetent to maintain an action; or that there are other persons still living who are equally liable with the defendant, and ought to be joined with him in the demand. But it is a rule that he who takes advantage of a flaw must, at the same time, show how it can be amended; and pleas in abatement must, therefore, not only point out the flaw, but disclose the remedy. Therefore, if a defendant pleads that another ought to be sued along with him, he must state where he can be found; for if he be not within the jurisdiction so as to be served with a writ, the plea is bad. Pleas in abatement have always been discouraged by the courts; and they are required to be verified by affidavit (4 & 5 Anne c. 16; 3 & 4 Will. IV. c. 45). But in consequence of the ample powers of amendment conferred by the Common Law Procedure Act, 1852, such pleas are now of rare occurrence.

A similar observation applies to pleas in abatement in criminal proceedings (14 & 15 Vict. c. 100). If an indictment assign to the defendant no Christian name or a wrong one, no surname or a wrong one, he may plead this matter in abatement; and so formerly, when an addition or description of the calling of a defendant was required, an error in or want of it was the subject of a plea. This addition or description is no longer necessary. (13 & 14 Vict. c. 100, s. 24.) Misnomer then is the only case in which a plea in abatement has been usual in practice; and, at the present day, such a plea is of no avail to a defendant, for the court has authority to amend the indictment, and then call upon the party to plead to the charge (Blackst. 'Comm.' Mr. Kerr's ed. vol. iii. p. 325; iv. 396). Again, if a plaintiff dies, or a female plaintiff marries, the proceedings are said to be abated; and if a defendant dies, the proceedings as to him are said to abate. Whenever the interest of the person who dies survives to those who represent him, the action or suit may be revived; and so when the subject matter of the proceeding is one for which the representatives of the deceased may be made liable, the action or suit may be revived and continued against them. ('Blackst. Comm.' Mr. Kerr's ed. vol. iii. pp. 463, 519.)

It is said to be "an abatement when a man dies seised of an estate of inheritance, and between the death and the entry of the heir, a stranger doth interpose himself and abate." ('Co. Litt.' 277 a.) This entry of a stranger on the lands is an abatement; the effect of which is that the true owner can only recover the seisin by entry [ENTRY]. If the abator died seised, the land descended to his heir, and the right of entry at common law was gone. The true owner must then have resorted to a particular form of action. Now, however, the right of entry subsists (3 & 4 Will. IV. c. 27), enabling the true owner to recover either by entry or the ordinary action of ejectment.

(Blackstone's *Commentaries*, Mr. Kerr's ed. vol. iii. p. 170.)

ABATEMENT OF LEGACIES. [LEGACY.]

ABATIS, a military term, signifying a work composed of felled trees, with the softer branches cut off, laid side by side with the ends from which the branches grow towards the enemy; thus forming an obstruction to his progress, and a breast-work for musketry to fire over. This species of defence is often used in fieldworks, where wood, not of too great size, is plentiful. Lines, flanked by bastions, are thus formed, either simply by laying down and fastening the trees, or, if when so placed they would be too high to fire over, by sinking them in a ditch whose section is an angle with its longest slope towards the enemy. They are sometimes formed against the counterscarp of a rampart, sometimes in the covered way, and may generally be used wherever an obstruction is to be raised to the enemy's progress, provided they can be flanked by a fire sufficient to prevent his destroying them at his leisure.

ABATTOIR. An abattoir is the French name for a slaughter-house. The existing French system was first adopted at Paris in 1817, and completed in 1818. There are three abattoirs on the north side of Paris, and two on the south side, not far from the barriers, and about two miles from the centre of the city. The cattle markets for the supply of Paris are several miles distant, and the cattle are driven from them round the exterior boulevards to the abattoirs, and consequently do not enter the city. At one of the abattoirs each butcher has his slaughter-house, a place for keeping the meat, an iron rack for fat, pans for melting it, and a place with convenience for giving cattle hay and water, and where they may be kept before being slaughtered. A fixed sum is charged for this accommodation, the charge for cattle being a franc and a half per head, and the blood, brains, and entrails. In some of the abattoirs, two or three butchers use the same slaughter-house. There are 240 slaughter-houses in all. The income of the establishment, arising from these fees, the sale of manure, &c., was above 48,000*l.* in 1842. An inspector is appointed at each abattoir, and means are taken to prevent unwholesome meat being sold. The manufactories of glue, gelatine, Prussian blue, hoof-oil, blood-manure, and other chemicals produced from offal, are conveniently placed near the abattoirs. Much of the fat is melted down at the abattoirs, and tripe is also prepared within the establishments. An excellent account of the abattoirs at Montmartre will be found in 'Household Words,' vol. ii. p. 556; and another in Head's 'Faggot of French Sticks.' There are slaughter-houses under public regulations in most of the Continental cities; and those of New York and Philadelphia, and some other of the cities of the American Union, are, it is said, placed on a similar footing.

The great cattle-market in Smithfield, for the supply of London, existed above five centuries, but the spot was originally a piece of waste ground beyond the city, instead of being, as at present, surrounded by a dense population. The cattle sold for the London market amount annually to about 240,000, the sheep to about 1,700,000, calves 28,000, and pigs 35,000. A large proportion of these are slaughtered within the limits of the metropolis. There are slaughtermen who kill for other butchers frequently above a hundred head of cattle, and perhaps five or six hundred sheep, every week; many butchers kill for themselves to a considerable extent, and there are few who have not accommodation for slaughtering and dressing a few sheep, either in the cellar underneath their shop, or in the rear of their premises. The slaughter-houses for sheep in Newgate Market, many of which are in cellars, and in Warwick Lane, are close to Newgate Street, and within a hundred and fifty yards of Ludgate Street, two of the great thoroughfares of London.

The inconveniences attending the system of having the cattle-market and the slaughter-houses in the midst of the metropolis were seriously felt; and, after a long opposition on the part of the city authorities, an Act of Parliament was passed in August 1851 for removing it to a spot of ground of about 15 acres, between the Caledonian Road and Maiden Lane, on the north of London. The execution was intrusted to the corporation of the city of London. It was undertaken and carried out in a liberal spirit. Considerable architectural merit is shown in the designs for the various buildings and the surrounding wall. Excellent accommodation has been provided for the animals, with a large supply of water for them and for cleansing the market, and facilities for the transaction of business, by the erection of banking-houses, hotels, &c. When completed, the old market in Smithfield was closed on September 11th, 1855, and the new one opened on September 13th. It provides space for about 35,000 sheep, 6600 oxen, 1425 calves, and 900 pigs; with lairage for 3000 oxen and 8000 sheep. There are two public slaughter-houses, at which 600 oxen can be killed weekly,—the only approach made in the metropolis to the abattoir system; but still the greater proportion of beasts and sheep are driven through the crowded streets of the metropolis to be killed at private slaughter-houses, many yet remaining in Warwick Lane and the vicinity of Newport Market. But strenuous attempts have been made to lessen the nuisance even in these. By the Towns Improvement Act (10 & 11 Vict. cap. 34, 1857), they have to be registered and licensed; even for those in which private butchers slaughter at home powers of inspection are given, and provision is made for the removal of offal and ordure. These regulations are not confined to the metropolis, but are extended to all towns; and the execution of the provisions of the Act were intrusted to Boards of Health, and are now, by the Local Government Act (21 & 22 Vict. cap. 98), transferred to the municipality or other governing body of the town or place; but as the adoption of this Act is optional, the supervision in many places remains with the Boards of Health, or has not been brought into operation. These Acts are confined to England and Wales; but in Edinburgh an abattoir has been provided that may be a model to municipalities who may concern themselves for public good, and many other towns have provided themselves with excellent abattoirs within the last few years. In these places, however, the use of the abattoir is not compulsory and private slaughter-houses continue to exist in most if not in all of them.

ABBÉ is the French term for Abbot. In France, before the Revolution, Abbé was the denomination of a very numerous body of persons, who had little or no connection with the Church, except the apparent one which they derived from this title, which frequently occurs in the literary and political history of that period. Many of them had not even received the tonsure, which is, in Roman Catholic countries, the first and indispensable mark of the clerical character. So far back as the end of the 17th century, we find Richelet, the lexicographer, complaining that there was scarcely a young man, tolerably well made, and who had acquired the air of an ecclesiastic, who did not, by an insufferable abuse, assume the style of Monsieur l'Abbé. Another author, Mercier, writing a century later, describes, with some asperity, the effeminate manners and dandyism of the same class of characters. The abbés occupied a very conspicuous place in French society, and discharged a variety of domestic functions. Many of the abbés however followed a more useful and creditable way of life. Some acted as private tutors in families, though these were seldom treated with much respect, and were consequently in general persons of very inferior qualifications. Others were professors of the university; and a great many employed themselves as men of letters, in which capacity their labours have given to the title of Abbé an honourable celebrity, and redeemed it from the universal contempt to which swarms of frivolous and intriguing sycophants would otherwise have reduced it.

ABBÉS COMMENDATAIRES, were such abbés as held abbeys in commendam,—that is, with the right of administering their revenues, or a part of them. There were, before the Revolution, between 200 and 300 abbeys in France, which the king had the privilege of conferring in commendam; and it was the expectation of obtaining one of these benefices which induced so many persons to take the title of Abbé. Before obtaining such preferment, they used to be called *Abbés de sainte espérance*, abbés of holy hope. After they were thus provided for, they were Abbés Commendataires. The papal bull, which ratified their appointment, commanded them in all cases to get themselves ordained priests within the year, or as soon as they should arrive at the canonical age (five-and-twenty) on pain of the benefice being declared vacant; but it was common to obtain dispensations for disregarding this condition, and most of them remained Secular Abbés. The Abbé Commendataire received the third part of the revenues of his abbey, and also enjoyed certain dignities and privileges which it is unnecessary to specify; but the actual government of the house was committed to the hands of a resident superior, the *prieur claustral,* who was in almost all respects quite independent of the sinecurist, his colleague.

ABBESS, the superior of a nunnery, or other female religious community. An abbess, in the Roman Catholic Church, possesses, in general, the same dignity and authority as an abbot, except that she cannot exercise the spiritual functions appertaining to the priesthood. According to a decree of the Council of Trent, an abbess, at the time of her election, ought to be at least forty years old, and to have made profession for eight years. It is forbidden that any person be elected to the dignity who has not been professed for five years, or is under thirty years of age.

ABBEY, a religious community presided over by an abbot or abbess. When the superior was denominated a prior, the establishment was called a priory; but there was latterly no real distinction between a priory and an abbey. The priories appear to have been all originally off-shoots from certain abbeys, to which they continued for some time to be regarded as subordinate. The wealthiest abbeys, in former times, were in Germany; and of all such foundations in the world, the most splendid and powerful was that of Fulda, or Fulden, situated near the town of the same name in Franconia. This monastery, which belonged to the order of St Benedict, was founded by St. Boniface, in the year 784. Every candidate for admission was required to prove his nobility. The monks elected their abbot from their own number; and that dignitary became, by right of his office, Arch-Chancellor to the Empress, and Prince Bishop of the diocese of Fulda. He claimed precedence over all the other abbots both of Germany and of France. One of the first effects of the Reformation both in England and in Germany was the destruction of the religious houses; although, even in the Protestant parts of the latter country, a few male and female monastic communities still subsist. In England their extinction was complete. The preface to Bishop Tanner's 'Notitia Monastica' may be consulted for the most accurate account that has been given of the number and revenues of the English monasteries at the time of the dissolution. From this statement, it appears that, by the Act of Parliament passed in 1535 for the suppression of all those having a less revenue than 200*l.* a-year, about 380 houses were dissolved; from whose possessions the crown derived a revenue of 32,000*l.*, besides plate and jewels to the value of about 100,000*l.* By an act passed in 1539, all the remaining monasteries were suppressed, to the number of 186; the revenues of these amounted to 100,000*l.* per annum. Besides the monasteries, 48 houses of the knights hospitallers of St. John were also confiscated to the crown. Other authorities make the wealth of the monastic establishments much greater than it would appear to have been from this account; and it is probable that the revenues of many of them, at the period of the dissolution, had been considerably diminished by the precautions which the abbots were led to take in anticipation of that event. Camden states the whole number of the religious houses that were suppressed at 645. In the earlier times of the French monarchy, the term abbey was applied to a duchy or earldom, as well as to a religious establishment; and the dukes and counts called themselves abbots, although remaining in all respects secular persons. They took this title in consequence of the possessions of certain abbeys having been conferred upon them by the crown.

ABBOT, the title of the superior of certain establishments of religious persons of the male sex, thence called Abbeys. The word *Abbot*, or *Abbat*, as it has been sometimes written, comes from *Abbatis*, the genitive of *Abbas*, which is the Greek and Latin form of the Syriac *Abba*, of which the original is the Hebrew *Ab*, father. It is, therefore, merely an epithet of respect and reverence, and appears to have been at first applied to any member of the clerical order, just as the French Père and the English Father, having the same signification, still are in the Catholic Church. In the earliest age of monastic institutions, however, the monks were not even priests; they were merely religious persons who retired from the world to live in common, and the abbot was that one of their number whom they chose to preside over the association. In regard to general ecclesiastical discipline, all these communities were at this time subject to the bishop of the diocese, and even to the pastor of the parochial district within the bounds of which they were established. At length it began to be usual for the Abbot, or, as he was called in the Greek Church, the Archimandrite, or Hegumenos (that is, the chief monk, or leader), to be in orders; and since the 6th century monks generally have been priests. In point of dignity an abbot is next to a bishop; but there have been many abbots in different countries who have claimed almost an equality in rank with the episcopal order. A minute account of the different descriptions of abbots may be found in Du Cange's 'Glossary,' and in Carpentier's Supplement to that work. In England, according to Coke, there used to be twenty-six abbots (Fuller says twenty-seven), and two priors who were Lords of Parliament. These, sometimes designated Sovereigns, or General Abbots, wore a mitre, not exactly the same as that of the bishops, carried the crozier in their right hand, while the bishops carried theirs in their left, and assumed the episcopal style of Lord. Some croziered abbots, again, were not mitred, and others who were mitred were not croziered. Abbots who presided over establishments that had sent out several branches were styled Cardinal-Abbots. There were likewise, in Germany, Prince-Abbots, as well as Prince-Bishops. In early times we read of Field-Abbots (in Latin, *Abbates Milites*) and Abbot-Counts (*Abba-Comites*, or *Abbi-Comites*). These were secular persons, upon whom the sovereign had bestowed certain abbeys, for which they were obliged to render military service as for common fiefs. A remnant of this practice appears to have subsisted in our own country long after it had been discontinued on the Continent. Thus, in Scotland, James Stuart, the natural son of James V., more celebrated as the Regent Murray, was, at the time of the Reformation, Prior of St. Andrew's, although a secular person. The secularisation of some of the German ecclesiastic dignities has since occasioned something like a renewal of the ancient usage. We have in the present century seen a prince of the House of Brunswick (the late Duke of York) at the same time Commander-in-Chief of the British army and Bishop of Osnaburg.

The efforts of the abbots to throw off the authority of their diocesans long disturbed the Church, and called forth severe denunciations from several of the early councils. Some abbeys, however, obtained special charters recognising their independence; a boon which, although acquired at first with the consent of the bishop, was usually defended against his successors with the most jealous punctiliousness. Many of the abbots lived in the enjoyment of great power and state. In ancient times they possessed nearly absolute authority in their monasteries. The external pomp and splendour with which an abbot was in many cases surrounded, corresponded to the extensive authority which he enjoyed within his abbey, and throughout its domains. St. Bernard is thought to refer to the celebrated Luger, abbot of St. Denis, in the beginning of the 12th century, when he speaks, in one of his writings, of having seen an abbot at the head of more than 600 horsemen, who served him as a cortège. Even in the unreformed parts of the Continent, however, and long before the French Revolution, the powers of the heads of monasteries, as well as those of other ecclesiastical persons, had been reduced to comparatively narrow limits; and the sovereignty both of abbots and bishops had been subjected in all material points to the authority of the civil magistrate.

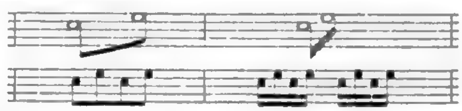
The title of Abbot has also been borne by the civil authorities in some places, especially among the Genoese, one of whose chief magistrates used to be called the Abbot of the People. Nor must we forget another application of the term which was once famous in our own and other countries. In many of the French towns there used, of old, to be annually elected from among the burgesses, by the magistrates, an Abbé de Liesse (in Latin *Abbas Lætitiæ*), that is, an Abbot of Joy, who acted for the year as a sort of master of the revels, presiding over and directing all their public shows. Among the retainers of some great families in England was an officer of a similar description, styled the Abbot of Misrule; and in Scotland the Abbot of Unreason was, before the Reformation, a personage who acted a principal part in the diversions of the populace, and one of those whom the zeal of the reforming divines was most eager in proscribing.

ABBREVIATION, a mathematical term, given to the process by which a fraction is reduced to lower terms. Thus, the division of the numerator and denominator of $\frac{48}{56}$ by 8, which reduces it to $\frac{6}{7}$, abbreviates the fraction.

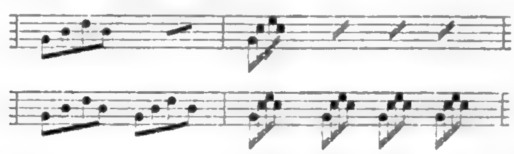
ABBREVIATION, in music, is a kind of stenography, or shorthand, which much diminishes the labour of the composer and copyist. It frequently happens, not only that the same note is reiterated, but that the same passage is repeated; and the necessity of writing at length such repetitions is avoided by the use of certain well-contrived and simple abbreviations. Those most commonly employed are:—I. One dash or more, through the stem of a minim or crochet, or under a semibreve, by which such note is converted into as many quavers, semiquavers, &c., as it is equal to in time. Ex.

are to be played thus,—

II. Two alternate notes, frequently repeated, are commonly abridged in the following manner,—



III. The groups of notes called arpeggios are thus contracted, the dash alone denoting repetition;—



IV. The word *simili* (the same) signifies that the group of notes is to be repeated. *Bis* (twice) written over a bar, or a passage, denotes repetition.

ABBREVIATIONS, the shortening of a word or phrase, made either by omitting some letters or words, or by substituting some arbitrary mark.

Abbreviations are of two kinds; first, those which are used in familiar speech, by which two words are made one, as can't for can not, won't for will not, &c., and those which are employed in writing only; our business is with the latter.

Before the invention of printing, every expedient to abridge the enormous labour of copying would be naturally adopted, and the principle, once introduced, was followed where the necessity which led to its first employment no longer existed. Latin inscriptions are not unfrequently quite unintelligible to the best scholar who has not given the subject his particular attention, and many are ambiguous even to the most skilful. The most usual Latin abbreviation is the initial letter instead of the whole word; whether a name, as M. for Marcus, P. for Publius; or a relation, as F. for filius, a son; or an officer, as C. for consul, Qu. for quæstor, &c.

The Rabbins carried this practice to a great extent; and although, in copying the Bible, they carefully abstained from abbreviations, their other writings are filled with them. They even carried their abbreviations into their common tongue, and when they had contracted a name or sentence, by taking the initials only, they made words of the unconnected letters by the interposition of vowels. Thus, for Rabbi Levi ben Gerson, they took the first letters, R.L.B.G.; and, by the interposition of vowels, made the word Ralbag.

In the middle ages the practice of abbreviating increased; and even in printing, where the employment of contractions was much less necessary, the old mode was by no means abandoned. Many writings became unintelligible; and in matters of law and government the difficulties thus created demanded the interposition of Government. An Act of Parliament was passed in the fourth year of George II., by which the use of abbreviations was altogether forbidden in legal documents; and although this was so far modified by another act, within a year or two, allowing the use of those of common occurrence, the old practice was never completely revived. A few only are still employed, chiefly in titles, coins, and commercial transactions; the most important of which follow:

ABDICATION (from the Latin *abdicatio*) is the act of renouncing and giving up an office by the voluntary act of the party who holds it. But the term is now applied to the giving up of the regal office; and in some countries a king can abdicate in the proper sense of that term, whenever he pleases. But the Sovereign of England cannot abdicate, except with the consent of the two Houses of Parliament, in any constitutional form; for a proper abdication would be a divesting himself of his regal powers by his own will, and such an abdication is inconsistent with the nature of his kingly office. It is, however, established by a precedent that he does abdicate, or that an abdication may be presumed, if he does acts which are inconsistent with and subversive of that system of government of which he forms a part. Thus it was resolved by both Houses, in 1688, "King James II. having endeavoured to subvert the constitution of the kingdom, by breaking the original contract between king and people; and by the advice of Jesuits and other wicked persons, having violated the fundamental laws, and having withdrawn himself out of the kingdom; has abdicated the government, and the throne is thereby vacant." The Houses, in this well-known instance, proceeded on the doctrine of an *original contract* between the king and the people, as the foundation of their declaration that James II. had abdicated the throne; and hence, Blackstone, in arguing upon this declaration, assumes that the powers of the King of England were originally delegated to him by the nation. ('Blackstone's Commentaries,' Mr. Kerr's ed., vol. i., p. 198.)

It appears, by the parliamentary debates at that period, that in the conference between the two Houses of Parliament, previous to the passing of the statute which settled the crown upon William III., it was disputed whether the word "abdicated," or "deserted," should be the term used, to denote in the Journals the conduct of James II. in quitting the country. It was then resolved that the word "abdicate" should be used, as including in it the mal-administration of his government. It has been said that, in coming to this resolution, the Houses gave a new meaning to the word.

Among the Romans the term *Abdicatio* signified generally a rejection or giving up of a thing, and a magistrate was said to abdicate who for any reason gave up his office before the term was expired.

ABDOMEN, DISEASES OF. The abdomen is one of the largest cavities of the body, and besides the peritoneum, with which it is everywhere lined, contains the greater part of the digestive organs, the urinary organs, and the internal organs of generation. [ABDOMEN, NAT. HIST. DIV.] Any one of these organs may become diseased, and as they are all more or less accessible by external examination, it is of great importance in cases of suspected abdominal disease, that this should be had recourse to.

There is no part of the human body so well adapted for this kind of examination as the abdomen. Its walls are soft and yielding; some of its most important organs lie immediately beneath the surface; though they cannot be seen they can be felt; and several of their morbid conditions can therefore be ascertained with clearness and certainty.

Not only are some of the diseases of the abdominal viscera visible to the naked eye, but they are even strikingly expressed; for they either cause a permanent change in the configuration of the abdomen, or they produce a temporary alteration of its natural movements, or they occasion both effects.

Both in the male and in the female it often happens that diseases not to be ascertained, or at any rate exceedingly apt to be overlooked, or mistaken, if the region of the part affected be covered with its ordinary clothing, become manifest the moment the part in question is uncovered; or if not, are rendered obvious by other modes of inspection to which the removal of the clothing is indispensable.

The external examination of the abdomen, or the exploration of it, as it is technically termed, is comprised in simple inspection, manual examination, and percussion.

1. The simple inspection of the abdomen often affords valuable information. The mere alteration of its form is sometimes of itself sufficient to determine the seat and the nature of the disease. In each case of diseased organs the change is different; in each it is peculiar, and even characteristic. The abdomen may be affected with spasm, as in the disease called colic, or with inflammation, as in the disease called enteritis. Life may depend on the promptitude with which the true nature of the affection is detected. One set of remedies is required for one of these diseases, and a totally different set for the other. Remedies essential to the preservation of life, if the disease be inflammation, may be destructive of life, if the disease be merely spasm; and if under the notion that the disease is spasm, the remedies proper for inflammation be not employed, death may be the consequence of the error in less than twenty-four hours. In both affections the pain may be the same, and several other symptoms may be similar, but the form of the abdomen may be alone sufficient to determine the true nature of the malady; for, if it be inflammation, the abdomen will be rounded, enlarged, and distended; while if it be spasm, it will be drawn in and contracted. There are affections which place life in the most imminent danger, especially in children, in which it is difficult, if not impossible, to determine, from the symptoms alone, whether the seat of the disease be in the brain, or in the inner coat of the intestines. Suppose it be in the brain, one set of remedies are required, which must be applied to the head; suppose it be in the intestines, a different sort of remedies is required, which must be applied to the belly. An index is sometimes afforded to the real seat of the disease, by the mere form of the abdomen; while its size, combined with its form, oftener affords a still more certain guide; and so does any deviation from its natural movements.

2. Manual examination affords still more correct and complete information relative to the condition of the abdominal organs. The size, the tension, the temperature, the sensibility of the abdomen, the presence or absence of unnatural tumours or morbid growths within its cavity, the presence or absence of fluids, the nature and extent of the contents of the intestinal canal, may be ascertained with considerable precision by touch combined with pressure. Increase of temperature on the surface of the body is a most important sign of internal disease. Increase of temperature arises from a preternatural increase in the action of the arteries, and denotes inflammation of the part affected. All acutely inflamed organs are hotter than in their natural state, and if the inflammation be intense, the neighbourhood of the inflamed part gives to the hand of the examiner the sensation of pungent heat,

which is always a sign not only of disease, but of exceedingly severe disease.

Diminished temperature, which arises from diminished action in the arteries, and an overloaded state of the veins, is no less important as a sign of disease. It always denotes a most dangerous condition of the system, the danger being in proportion to the coldness. It is the concomitant of the worst forms of fever which are ever witnessed in this country; fever with a cold skin being incomparably more alarming than fever with even a pungently hot skin. In the cholera, the first, the most sure, and the most alarming sign of the invasion of the malady, is coldness of the system, and especially of the abdomen, the main seat of the malady; and it is uniformly found that there is no one sign which affords a better criterion of the extent of the danger, in any case, than the degree of coldness of the system in general, and of the abdomen in particular.

3. That mode of external examination of the body termed percussion —namely, the mode of eliciting sounds from the surface, the nature of the sound produced affording a knowledge of the condition of the parts beneath—has opened to the modern practitioner a new source of information, the careful and skilful employment of which has afforded practical results of far greater precision and importance than could possibly have been anticipated. This mode of examination has been applied principally, and with the most valuable results, to the detection of the diseases of the chest; but its application is just as necessary to diseases of the abdomen. The size of the liver, the part of the intestinal tube distended with air, and a variety of other particulars, may be obtained by the aid of percussion.

An account of the various diseases to which the abdominal viscera are subject, and their treatment, will be found in this work, either under the head of the diseases of the various organs, or the special terms by which such diseases are designated. [KIDNEYS, DISEASES OF; LIVER, DISEASES OF; ENTERITIS; PERITONITIS; DROPSY.]

ABDUCTION (from the Latin word *abductio*, which is from the verb *abducere*, to lead or carry off) is an unlawful taking away of the person of another, whether of child, wife, ward, heiress, or women generally.

Abduction of Child. [KIDNAPPING.]

Abduction of Wife may be either by open violence, or by fraud and persuasion. The law in both cases supposes force and constraint, the wife being unable to give a valid consent. The remedy of the husband in such a case is an action, by which he may recover, not the possession of his wife, but damages for taking her away; and by statute 3 Edward I. c. 13, the offender shall be imprisoned for two years, and fined at the pleasure of the king, that is, of the court. The husband is also entitled to recover damages against such as persuade and entice the wife to live separate from him without sufficient cause.

Abduction of Ward. A guardian is said to be entitled to an action if his ward be taken from him, but it is added that, for the damages recovered in such action, he must account to his ward when the ward comes of age. But it is very doubtful if such an action will now lie. It was grounded originally on the interest which the guardian, according to feudal notions, had in his ward's marriage; but since the abolition, in the reign of Charles II., of all the feudal tenures except socage, the ward's marriage has been of no value to the lord or guardian. An action would lie for loss of services, if the ward really rendered any to the guardian.

It may be added, that all questions between guardians and wards are now in general inquired into and determined by the Court of Chancery.

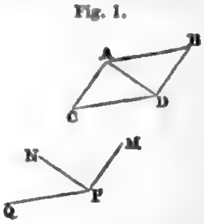
Abduction of Heiress. By 9 George IV. c. 31, when any woman shall have any interest in any estate real or personal, or shall be heiress presumptive or next of kin to any one having such interest, any person who from motives of lucre shall take or detain her against her will for the purpose of her being married or defiled, and all counsellors, aiders, and abettors of such offences are declared guilty of felony, and punishable by transportation for life, or not less than seven years, or imprisonment with or without hard labour. The taking of any unmarried girl under sixteen out of the possession of a parent or guardian is declared a misdemeanour, and is punishable by fine and imprisonment. The marriage, when obtained by means of force, may be set aside on that ground. In this case, as in many others, fraud is legally considered as equivalent to force; and, consequently, in a case where both the abduction and marriage were voluntary in fact, they were held in law to be forcible, the consent to both having been obtained by fraud.

Abduction of Women generally. The forcible abduction and marriage of women is a felony. Here, and in the case of stealing an heiress, the usual rule that a wife shall not give evidence for or against her husband is departed from, for in such case the woman can with no propriety be reckoned a wife where a main ingredient, her consent, was wanting to the contract of marriage; besides which, there is another rule of law, that "a man shall not take advantage of his own wrong," which would obviously be done here, if he who carries off a woman could, by forcibly marrying her, prevent her from being evidence against him, when she was perhaps the only witness to the fact.

ABERRATION (OF LIGHT), an astronomical phenomenon, being an apparent alteration in the place of a star, arising from the combined motion of the spectator, and the light which brings the impression of the star to his eye. We should however premise, in order that the reader may not form too large a notion of aberration, that it is never so much as 21", that is, the apparent place of the star differs from its real place less than the *ninetieth* part of the apparent diameter of the sun. It is no wonder, therefore, that practical astronomy was considerably advanced before this discovery was made. If our sense of vision were perfect, or if light moved no faster than a rain-drop we should have *terrestrial aberration*, that is, objects would change their relative places when we begin to move, and if we went as fast as a ray of light moved, the utmost confusion would be the consequence. When we ride in a carriage into which the rain is beating, we mistake the direction of the rain: for the cause of which phenomenon, see MOTION. But as light moves with a velocity which imagination cannot conceive, about 192,000 miles in a second, its motion is so great compared with any we can give to ourselves, that its passage from any one terrestrial object to another may be considered as instantaneous. The motion of a spectator on the earth, which goes round the sun at the average rate of about nineteen miles in one second, though less than the ten thousandth part of that of light, is nevertheless sufficient to cause a small variation in the place of the star, perceptible by the aid of good astronomical instruments.

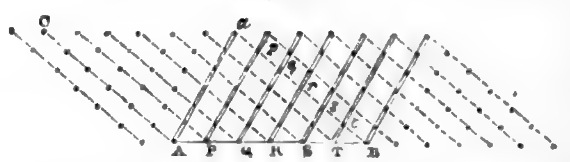
We know [MOTION] that if a body A be struck in two different directions at the same instant, with impulses which would separately carry it through AB and AC in one second of time, the result of the combined impulses is that it moves in one second through AD, the diagonal of the parallelogram, whose sides are AB, AC. Again, if the spectator and the object at which he is looking are both in motion, the appearances presented by the motion will be preserved, if we render the spectator stationary, provided we give to the object a velocity equal and contrary to that which the spectator *had*, in addition to its own. Hence, if the spectator move from P to Q in one second, while in the same time the object moves from A to C, and if AB be equal to PQ, the spectator, who does not perceive his own motion, will imagine that the object moves through AD in one second, he himself remaining at P. Hence, if rays of light move parallel to AC, and he can distinguish them, they will appear to him to move parallel to AD. Though he cannot see the light itself, he will mistake the direction of the object from which it comes; and if asked to point it out, will place his finger in the direction PN instead of PM. The following illustration will place this in a clearer light.

Fig. 1.



Let us suppose the rays to move so slowly, that a spectator can be furnished with a tube long enough for light to take some perceptible time in passing from one end of it to the other. This will do for our purpose, since, though by such a supposition the aberration will be very much increased, yet the effect, and the reason of it, will be of the same kind as if light were supposed to have its real velocity. The star being at an immense distance, the rays which reach the spectator in different parts of the second may be called parallel, without sensible error. Thus, while in one second the spectator moves from A to B, he receives rays of light in the direction indicated by the dotted lines. The question now is, in what direction must he hold the tube, so as to see the star through it? If he were at rest, that direction would evidently be AC.

Fig. 2.



Let AB be the line described by the spectator in one second, during which time let a ray of light move from a to B, or from C to A. Join Aa, and let Aa be the length and direction of the tube. Divide the second into any number of equal parts, say six, and carry the tube into the various positions which it will successively occupy. Consider a ray of light as a succession of little particles moving one after another in a straight line. Then when the eye has come to P, the particle a will have come to p; when the eye is at Q, the particle will be at q, and so on. We have then so placed the tube, that its motion will not interfere with that of the ray, which moves as freely in the moving tube as it would do if there were no tube. To the spectator, who does not perceive his own motion, the tube is stationary, and the ray of light appears to come down it; therefore Aa will be the direction in which he sees the star, instead of AC. The angle CAa, contained between the real and apparent directions, is what is called the *aberration*. Here aA is the diagonal of the parallelogram BaCA, in which aC is equal and opposite to AB, as before noticed. To apply this, we must remark,—

1. That the above figure is much distorted, since AB is not the ten thousandth of aB; whence the aberration will be very small.

2. That the aberration is in the plane passing through AB, the line of the earth's course for the moment, and through the real direction

A C of the star; whence, as the earth changes the direction of its motion in going round the sun, the direction of the aberration will also change.

3. That we have committed an error in supposing the lines A C and B a to be parallel, since they meet at the star; which error, on account of the star's enormous distance, will be imperceptible.

4. That A B is not properly the spectator's motion round the sun only, but compounded of that and his motion round the earth's axis; the latter, however, being at most not one-third of a mile in a second while the former is nineteen miles per second, the maximum effect of the diurnal aberration amounts to only a fraction of a second of space.

5. The real direction A C of the light may be considered as the same at every part of the earth's orbit, on account of the distance of the star.

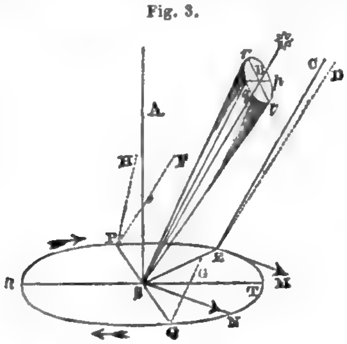
6. The aberration always throws the star apparently nearer to the earth's course, that is, A a is always within the angle C A B.

7. The aberration is greater or less according as the angle C A B is nearer to, or further from, a right angle, and is greatest when C A B is a right angle. This result may readily be proved by those who understand trigonometry, if they recollect that A B and a A are given, being the velocity of the earth and the *apparent* velocity of light, and that

$$\sin \mathrm{A}a\mathrm{B}, \text{ or } \sin \mathrm{CA}a = \frac{\mathrm{AB}}{a\mathrm{A}} \sin a\mathrm{BA} = \frac{\mathrm{AB}}{a\mathrm{A}} \sin \mathrm{CAB}.$$

Let us suppose, which will be exact enough for our purpose, that the earth moves in a circle (the ecliptic), of which the sun is in the centre. The line S A, perpendicular to the plane of the ecliptic, looks towards the *pole* of the ecliptic. Let S B be the direction of a star, P S Q perpendicular in the plane of the ecliptic to S B, and R S T perpendicular to P S Q in the same plane. When the earth is at E, it is moving in the direction E M, perpendicular to S E, and the star, from its great distance, is in the direction E C parallel to S B. Hence the aberration takes place in the plane C E M, that is, the star is a little lowered towards E M, and appears in the direction E D. Let the needle S N move round the circle with the earth, so as always to indicate the direction in which the earth is moving, that is, S N is always parallel to E M, and perpendicular to S E. The plane B S N being parallel to the plane C E M, is the plane in which aberration would appear to take place if the spectator were at S, and S was moving; but as the spectator does not perceive his own motion, let us suppose him placed at S, and the same aberration to take place in the plane B S N, which really does take place in C E M. By what has been said, the aberration is greatest when the needle points to Q or P, that is, when the earth is at T or R; and least, when the needle points to T or R, that is, when the earth is at P or Q; because the angle B S N is a right angle when N is at P or Q, and differs most from a right angle when N is at T or R. Hence the aberration increases as the earth moves from P to T, diminishes from T to Q, increases from Q to R, and decreases again from R to P. The line in which the star appears, moves round S B in the course of a year, and describes a cone, while the star appears to describe a small oval or ellipse about B, the greater axis of which is parallel to P Q, and the lesser to R T; such as $p\ r\ q\ t$, in which p is the apparent place when the earth is at P, and so on. This deviation is completed in the course of a year.

Fig. 3.



When the star itself is in the pole of the ecliptic, or is seen in the direction S A, the angle A S N, is always a right angle, the aberration is always of the same magnitude, and the apparent path of the star is a circle. As we take stars in which S B is more inclined to the ecliptic, the oval becomes flattened in proportion to its length, so that when the star is in the ecliptic, it appears to vibrate backwards and forwards in a straight line, going and returning once in each year.

If the star be on the solstitial colure, the points P and Q will be the equinoxes, and R and M the solstices. The aberration will consequently be greatest at the solstices, and least at the equinoxes. We shall refer to this case presently.

The stars appear to us to lie on a large sphere, of which we are at the centre. [SPHERE.] We may represent the phenomenon on a common globe, by drawing a small ellipse or oval round the star, the major axis of which is parallel to the ecliptic, and the figure of which is more or less flattened, as the star is nearer to, or further from, the ecliptic. The major axis will always be an arc of 41", and the minor axis will be 41" multiplied by the *sine* of B S M or the star's latitude.

Previously to entering upon the quantity of aberration, we shall give some account of the discovery, which is one of the most remarkable in the history of science. The arguments for the motion of the earth, though tolerably conclusive, were yet principally derived from the great simplicity of this hypothesis in comparison with others, since all the phenomena then observed could be equally well explained upon the supposition, that the other planets moved round the sun, at the same time that the sun moved round the earth. It remained, therefore, to find some *experimentum crucis*, some phenomenon, which admitted of no *other* explanation except what could be derived from the earth's motion. The first idea which suggested itself to astronomers was, that if the earth really moved, the stars would appear to change their places; though they did not count much upon this, since they knew that the distance of the stars might be so great, that the whole diameter of the earth's orbit would be too small a change of position to cause any perceptible change of place. [PARALLAX.]

However, the great improvements effected in practical astronomy towards the close of the 17th century, enabled astronomers to detect certain small changes in the apparent places of the stars, which had hitherto escaped observation, but which could not be satisfactorily explained by the parallax depending on the annual motion of the earth. Hooke, indeed, from observations of γ *Draconis*, made with a zenith sector of his own construction, was led to assign a parallax of sensible magnitude to that star, but the result at which he arrived was not generally admitted by astronomers. About the same time Picard remarked that the apparent place of the pole star was subject to a variation of which he could give no satisfactory account. Flamsteed, who independently detected the same phenomenon, attributed it to the effects of annual parallax, but Cassini showed that the direction in which the displacement occurred, was not in accordance with the effect which would result from the annual motion of the earth.* It may be mentioned also that Römer, a contemporary of Flamsteed, remarked certain changes in the declinations of the stars which, according to his pupil Horrebow ('Basis Astronomiæ,' p. 66) he was unable to explain either by parallax or refraction.

In the year 1725, Bradley, Savilian Professor of Astronomy at Oxford, and afterwards Astronomer Royal, and Molyneux, the son of Locke's well-known friend of that name, resolved to verify Hooke's observations of γ *Draconis*. This star had been selected by Hooke for his researches on annual parallax, because it passed very near the zenith of Gresham College, London, the place where his observations were made, and therefore would not be sensibly affected by refraction. The star manifestly offered the same facility of investigation to Bradley and Molyneux, whose observations were originally made at Kew. The instrument with which their observations were made was also a zenith sector, which, indeed, at that time was the most correct instrument for measuring very small angles [ZENITH SECTOR]; and a very large one, having a telescope 24 feet long, made by Graham, one of the most celebrated artists this country has produced, was erected at the place just mentioned, under the direction of Molyneux. Before proceeding further let us consider what would be the effect produced on the apparent place of γ *Draconis* by the aberration of light. This star happens to be situate within about 16° of the pole of the ecliptic; it will, therefore, in accordance with the preceding account of aberration, appear to describe nearly a small circle about the place it would have if the earth had no motion, which is called its *mean place*. In the maps of the stars, published by the Useful Knowledge Society, the little circle, which represents γ *Draconis*, will do well enough to give an idea of the path which it describes every year. By measuring the star's zenith distance when on the meridian, its *polar* distance was also measured, since the zenith and pole are both points of the meridian, distant from one another by the *colatitude* of the place [COMPLEMENT]; in other words, by adding the difference between 90° and the latitude of Kew to the meridional zenith distance of the star at that place, we obtain its polar distance. In *fig.* 4, S represents the mean place of the star and $v\ s\ a\ w$ the small ellipse, nearly a circle, described by the star in one year. The reader must imagine this circle placed in the heavens, and the line P S bent over his head, so that Z is his zenith and P the pole. We must now show how to find the points of the ellipse $v\ s\ a\ w$, answering to the four principal periods of the year —namely, the solstices and equinoxes. Referring back to *fig.* 3, in which we finally placed the spectator at S, the sun will appear to describe the circle which the earth really describes; that is, as the earth moves from Q to R, the sun will appear to move from P to T. Hence, when the earth is at Q, the aberration, throwing the apparent place of the star towards S R, 90° *before* the earth, throws it also towards a line 90° *behind* the sun's *apparent* place. Let E, *fig.* 5, be

* The displacement remarked by Flamsteed was evidently due to aberration. This has recently been established beyond doubt by Dr. Peters, who, by a discussion of Flamsteed's observations of the pole star, found the maximum value of aberration to be 20"·676, with a probable error of 1"·11. The close agreement of this result with the mean of the most trustworthy values of the same element hitherto obtained, furnishes a favourable proof of the accuracy of Flamsteed's observations.

the earth, W V S A the apparent course of the sun or the ecliptic, E P the axis of the earth, A M V N the equator; whence, if the sun move in the direction indicated by the arrows, V is the vernal equinox, S the summer solstice, A the autumnal equinox, and W the winter solstice.

Fig. 4.

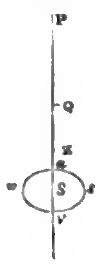


Fig. 5.

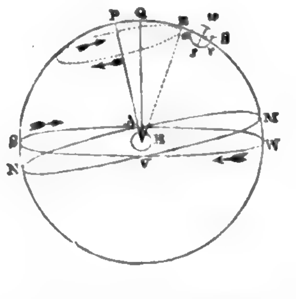


The circle which bounds the whole figure is the *solstitial colure*, and as the star γ *Draconis* is very nearly on that colure, we will suppose it to be at S. Let Z be the spectator's zenith; that is, let him be on such a part of the earth that the plumb-line falls in the direction Z E, the point Z will, by the motion of the earth, be carried round the dotted circle. The meridian is the moving circle passing through P and Z, and as the figure stands, the real star and the pole of the ecliptic are on the meridian. First, let the time be the vernal equinox, or let the sun appear at V; then the point W being 90° behind V, the star will appear to be thrown towards W, and its apparent place is *v*. Similarly, *s*, *a*, and *w* are the apparent places corresponding to S, A, and W, the dotted part of the ellipse being supposed to be bent over on the other side of the sphere. *Fig.* 4 is taken from *fig.* 5, and is the course of the star, as it will appear to the spectator at E, S Q P being bent, so that Z is over his head, and P behind him. Let us now suppose him in the situation of Bradley, with an instrument capable only of measuring changes in the polar distance, the time being the winter solstice. As the star appears to move from *w* to *v*, which takes place between this and the vernal equinox, the polar distance will increase from day to day; after the vernal equinox it will decrease, and continue to do so until the autumnal equinox; after which, it will increase again till the winter solstice. This is precisely the phenomenon observed by Bradley, who clearly perceived that it could not be attributable to the annual parallax of the star. To illustrate this, let us suppose that when the earth is at Q (*fig.* 3), we look at the star in the direction Q G, and when it is at P we look at it in the direction P F. Draw P H parallel to Q G: the spectator, who imagines himself at rest, will, if he observes the star at these two epochs, see the difference of position corresponding to the angle H P F, at least if the distance of the star be not so great as to render that angle imperceptible to his instruments. This however will take place in the plane passing through the star and P Q, whereas, the effect observed by Bradley took place in a direction perpendicular to that plane.

The displacement of γ *Draconis*, observed by Bradley at Kew, was confirmed by subsequent observations which he made at Wanstead, in Essex, with an instrument of similar construction. The question now occurred, to what was the phenomenon attributable? At first he suspected that it arose from some irregularity in the instrument, or deviation of the plumb line, and afterwards from some *nutation*, or conical motion of the earth's axis. These, however, he found would not account for the observed displacement of the star. "At last, when he despaired of being able to account for the phenomenon which he had observed, a satisfactory explanation occurred to him all at once when he was not in search of it. (Thomson, 'History of the Royal Society,' p. 346.) He accompanied a pleasure-party in a sail upon the river Thames. The boat in which they were was provided with a mast which had a vane at the top of it. It blew a moderate wind, and the party sailed up and down the river for a considerable time. Dr. Bradley remarked, that every time the boat put about, the vane at the top of the boat's mast shifted a little, as if there had been a slight change in the direction of the wind. He observed this three or four times without speaking; at last he mentioned it to the sailors, and expressed his surprise that the wind should shift so regularly every time they put about. The sailors told him that the wind had not shifted, but that the apparent change was owing to the change in the direction of the boat, and assured him that the same thing invariably happened in all cases." * While pondering on the circumstance, it occurred to him that the velocity of light, combined with the motion of the earth in its orbit, must produce a similar minute change in the apparent places of the stars, and thus he was led to his great discovery of aberration.

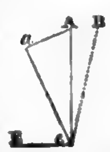
The greatest aberration, as we have observed, is parallel to the ecliptic, and is the greatest semi-diameter of the apparent annual ellipse of a star. This ought to be the same for all stars, if the rays which come from them move with the same velocity. Hitherto it has not been discovered that the greatest aberrations of different stars differ by more than may reasonably be imputed to instrumental errors; we must therefore conclude that, as far as we know, the light of every star moves with the same velocity.

Bradley, in the early period of his researches, fixed the maximum value of aberration at 20"·25, but ultimately he adopted 20"·0 as the most probable value. Delambre, from observations of the eclipses of Jupiter's satellites, determined it to be 20"·255. Bessel, by a discussion of Bradley's observations ('Fundamenta Astronomiæ,' 1818) found the maximum value to be 20"·7080, but in the 'Tabulæ Regiomontanæ' (1830), he has adopted Delambre's result. In recent times various astronomers have investigated the value of the constant of aberration, and have obtained results which generally fluctuate between these two extremes. In the Introduction to the 'British Association Catalogue of Stars' (1844), Mr. Bailey has compared together all the most trustworthy determinations, and hence deduces 20"·4192 as the most probable value. The result generally adopted by astronomers in the present day is due to M. Struve, Director of the Imperial Observatory of Pulkowa, who has found the maximum aberration to amount to 20"·445 by a discussion of observations recently made at that observatory with a transit instrument placed in the prime vertical. [TRANSIT INSTRUMENT.] This result agrees very nearly with that obtained about the same time by Dr. Peters, who, from observations made at the Pulkowa observatory with a vertical circle by Ertel [CIRCLE], determined the maximum value of aberration to be 20"·481.

The aberration of light has furnished astronomers with what has been always regarded a desideratum since the establishment of the true system of the universe by Copernicus—an incontrovertible proof of the annual motion of the earth. In recent times, M. Foucault, an eminent French physicist, has given two distinct demonstrations of the diurnal motion, founded on the doctrine of rotation. [GYROSCOPE; PENDULUM.]

It is well known that solar light is composed of several colours, which admit of separation from one another. The light of the stars is also compounded of several colours; for though different tinges predominate in different stars, no one gives a perfectly pure colour. The phenomenon of aberration proves that these different lights move with the same velocity; for two lights, moving with different velocities from the same star, would give different quantities of aberration; that is, would make differently coloured images of the star in different places, that image being nearest to the real place of the star, the colour of which moves with the greatest velocity. But as no indication of such an appearance is observable in the very best telescopes, we are, therefore, bound to conclude, that all the different coloured light of which white light is composed, moves with the same velocity. For the determination of the velocity of light from the aberration, see LIGHT.

We have hitherto considered only the case of a star which has no motion of its own; let us now take that of a planet, comet, or the moon, which moves while the earth moves. Let the planet move from A to *a*, and the earth from E to *e*, in the time which it takes the light to move from the planet to the earth. Then, by what has been said, the earth at *e* receives the ray A*e*, which is imagined to be in the direction B*e*; and if the planet had remained fixed at A, A*e*B would have been the aberration, or the angle contained between its true and its apparent direction. But in the meanwhile the planet has moved to *a*, and if light were transmitted instantaneously would appear in the direction *e a*. Hence *a e* B is the aberration; that is, to the former angle, the planet's motion round *e*, during the passage of the light, must be added or subtracted, according as the earth and planet move in the contrary or same directions. The greatest aberration of Mercury is nearly one minute; that of the moon, only two-thirds of a second. To the sun, which has no motion of its own, the rule for a star in the ecliptic may be applied; recollecting, however, that as a line drawn from the sun to the earth is always at right angles, or very nearly so, to the direction of the earth's motion, the aberration is always at its greatest value, or nearly so, and is nearly 20¼".



In the preceding account we have omitted two circumstances, which would only have perplexed the reader. Firstly, every star changes its place on account of the precession of the equinoxes. [PRECESSION.] This was known to Bradley, who was therefore obliged to allow for this change, before he could pretend to assign that arising from any other phenomenon; secondly, the motion of the earth not being perfectly circular, but slightly elliptical, the quantity of aberration must be a little modified on that account. The effect of this will be seen in the article REDUCTION.

ABERRATION, in Optics. The most perfect mirror, or lens, which could be made, would be one in which all the rays which come from one point should be reflected or refracted to another point. Owing to the practical difficulties in the way of forming such a mirror or lens, the spherical form is adopted, of which it can only be said, that instead of returning to a point all the rays coming from a point, it condenses so many of them near a particular point, that an apparent image is formed at that point. The point near which most rays are collected is called the focus, and the distance at which a ray cuts any line passing through the focus is called its aberration with respect to that line. For a discussion of this subject, see LENS. Again, when light is refracted through any transparent medium, its different colours have

* The original authority for this account is said to be Dr. Robison ('Natural Philosophy,' vol. iv. p. 629), who probably received it from Bradley himself.

different foci; for the cause and phenomena of which see ACHROMATIC. The aberrations arising from these two causes are generally known by the names of *spherical aberration* and *chromatic aberration*.

ABETTOR. The etymology of this word is somewhat uncertain; it may be derived from the Saxon *betan*, to push forward, or incite. An abettor is an instigator or setter on—one that procures another to commit a crime. If an abettor, or, as he is then usually termed, aider and abettor, be present at the time of committing the crime, he is treated as a principal; if absent, he becomes an accessary before the fact. [ACCESSARY.]

ABEYANCE is a legal term, derived from the French *bayer*, which, says Richelet, means to "look at anything with mouth wide open." Coke ('Co. Litt.' 342, b.) explains the term thus, "*En abeiance*, that is, in expectation, of the French *bayer*, to expect. For when a parson dieth, we say that the freehold is in abeyance, because a successor is in expectation to take it; and here note the necessity of the true interpretation of words. If tenant *pur terme d'autre vie* dieth, the freehold is said to be in abeyance until the occupant entereth. If a man makes a lease for life, the remainder to the right heirs of J. S., the fee-simple is in abeyance until J. S. dieth. And so in the case of the parson, the fee and right is in abeyance, that is, in expectation, in remembrance, entendment or consideration of law, *in consideratione sive intelligentia legis;* because it is not in any man living."

The expression that the freehold or the inheritance of an estate is in abeyance, therefore, means that there is no person in whom the freehold or inheritance is vested at the moment, and that the freehold or inheritance is waiting or expecting for an owner who is to be ascertained. This doctrine of the suspense of the freehold or inheritance is repugnant to the general principles of the tenure of land in England. By the old law, it was necessary that some person should always be in existence as the representative of the freehold, for the discharge of the feudal duties, and to answer the actions which might be brought for the fief; and thus the maxim arose that the freehold could never be in abeyance. The case of glebe lands belonging to parsons, and of lands held by bishops and other corporations sole were scarcely exceptions, for the *corporation* always existed, although the individual parson or bishop was not yet named.

Titles of honour are also sometimes said to be in abeyance, which occurs when the persons next in inheritance to the last possessor are several females or co-parceners. In this case, the title is not extinct, but is said to be in abeyance; and may be called out of abeyance at any time by the crown. Several instances of the exercise of this prerogative are on record both in ancient and modern times.

(*Camoys's Case*, 5 Bing. *N. C.* 754; *Coke upon Littleton*, 165; Cruise, *Digest*, vol. i. pp. 52, 55; *Report of Committee of House of Lords*, *Sess.* 1858.)

ABIB, the first month of the Hebrew year, now more generally known by the Chaldee name Nisan. [NISAN.]

ABIETINE (Formula unknown), a neutral resin, extracted from Canada balsam and Strasbourg turpentine. It is inodorous and tasteless; soluble in alcohol, concentrated acetic acid, ether, and naphtha, but insoluble in water. It fuses on being heated, and assumes the form of a crystalline mass on cooling. Caustic potash has no action upon it. (See 'Journ. de Pharm.,' xvi. 436.)

ABJURATION OF THE REALM signifies a sworn banishment, or the taking of an oath to renounce and depart from the realm for ever. By the common law of England, if a person guilty of any felony, excepting sacrilege, fled to a parish church or churchyard for sanctuary, he might, within forty days afterwards, go clothed in sackcloth before the coroner, confess the full particulars of his guilt, and take an oath to abjure the kingdom for ever, and not to return without the king's licence. Upon making his confession and taking this oath, he became attainted of the felony; he had forty days from the day of his appearance before the coroner to prepare for his departure, and the coroner assigned him such port as he chose for his embarkation, to which he was bound to repair immediately with a cross in his hand, and to embark with all convenient speed. If he did not go immediately out of the kingdom, or if he afterwards returned into England without licence, he might suffer death as a felon, unless he happened to be a clerk, in which case he was allowed the benefit of clergy. This practice, which has obvious marks of a religious origin, was by several regulations in the reign of Henry VIII., in a great measure discontinued, and at length, by statute 21 James I. c. 28, the privilege of sanctuary was entirely abolished. In the reign of Queen Elizabeth, however, Roman Catholics and Protestant Dissenters convicted of having refused to attend the divine service of the Church of England, might be required to *abjure the realm*, and if they refused to swear, or to depart, or returned without licence after their departure, they were to be adjudged felons, and to suffer death without benefit of clergy. The punishment inflicted by stat. 35 Eliz. c. 2, was thus more severe than that imposed for a return after adjuration at the common law, for in the latter case the felon had the benefit of clergy; in the former, it was expressly taken away; but the circumstances which called for the act must not be forgotten. Protestant Dissenters were exempted from this statute by the Toleration Act, 1 Wm. III. c. 18; but Popish recusants convict continued liable to be called upon to abjure the realm for their recusancy, until the statute 31 Geo. III., c. 32 (1791), relieved them from that and many other penal restrictions, upon their taking the oaths of allegiance and abjuration.

ABJURATION, OATH OF, is an oath which asserts the title of the present royal family to the crown of England. It was first imposed by 13 & 14 Will. III., c. 6; altered by 1 Anne, st. 1. c. 22, and amended again by 1 Geo. I., stat. 2, c. 13. The person taking the oath recognised the right of the king under the Act of Settlement, engaged to support him to the utmost of the juror's power, promised to disclose all traitorous conspiracies against him, and disclaimed any right to the crown of England by the descendants of the Pretender. The juror next declared that he rejected the opinion that princes excommunicated by the Pope might be deposed and murdered; that he did not believe that the Pope of Rome or any other foreign prince, prelate, or person, had or ought to have jurisdiction, directly or indirectly, within the realm. Persons required to take the oath of abjuration were generally obliged to take at the same time the oaths of allegiance and supremacy. All these oaths have now been simplified and reduced to one form by the statute 21 & 22 Vict., c. 48. The form of oath to be taken by a Roman Catholic is given in 10 Geo. IV., c. 7 (the Roman Catholic Relief Act). The first part of the oath is similar in substance to the form required by 6 Geo. III. c. 53. The taker disclaims, disavows, and solemnly abjures any intention to subvert the present Church Establishment as settled by law within the realm; and solemnly swears that he will never exercise any privilege to which he is or may become entitled to disturb or weaken the Protestant religion or Protestant government in the United Kingdom; and solemnly, in the presence of God, professes, testifies, and declares that he makes this declaration, and every part thereof, in the plain and ordinary sense of the words of the oath, without any evasion, equivocation, or mental reservation whatever.

The word *abjuratio* does not occur in classical Latin writers, and the verb *abjurare*, which often occurs, signifies to deny a thing falsely upon oath.

ABLATIVE CASE, a term borrowed from the grammatical system of the Latin language, and occasionally employed in teaching our own. In the English Language there are many little words, such as *with, in, to, at*, &c., which are called *prepositions*, because they are *preposed* or prefixed to the words with which they are connected. The name however is an unfortunate one, as they are sometimes found *postponed* or placed after such words, especially in the older specimens of our language. We say *with which* or *wherewith, in which* or *wherein, from which* or *wherefrom.* So, in the Latin language, a certain set of little words, with the force of prepositions, were tacked on to the end of their nouns: thus, while the three letters, *reg*, meant *king* (whence our word *reg-al*), *reg-is* meant *of* or *from a king*—*reg-i, with, in*, or *near a king*—*reg-em, to a king.* Thus the three little words, *is, i, em*, were equivalent to prepositions. It pleased the grammarians however, who are fond of multiplying names, to call these words *reg-is, reg-i*, &c., by the name of *cases.* The meaning of the endings of these words was not always definite enough. Thus with the case in *i* for instance, it was found necessary to mark the relation of place more precisely by the addition of other words, as *in, in*—*pro, before*—*cum, with.* Thus they would have, *in regi, in the king; pro regi, before the king; cum regi, with the king.* Now, as *in, pro, cum*, were much more definite than the termination *i*, it became unnecessary to make the *i* distinctly heard. It was no longer necessary to the meaning, and might therefore be slurred over: hence the pronunciation was reduced to *in rege* (the last *e* very faintly pronounced), *pro rege, cum rege.* But we have so far dealt only with those cases where the so-called ablative grew out of a case in *i*, commonly called the dative. There was, however, another case-ending, of different form and very different power, which in the end got similarly corrupted. This, in old Latin, had a final *d*, as *Gnaivod patre prognatus*, afterwards *Cnaeo*, &c., *sprung from a father Cnaeus.* In Sanscrit this *d* is represented by a *t*, as *mat, from me, tvat, from thee.* Bopp indeed (V. G. § 340) regards the original suffix of the Sanscrit as *tas*, afterwards reduced to a *t*, and further holds that this *tas* corresponds on the one hand to the Homeric θεν of εμεθεν, σεθεν, and on the other to the Latin *tus*, as seen in *caelitus, from heaven.* Be this as it may, it seems pretty certain that in the so-called ablative of the Latin there are blended what were originally two distinct cases; first, a true ablative, once ending in *d* with the sense of *from*, so as to justify the use of the case after prepositions of removal, as *ex rege, ab rege, de rege*, as well as *Corintho fugit, he fled from Corinth;* secondly, what was more properly a dative, or rather locative, answering to the question *where*, as in the examples already given with the prepositions of rest, *cum, with, pro, before, in, in.* The fact that two independent cases have slipped into an identity of form is not rare in language. We have an example of such confusion in one of our own pronouns, as in *he gave him a book*, where *him* is a dative, corresponding to the German *ihm;* and *he gave him to the constable*, where *him* is an accusative, corresponding to the German *ihn.*

ABLUTION, literally *a washing away*—a religious ceremony, consisting in bathing the body, or a part of it, in water, which has been practised more or less extensively by the disciples of almost every form of faith. Among outward types, none can be conceived more natural or appropriate as a sign or attempted representation of mental purity. The custom, particularly in the warm climates where it was first introduced, had also the further advantage of being highly conducive to health; and this circumstance no doubt contributed powerfully to recommend it to the authors of many of the religions by which it was sanctioned and enjoined. Ablutions, or *lustrations*, as they are more commonly called, even constituted a part of the Mosaic ceremonial, and were practised among the Jews on various occasions both by the priests and by the people. They occupy an important place in the Brahminical and other religions of India, where the waters of the Ganges are considered as having so purifying a power, that even if a votary, who cannot go to that river, shall call upon it to cleanse him, in prayer, while bathing in another stream, he will be freed from any sin or pollution he may have contracted. But the religion by which ablutions have been enjoined most punctiliously, and in the greatest number, is the Mohammedan. According to the precepts of the most rigid doctors of that faith, it may almost be said that scarcely the most ordinary or trifling action can be rightly performed without being either preceded or followed by an entire or partial lustration. The rules laid down upon the subject by these writers are minute and tedious, to a degree scarcely to be believed. The simple ceremony of Christian baptism may be regarded as an adoption of this natural type by the Author of our faith. Although, however, that is the only instance in which dipping in or sprinkling with water has been enjoined under the dispensation of the New Testament, the early Christians appear to have been also in the habit of undergoing ablution with water before partaking of the communion. The sprinkling with holy water, in use in the Roman Catholic church, may be considered as a species of ablution; and as a liturgical term it is applied in that church to the wine and water used by the priest to cleanse his fingers, and the chalice, after having administered the sacrament. In the Greek church, ablution sometimes means the wine and water given to the communicant, the better to be enabled to swallow the holy wafer.

ABORTION. [INFANTICIDE.]

ABRAHAM MEN. To 'sham Abraham' is a well-known cant expression, which has reference to the practices of a large class of vagabonds and cheats who were once common in this country. An Abraham Man was an impostor who personated a 'Tom of Bedlam,'—an unhappy being who was turned out of a lunatic asylum to subsist upon casual alms, incurable but harmless, without a home, but still maintained by public sympathy. This class of persons was so numerous at a period when there was very insufficient provision for the cure or mitigation of the greatest of human calamities, that the charity of the kind-hearted inhabitants of the small towns and villages was largely taxed for their support; and the appeal thus made to the feelings by a poor creature, fantastically clothed in tawdry rags, and singing snatches of old songs, was so irresistible, that it became a profitable trade to imitate such an unfortunate being. In Decker's 'English Villainies,' written more than two centuries ago, there are many curious particulars of the habits of this class of impostors; these details, in great part, agree with the rich description which Shakspere has given in his 'Lear,' (Act. ii. scene 3.) of a pretended 'Poor Tom,' who has put on

> "The basest and most poorest shape,
> That ever penury, in contempt of man,
> Brought near to beast."

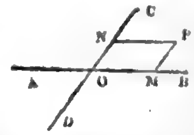
ABSCESS, (from a Latin word, *Abscedo*, implying separation,) is so called, because parts which were in contact have become separated. An abscess consists of a collection of the matter termed pus, in some tissue, or organ of the body. Purulent matter, or pus, is formed out of the lymph separated from the blood during the process of inflammation. The production of pus during the progress of inflammation is called suppuration. [INFLAMMATION.]

The purulent matter constituting an abscess, properly so called, is always confined within a definite space: the means by which it is confined vary. Sometimes the purulent matter is effused into the substance of an organ; in this case some portion of that part of the blood which is called *fibrin*, or coagulable lymph, is effused with it; this fibrin coagulates into a firm solid membrane, encloses the pus, and so prevents its diffusion. Sometimes the effused fibrin, or coagulable lymph, becomes organised; in this case it forms a new membrane, which is called an *adventitious* membrane, and the pus is completely enclosed in this new membrane as in a bag, or shut sac or *cyst*: an abscess of this kind is called an *encysted* abscess, and the internal surface of this cyst is always endowed with the properties both of absorption and of secretion; for large collections of matter, enclosed in bags of this kind, occasionally disappear without any external opening; and on the other hand, when such a bag has been completely emptied of its contents, it is sometimes rapidly refilled with pus. When an opening is formed in an abscess, and purulent matter continues to be discharged from it, it loses the name of abscess, and takes that of ulcer.

Purulent matter is poured out from the blood in other modes, and forms other collections of pus; but these latter collections are never called abscesses. Sometimes, for example, the pus, as it is secreted from the blood, is diffused through the substance of the inflamed organ. This is the case especially with the lung during the progress of inflammation. This diffusion of purulent matter through the substance of an inflamed organ is termed INFILTRATION and, instead of containing an abscess, the organ is said to have pus infiltrated through it. This is also seen in phlegmonous erysipelas.

There are few tissues of the body, and still fewer organs, in which abscesses may not form. They are found in the brain, the lungs, the heart, the liver, the spleen, the uterus, the ovaria, the cellular membrane, and the joints. In some of these organs the disease is highly dangerous, in others certainly fatal, in others comparatively unimportant. [INFLAMMATION.]

ABSCISSA, or LINEA ABSCISSA, a line cut off, is a mathematical term, used as follows: If any two right lines A B, C D, be given, meeting in O, the position of any point, P, in the plane of those lines, is known when we know, first, within which of the four angles, B O C, C O A, A O D, D O B, it lies, and, secondly, what is its distance from each line, measured on a line parallel to the other; or, in other words, what are the sides of the parallelogram O M P N. Either of these sides being called the *abscissa*, the other is called the *ordinate;* both are called *co-ordinates;* the straight lines, A B and C D, are called the *axes*, and O is called the *origin*. It is customary to denote the lengths of the abscissa and ordinate by the letters x and y respectively. Thus O M being the abscissa of the point P, P M is its ordinate. All points in the line P M have the same abscissa; all those in P N the same ordinate. [CO-ORDINATES.]



ABSENTEE. This is the first subject, in alphabetical order, that comes under our notice in the science of political economy. In the whole compass of that science there is no subject which presents more difficulties in the way of popular explanation, if we view it purely as a scientific question. An absentee, as the term is now used, is a person who derives his income from one country, but resides in another country where he expends that income. The common voice of mankind says that this is an evil and an injustice. It points to lands imperfectly cultivated, to labourers inadequately employed, to ruined cottages, to uneducated children, and it proclaims that these things would not be if the proprietor resided upon his estates. He does not choose to reside upon his estates; he would rather derive less from his estates, having the liberty to spend the revenue as he pleases. There is no law to prevent him but the great law of moral obligation, which he may obey or not. The public inconveniences of a positive law to bind his person to his property would far outweigh its public good. But the common sense of mankind is right; and the day of retribution comes when neglect goes forward into general destitution. Then the capital which has been abstracted from its fertilising local influence, is forcibly driven back, to prevent misery becoming utter ruin. Such results have been shown in large districts of Ireland. The political economists of every class cannot shut their eyes to these facts; but some say that these facts lie beyond the boundaries of their science; they belong to the moralist to explain. They consent only to look at the absentee in his abstract capacity of a capitalist; they admit that it would be better for his own local connections and dependants that he should not be an absentee; but they are prepared to prove that it is a matter of indifference to the country in general; that the wealth of the country is neither increased nor diminished whether he spend his rents in Dublin or in London—in London or in Rome. Even in this point of view these economists have few supporters. Popular opinion, without pointing to the extreme moral evils of a non-resident landed proprietary, maintains that the amount of revenue which the landlord spends in a foreign country is so much clear loss to the country from which he derives his property, and so much encouragement withdrawn from its industry; and that he ought therefore to be compelled to stay at home, instead of draining his native land for the support of foreign rivals. Some political economists reply, that this is a popular delusion, and that, in point of fact, the revenue spent by the landlord in a foreign country has precisely the same effect upon the industry of his own country as if his consumption took place at home. The truth perhaps lies between these counter opinions. The argument of the economists runs thus: all consumers residing in their own country, and landlords amongst the number, purchase many articles of foreign production which have been exchanged for the productions of their own country. In purchasing such foreign productions they stimulate native industry; in taking from foreigners what they produce cheaper and better than we can, and in sending them in exchange what we can produce cheaper and better than they can, we develop a wider field of industry for our native productions, and obtain a larger store of commodities for our home necessities. The consumption of an English resident in a foreign state, they go on to say, produces, in principle, the same indirect effects upon English industry, as his partial or entire consumption of foreign goods in England. His consumption of foreign goods abroad is equivalent to an importation of foreign goods into England; and that consumption, it is said, produces a correspondent exportation of English goods to the foreigner. For why? There must be an export of English goods to some country to the amount of the foreign goods which he consumes, otherwise his remittances could not be made to him. For example, England owes half a year's rent to the resident at Brussels; he draws a bill upon England, which a banker discounts, and sells to a merchant at Antwerp, who wants the bill to pay for goods which Antwerp owes to England; and so, say the economists, England keeps the rent after all; and it stimulates industry as much as if it had been spent in England at first. It does little, they say, to stimulate industry in either case, for it is equally unproductive consumption. It has been a notion amongst a class of political economists, which is fast yielding to sounder notions, that all expenditure is unproductive unless it be incurred directly in the aid of further production. The truth is becoming apparent, that it is impossible to limit productive expenditure by such narrow laws—to say that the man who spends *100l.* in clothes is an unproductive consumer, whilst the tailor who spends *50l.* in cloth and labour for the clothes is a productive consumer. The one could not exist without the other. The one has enabled the other to make a profit upon the clothes, and part of that profit may become accumulation as certainly as if the buyer of clothes had been satisfied with half his wardrobe [CAPITAL]; and this shows the fallacy that lies at the bottom of the absentee argument. The absentee withdraws the local profit of those who have a natural claim to supply his wants. It may be true, that the foreigner requires some additional goods from England in consequence of the domiciliation of the English absentee; but does he require as large an amount of English goods as the total sum which the Englishman expends? Unquestionably not. There are large differences between the exchanges of commerce and the smaller exchanges of domestic life. The profit of the foreign retailers, of the foreign domestic servants, of the foreign landlord of the absentee's house, remain at any rate to the foreign country, and are so much abstracted from the absentee's country. By abstracting the profit of these smaller transactions, the surplus that becomes accumulation remains in the shape of new capital to the foreign country. New capital in a country is created by the slow aggregation of minute individual profit. Profit is like the nitrogenous substances in the food of men. Individuals may exist feebly and miserably without profit from their labour—that is, their labour may replace what they consume, and leave no surplus—as individuals may drag on existence upon the innutritious root which imperfectly replaces their ordinary exhaustion, and leaves nothing for development or extraordinary exertion. But the wealth of nations cannot be sustained without surplus produce—without profit; as the health of communities cannot be sustained without the food which builds up the body as well as keeps alive the animal heat. Rent is really profit under another name. It is, in most cases, the largest portion of the surplus produce of the soil. It is that surplus which constitutes a natural fund for social improvement. The absentee who withdraws that fund from its local appropriation to make it the source of new profit to a foreign country, even if it be only the profit of supplying his domestic necessities, and not the profit of commercial exchange, to a certain extent must take away what he ought to contribute to the accumulation of his own district and his own country.

(The arguments which deny the injurious effects of absenteeism, merely regarded as a question of political economy, may be seen in Mr. M'Culloch's evidence before the Select Committee on the 'State of Ireland, 1825, Fourth Report,' and his evidence before the Committee on the 'State of the Poor in Ireland, 1830.' The contrary argument may be found in 'Lectures on Political Economy,' by J. A. Lawson, LL.B., Lecture V. 1843.)

ABSINTHINE (Formula, $C_{32}\ H_{22}\ O_{10}$), the bitter principle of the *Artemisia absinthium*. To prepare it, the dried leaves of wormwood are extracted with alcohol of 80 per cent., the extract evaporated to a syrupy consistence and treated with ether; the supernatant ethereal layer must be decanted, and the treatment of the residue with ether repeated until the ethereal extract no longer tastes bitter. This ethereal solution, evaporated on the water bath, leaves a residue composed of absinthine and a resinous body, which latter may be dissolved out by very dilute ammonia. The residual absinthine must be digested with dilute hydrochloric acid, washed with water, and then dissolved in alcohol; to the alcoholic solution acetate of lead must be added until the liquid becomes milky. After filtration, the excess of lead must be removed by sulphuretted hydrogen, and the alcoholic solution, slightly diluted with water, allowed to evaporate spontaneously in a warm place. Yellow resinous drops of absinthine gradually separate, and these finally solidify to a confusedly crystalline mass.

Absinthine has a slight odour of wormwood, and an exceedingly bitter taste. It is very slightly soluble in water, more so in ether, and very soluble in alcohol, and also in concentrated acetic acid. Ammonia dissolves it in very small quantity only, but potash somewhat more freely. It possesses a decidedly acid reaction.

ABSOLUTION, a religious ceremony in use in different Christian communities, by which the priest declares an individual, on repentance and submission to the requisite penance, to be absolved either from his sin, or from the ecclesiastical punishment or deprivation to which it had rendered him liable. It is contended by many theological writers, that down to the twelfth century the priest in this act only used the words "May God, or may Christ, absolve thee;" thus refraining from claiming any authority to remit the sin himself. Since then, however, the formula used in the Roman Catholic church has been *Ego te absolvo a peccatis tuis* (I absolve thee from thy sins), accompanied with the sign of the cross. The Council of Trent has expressly condemned the doctrine that the priest has not power of himself to absolve from the guilt of sin. (Session xiv. Canon 4.) The Church of England employs in the Order for the Visitation of the Sick, words nearly the same with those employed in the Roman Catholic communion, "I absolve thee from all thy sins." It is, however, maintained by the highest authorities that the absolution thus bestowed is only declaratory, while that pronounced by the Roman Catholic priest is professed to be absolute, and to proceed solely from himself. Hooker, 'Ecclesiastical Polity,' B. VI. § 12; who winds up his comparison of the doctrine of his own church with that of the Church of Rome, by saying, "Wherefore the further we wade, the better we see it still appear, that the priest doth never in absolution, no not so much as by way of service and ministry, really either forgive the act, take away the uncleanness, or remove the punishment of sin: but if the party penitent come contrite, he hath by their own grant absolution before absolution; if not contrite, although the priest should ten thousand times absolve him, all were in vain." (*Ibid.* B. VI. § 13.) In the Greek church the formula is merely declaratory; that is to say, it is of the nature of a prayer to heaven that the sins of the penitent person may not be visited with their due punishment. It is so also in the Protestant Church of Scotland; and there the term absolution is commonly used to denote simply the declaration of the Kirk-Session or other judicatory, expressed by the mouth of its president, that the party is released from the ecclesiastical interdict to which his delinquency had subjected him.

In the early church there were held to be five kinds of absolution: by baptism; by the eucharist; declaratory, by word of mouth and doctrine; precatory, by imposition of hands and prayer; judicial, by relaxation of church censures.

The Absolution as it now stands in the order for Morning and Evening Prayer was first inserted in the Second Book of Edward VI. On a subsequent revision the word *minister* was changed into *priest*. The other two absolutions are coeval with the reformed Prayer Book.

ABSORPTION (from *absorbeo*, to *suck up*) is the process by which rays of heat are made to disappear. The surfaces of different bodies vary greatly in absorbing power, and even in the same body the power varies with the state of the surface as to colour, roughness, &c. The subject will be considered in its proper place under HEAT.

ABSORPTION OF LIGHT is that process which takes place when light enters an imperfectly transparent medium, in virtue of which a portion of the light is continually stifled, or spent in producing some physical effect, while the remainder is either directly transmitted, or emerges after one or more internal reflections.

A body absorbing all the light incident upon it would appear black, and would be wholly invisible; though, in point of fact, the blackest body actually existing reflects some light from its surface; while a body absorbing none, but reflecting light of all kinds indifferently from a multitude of irregularly placed surfaces, would appear white like snow. In general, the different component parts of white light are absorbed with unequal energy, and thus the light which escapes absorption is coloured, as not containing the colours of the spectrum in the proper proportion to form white light. In the great majority of cases the colours of natural bodies are occasioned in this way.

When light of any one kind enters a homogeneous medium, its intensity decreases in geometric progression as the length of its path within the medium increases in arithmetic in progression. This readily follows from the fact that in any given case the quantity of light lost by absorption is a given fraction of the quantity originally incident. (See Herschel on Light, 'Encyclopædia Metropolitana,' art. *Absorption*.) Accordingly, in being transmitted directly across a stratum of the medium of thickness t, the intensity is reduced in the ratio of 1 to r^t, where r is a fraction less than 1, or at most equal to 1. The quantity r varies from one medium to another, and for the same medium from light of one refrangibility to light of another. If $r = 1$ for light of all kinds, the medium is colourless and transparent, like water, which for ordinary purposes may be regarded as such. If r were less than 1, but the same for light of all kinds, the medium, in a stratum of sufficient thickness, would cease to transmit light, without becoming coloured in smaller thicknesses; but no such media are known to exist. When r is less than 1, it always varies more or less with the kind of light, and therefore the transmitted light is coloured.

If $a, a', a'' \ldots$ denote the original intensities of the various kinds of light of which white light is made up, $r, r', r'' \ldots$ the different values of the fraction r for those kinds of light, the intensities after transmission will be reduced to $a\,r^t, a'r'^t, a''\,r''^t \ldots$ The relative proportions of these latter will determine the tint of the transmitted light. It is to be remarked, that this tint will change, not only with a change in the absorbing medium, but even while the medium remains the same, with a change in the thickness t. While the total quantity of light transmitted continually decreases as the thickness of the stratum looked through is increased, the colour generally becomes purer and purer, those colours for which r is least becoming more and more predominant. Sometimes however the change of tint with an increase on thickness is very remarkable. Thus, solutions of the chrome salts in general are green in small thickness, and passing through a sort of neutral tint, become red when the thickness is sufficiently increased. The reason of this is easily explained according to the principles just laid down. The green, and a comparatively small quantity of red, are the colours which chiefly escape absorption at an early stage; but as the absorption goes on, the red, being absorbed less rapidly than the green (r being less for a portion of the red than for the green), becomes at length the predominant colour.

The mode of absorption of light by a coloured substance is often eminently characteristic of the substance, but can be judged of only very imperfectly by the tint of the transmitted light. It is easily determined by analysing the transmitted light by means of a prism.

When a body is not homogeneous in structure, but (like chalk or paper) is filled with surfaces capable of reflecting light, a considerable portion of the whole reflected light ordinarily proceeds from a greater or less depth beneath the outer surface. If the material of which the body is composed be one capable of absorbing light, the light reflected from the interior suffers absorption both in penetrating into the body and in getting out again. Accordingly, those colours which the material is least disposed to absorb are found predominating in the reflected light. It is thus that absorption operates in the case of pigments, the petals of flowers, dyed clothes, &c., which exhibit more or less lively colours by reflected light, though in these cases the light reflected strictly at the outer surface is colourless. The tint of the reflected light has a general agreement with that of the light transmitted through sufficiently thin stratum of the coloured material.

Metals may for most purposes be regarded as absolutely opaque; yet even they can sometimes be rendered so thin as to transmit light. Thus, gold-leaf transmits a green or bluish-green light; and the coloration of the light shows that the transmission does not take place merely through the minute holes with which gold-leaf is filled, but actually through the metal. There are good reasons for believing that the strong reflecting power of metals is intimately connected with their intense absorbing power. Thus gold, which absorbs the more refrangible colours with most energy, reflects them also in greatest abundance, so that it is yellow by reflected, while it is bluish-green by transmitted light. Some intensely coloured substances (murexide and platinocyanide of magnesium are good examples) absorb the colours of *a part* of the spectrum almost as intensely as metals, while for other parts they are comparatively transparent, and reflect the colours for which they have an intense absorbing power with an energy comparable with metals: while other colours are reflected only as they would be by vitreous substances. Hence the *regularly* reflected light is brilliantly coloured; but the predominant colour is that of the light *most intensely* absorbed. This is just the reverse of what takes place in the case of the light reflected from the petals of flowers, &c., where the coloration is due, not to reflection, but to absorption, and the colour is that due to the light for which the absorbing power of the colouring substance is *least*. (See a paper by M. Haidinger in the Proceedings of the Academy at Vienna. 'Sitzungsberichte,' Bd. 8, S. 97. See also 'Phil. Mag.,' S. 4, vol. vi., pp. 284 and 393.)

When a doubly refracting crystal is coloured, it often happens that the two pencils which, in any given direction within the crystal, are capable of being transmitted independently of each other, are very differently absorbed. Thus a plate of tourmaline cut parallel to the axis stops more or less completely light polarised parallel to the axis, constituting the ordinary ray, and lets through light polarised perpendicularly to the axis, constituting the extraordinary ray. In some specimens, with plates of a suitable thickness, the stoppage and transmission respectively are tolerably perfect, which makes such a plate very valuable in experiments on polarisation. That the effect is really one of absorption may be shown by using, instead of a plate bounded by parallel surfaces, a thin wedge tapering to a mere line, and viewing it separately by light polarised parallel and perpendicularly to the axis. It is found that quite close to the edge the crystal is colourless and transparent for both pencils; but that as the distance from the edge increases, the ordinary pencil becomes rapidly more and more absorbed, while the absorption of the extraordinary comes on but slowly. As usual in absorption, the different colours are unequally absorbed; and not only so, but the colours which are most absorbed are different for the ordinary and extraordinary rays, so that the crystal is commonly differently coloured with regard to the two pencils, which may be observed at the same moment, but separately, by viewing the crystal through a double-image prism. The mode of absorption changes, not only in a given direction within the crystal in passing from the ordinary to the extraordinary ray, but also in passing from one direction to another. Dr. Wollaston appears to have first observed ('Phil. Trans.,' 1804, p. 428) that the light transmitted along the axis of a crystal of tourmaline had a colour different from that of the light transmitted perpendicularly to the axis. Several uniaxal crystals (such as smoky quartz, &c.) agree with tourmaline in the general character of the absorption which takes place in them. The colour, and generally the mode of absorption, of the ordinary ray is alike in all directions; that of the extraordinary varies from that of the ordinary, which it has in the direction of the axis, to that most different from the ordinary, which it has in any direction perpendicular to the axis. Many biaxal crystals have a similar property, but the variation of the colour with the direction is more complicated, and in particular some very curious appearances are observed about the optic axes. (See a paper by Sir David Brewster, 'Phil. Trans.,' 1819, p. 11.) M. Haidinger has shown that in biaxal crystals (or at least in those which are symmetrical with respect to three rectangular planes) there are *three* fundamental modes of absorption, symmetrically related to the principal axes, seen each in *any* direction perpendicular to the axis in question by light polarised perpendicular to that axis.

M. de Senarmont has recently shown ('Annales de Chimie,' S. 3, tom. xli. p. 319) that the power of double absorption may be conferred on naturally colourless crystals by a small amount of foreign impurity. A very remarkable example is afforded by nitrate of strontia coloured red by crystallising out of an infusion of logwood.

ABSTINENCE, from *abstineo*, to abstain. The term abstinence signifies a total, or an excessive privation of food. The constituent matter of the body is in a state of continual change—the old particles are constantly taken up and carried out of the system, while new particles are as regularly deposited in their room to repair the loss. The source of these new particles is the aliment or food; but a second office is performed by the aliment scarcely less important than that of furnishing new matter for the renovation of the system. All the organs of the body are excited to the performance of their functions by certain external agents, which are called stimulants; such as air, water, heat, and so on; but of these stimulants the aliment is among the most indispensable and the most powerful. Upon the quantity and quality of the aliment depend the quantity and quality of the blood, and upon the quantity and quality of the blood depends in a great measure the energy of all the functions of all the organs. Any material change in the diet must necessarily produce a powerful impression on the system. Life can be maintained but for a short period under the total privation of food, while the excessive privation of it produces effects upon the system which have not been often observed with accuracy, but which are remarkably uniform, and highly curious and instructive. Opportunities occasionally occur of noting these effects with correctness and completeness, when, for example, the passage to the stomach is closed up by disease; or when, owing to an unsound state of mind, the individual refuses to take nourishment.

During the first two or three days after the total abstinence from food, in a person previously in sound health, the suffering from hunger is generally severe. The thirst is also at times distressing, but thirst is not constantly attendant. The pulse during this period remains natural and so does the temperature of the body. All the evacuations are scanty, and take place at distant intervals. After the first two or three days the wasting of the body becomes visible, the fresh colour characteristic of health disappears, and the features and the limbs, instead of being plump and round, are sunk and collapsed. The loss of weight, which increases rapidly, is appreciable, and the progress of the emaciation is striking. The physical debility increases in exact proportion with the emaciation: and the mind becomes weak, confused, wandering, irritable, and at length almost deprived of reason. All this time there is little or no pain from hunger or thirst, or these uneasy sensations return only at intervals, and are seldom acute and never lasting. The pulse at this stage may be a little quickened; it is certainly easily excited; and in like manner the heat, which seldom sinks below the natural standard, is readily parted with,—so that a slight change of the temperature of a room is felt acutely, and produces very uneasy sensations, a fact which demonstrates to the physician the feebleness with which the functions are carried on, no less clearly than the physical debility itself. The most remarkable and curious phenomena which next supervene, are those connected with the intellectual faculties. The loss of power to perceive accurately, and to connect the trains of thought, is followed by decided delirium, which is at first of a low muttering character, similar to that which takes place in the last stage of typhus fever; but this sometimes passes rapidly into furious and even maniacal delirium, requiring coercion, just as a violent paroxysm of madness itself. Generally the delirium is preceded by a state of painful watchfulness and restlessness, it being impossible to procure sleep or quiet; and, finally, the skin becomes intensely hot, the pulse extremely rapid, the emaciation frightful, the debility so great that scarcely the slightest movement can be performed, and at length the individual sinks exhausted, commonly into a state of stupor amounting to that complete and profound insensibility which is technically called coma.

This history of the progressive changes which take place in the system on the total abstraction of food, is illustrated in the most perfect manner, by two cases which fell under the notice of physicians capable of accurately observing and duly appreciating each successive event. Many wonderful stories are on record, of the truth of which there is no sufficient evidence; but the cases to which we refer were observed and recorded by men whose veracity is beyond question, and who were endowed with more than ordinary discrimination and judgment. The record on this account is invaluable, while in itself it is highly curious and instructive.

For the first case we are indebted to Dr. Currie, of Liverpool. In August, 1795, a gentleman of Yorkshire, aged sixty-six, applied to this physician for his assistance, on account of an obstruction in his swallowing food, with which he had been afflicted for ten or twelve months. At first the complaint was slight; it occurred only when he attempted to swallow dry and hard substances; it afterwards extended to solids of every kind; and, at the time he was first seen by his physician, although he was still able to pass down liquids, the quantity he could swallow was not sufficient for his nutrition, and he was considerably reduced. On the introduction of a bougie into the gullet, it passed about two inches easily, but then met with an obstruction which, by a moderate pressure, was overcome. It then passed easily seven or eight inches more, but at the lower part of the tube, towards its termination in the cardia, it met with a firm resistance, which no patience or skill could surmount. This obstruction proceeded from a schirrous tumour, which, gradually increasing at first, diminished the passage, and at length closed it wholly.

On the evening of the 17th of October, a sudden increase of the obstruction came on, and from this time he was able to swallow only a table-spoonful of liquid at a time, and at long intervals. It was with difficulty that he got down seven or eight spoonsful of strong soup in the day, and this quantity gradually diminished. On the thirteenth day from this sudden increase of the obstruction, the passage appeared to be wholly closed.

The patient himself, to the last, was far from despairing of his recovery; and the affectionate friends around him, though they could not but see the issue of the case, yet desired that his life might be prolonged to the uttermost. The following plan was, therefore, adopted with this view. Every morning a clyster was administered, consisting of eight ounces of strong broth, made chiefly of the membranous parts of beef, these being considered the most nutritious, into which were rubbed two yolks of egg, and to which were added forty drops of laudanum. This was repeated in the afternoon, and again in the evening, previously to which, in the evening, he was placed up to the neck in a tepid bath, of which one-fourth was milk, and the rest water; the whole quantity amounting to twenty-four gallons. The temperature was fixed at 96°, to accommodate his sensations, and the time of immersion was gradually prolonged from forty-five minutes to an hour.

After a few days it was found that the retention of the rectum improved, so that the clysters were enlarged to ten ounces of broth, and three yolks of eggs each; to which were added eight ounces of white wine, and the laudanum, which was added to the evening clyster, was gradually increased from sixty to two hundred and fifty drops. Thus the whole of his nutriment for twenty-four hours consisted of thirty ounces of broth, twenty-four ounces of wine, nine yolks of eggs, and from 250 to 380 drops of laudanum, and administered by clyster; with what liquid might be supposed to be taken up in the bath by the absorbents of the surface of the body.

When in tolerable health, at the commencement of his complaint, this gentleman, who was a tall man, and naturally corpulent, weighed 240 lbs. Before the obstruction had become complete, imperfect nutrition had reduced him to the weight of 179 lbs. In twenty days, from the period of the sudden increase of the obstruction, he was reduced to 154 lbs.; on the twenty-fourth day he had lost 5 lbs. more; and at the period when his delirium commenced, that is on the thirty-second day from the night that he ceased to swallow, he weighed 138 lbs., having lost upwards of 100 lbs. of his original weight. He lived four days longer, that is, thirty-six days from the period when the obstruction was supposed to be complete; but during these last four days, no nutriment, in any form or of any kind, was administered; for the rectum no longer retained the clysters, and the administration of the bath appeared, under these circumstances, to be wholly useless.

For a month after the total obstruction of the passage the temperature and the pulse were natural; but on the thirty-second day the pulse became small and frequent; on the following day the eyes lost their common direction, the axis of each being turned towards the nose; he complained that he sometimes saw double, but the sensibility of the retina was increased rather than impaired; for, on the admission of the light of the window, he screamed out, though he had before been accustomed to this light. On the next day there was considerable incoherence of mind; this incoherence passed rapidly into delirium, during the prevalence of which there was a perpetual and indistinct muttering, with great restlessness and agitation; the skin and the extremities were sometimes of a burning heat, and sometimes clammy and cold; the pulse became feeble and irregular; the respiration, which hitherto had been singularly undisturbed, became laborious; and in ninety-six hours after the clysters and all other means of nutrition had been abandoned, he ceased to breathe.

During the whole of this melancholy progress to inevitable death, this unfortunate gentleman complained very little of hunger: occasionally he expressed a wish that he could swallow, but not often nor anxiously; and, when questioned on the subject of his appetite, he always declared that he had no hunger which occasioned any uneasiness. The clysters evidently relieved the sense of hunger, and the opium they contained seemed to have a powerful share in producing this relief. It occasioned quiet and rest after each clyster, and allayed every kind of desire or appetite. Neither was he much disturbed with thirst. This sensation was, indeed, troublesome during the first days of his abstinence; but it abated, and, as he declared, was always removed by the tepid bath, in which he had the most grateful sensations. His spirits were uncommonly even, and his intellect perfectly sound. He occupied himself a good deal in his private concerns; and, as usual, interested himself in public affairs. In order to husband his strength he was confined a good deal to bed; but, till the last few days of his life, he dressed and undressed himself daily, and walked, not only about his room, but through the house. His nights were quiet; his sleep sound, and apparently refreshing. Just before his delirium set in he had very lively dreams, which were all of a pleasant nature; and, in the last conversation he had with his physician, he told him he had had a very gay evening with two Yorkshire baronets whom he named; that they had pushed the bottle about freely; that many jokes had passed, at the recollection of which he laughed heartily, a thing uncommon with him; but it was observable that he was unable, longer than a moment or two, to distinguish this scene which had passed in sleep from a real occurrence; and this state of mind lapsed into delirium from which he never recovered. At this period he was so weak as to be scarcely able to turn himself in bed, to which he had been entirely confined several days, previously to his death.

The second case, which is no less interesting, occurred to Dr. Willan. It was that of a young man of studious and melancholic turn of mind, who being affected with indigestion, undertook voluntarily to live without food. He drank nothing but water flavoured with a little orange juice. He was seen by Dr. Willan on the sixty-first day of his fast: at that time he was emaciated to a most astonishing degree; the muscles of his face were entirely shrunk; his cheek bones stood prominent and distinct, affording a most ghastly appearance; the abdomen was concave from the collapsed state of the intestines; the limbs were reduced to the greatest possible degree of tenuity, and the processes of their bones were easily distinguishable. His whole appearance suggested the idea of a skeleton prepared by drying the muscles upon it in their natural situations. His mind had become imbecile.

Unfortunately the treatment adopted was injudicious, the quantity of food allowed him being much too large; yet, for the first few days, he appeared to improve, regaining flesh and strength, and acquiring firmness and even cheerfulness of mind; but on the night of the fifth day he was sleepless and restless; on the morning of the sixth, he began to lose his recollection, and before midnight he was quite frantic and unmanageable; at the same time his pulse was increased in frequency, with considerable heat of the skin, and tremors. During the following day he continued raving, and talking very incoherently, as he had done during the preceding night. He remained nearly in the same state, scarcely ever sleeping, and taking very little nourishment, his pulse becoming daily smaller and feebler, and beating at length 120 strokes in a minute, and his emaciation still increasing, until the eleventh day from the period that he began to take food and medicine, and the seventy-second from the commencement of his abstinence, on which day he died, quite exhausted.

There is no authentic case on record in which the duration of the abstinence was as long as this, and both these cases taken together, afford an excellent history of the disorder of the functions, and the exhaustion of the powers of life on the total and continued abstraction of food. The mind in the first case was naturally firm and strong; in the second it was supported by an enthusiasm amounting to insanity. When the mind is feeble, and especially when it is under the influence of fear, anxiety, despondency, or any other depressing cause, the duration of life is greatly abridged. It is instructive to observe the absence of severe suffering from hunger and thirst; the absence of all acrimony of the fluids; the absence of all violence and turbulence of mind until delirium set in, the precursor of death.

From the powerful influence of abstinence on the system, it is obviously capable of becoming a most energetic remedy in various diseases. When the mass of the fluids and solids of the body is too abundant, abstinence is capable of reducing them to almost any extent that can be required; and if the abstinence be judiciously commenced and conducted, not only is it unattended with any diminution of the strength or injury to the health, but it contributes to the improvement of both. Numerous instances are on record which place this fact beyond question. The case of Cornaro the Venetian nobleman, and that of the Essex miller, which afford evidence of this more complete than it would be easy to invent, are universally known. The body, whatever be its bulk or weight, provided the health be in other respects sound, may be reduced to almost any degree of thinness, and kept at that point by an appropriate regulation of diet and exercise. The physician, at his pleasure, can make no one fat, but he can make any one as thin as he chooses, frequently improving at the same time the health and vigour both of body and mind. Seldom is he called upon to put this art into practice, and seldomer than he ought does he insist upon carrying it into practice; but it is something to know that the resources of his art place this in his power.

In all acute diseases, such as the various forms of fever and inflammation, abstinence is a most powerful remedy, not only because the abstraction of nutriment diminishes the mass of the fluids and solids (since the process of absorption goes on though the supply of new matter is stopped), but also because it withdraws one of the main stimulants of the system, and consequently subdues the increased actions which accompany, and which for the most part constitute, acute diseases.

In some chronic maladies, especially in that large class which depend on what is termed plethora, that is, too great a quantity of solids and fluids, particularly in the plethoric state of the blood-vessels of the brain, predisposing to and producing apoplexy, in some morbid affections of the stomach itself, in some derangements of the liver, and in several diseases of the heart, abstinence is an invaluable remedy. In other chronic diseases it is injurious, as in diseases of debility, in diseases which depend on irritation in contradistinction to those which depend on inflammation, and in various nervous maladies.

Abstinence is not equally borne by all persons, nor at all times by the same person. By the corpulent and plethoric it may be endured longer, and carried farther, than by the thin and the spare; in the middle or mature age, it is less injurious than in infancy, youth, or extreme old age. A degree and duration of it, which are highly beneficial in a fever or an inflammation, would be fatal in the state of health.

It is curious, and it is highly important to bear in mind, that abstinence and excess produce symptoms so nearly alike, that it often requires the utmost care and sagacity on the part of the physician to distinguish the one case from the other; and as the one requires opposite remedies from the other, a mistake may be fatal, and must be injurious. A man, addicted to drunkenness, was cast into prison for theft, and reduced, at once, to a diet of bread and water. After the first week, a disorder of the intellectual faculties took place; his countenance became pale and expressive of languor, his flesh wasted, and his strength declined; his nights were sleepless; shortly afterwards there was delirium, which was mild at first, but subsequently furious. These symptoms might have been easily mistaken for those which denote inflammation of the brain; but the true nature of the affection was discriminated, and brandy was administered. Immediately the affection of the brain disappeared, and the flesh and strength returned.

Some time ago an alarming epidemic broke out in the Milbank Penitentiary, London. The prisoners confined in this prison were suddenly put upon a diet, from which animal food was almost entirely excluded. An ox's head, the meat of which weighs eight pounds, was made into soup for one hundred people, which allows one ounce and a quarter of meat to each person. The prisoners were at the same time subjected to a low degree of temperature, to considerable exertion, and were confined within the walls of a prison, situated in the midst of a marsh, which is below the level of the adjoining river. The consequences were, first, loss of colour, of flesh, and of strength; next, this simple debility of constitution was succeeded by various forms of disease—scurvy, dysentery, diarrhœa, low fever; and, lastly, affections of the brain and nervous system—namely, headache, vertigo, delirium, convulsions, apoplexy, and even mania. When bleeding was tried, the patients fainted after losing five, four, or even fewer ounces of blood. Abstinence will sometimes produce a train of symptoms exactly similar to those of the disease which it is employed to remove. Persistence in the abstinence will aggravate the malady, which will baffle every mode of treatment as long as the abstinence is persevered in; but which will disappear with surprising rapidity on the administration of a generous diet. This is especially the case with those affections of simple irritation which assume the appearance of inflammation, and which are attended with headache, noise in the ears, giddiness, restlessness, sleeplessness, and delirium. A professional man was seized with fever; rigid abstinence was enforced, not only during the continuance of the fever, but also during the stage of convalescence. Delirium, which had been present in the height of the fever, recurred in the convalescence. A physician of eminence in maniacal cases was consulted, who recommended him to be removed to a private asylum. Before this advice was carried into effect, another physician saw him: a different treatment and regimen, with a gradual increase of nourishment, were adopted; the patient was well in a few days, and within a fortnight returned to his professional avocations.

It is the common belief that abstinence is conducive to longevity, and many stories are on record which are conceived to establish the truth of this opinion. It is stated, for example, that the primitive Christians of the east, who retired from persecution into the deserts of Arabia and Egypt, lived healthfully and cheerfully on twelve ounces of bread per day, with mere water; that, with this diet, St. Anthony lived 105 years; James the Hermit, 104; Arsenius, tutor of the Emperor Arcadius, 120; St. Epiphanius, 115; Simeon the Stylite, 112; and Romauld, 120: to which are added many others. But we should remark that the evidence for these instances of longevity is not very satisfactory. [FOOD, in NAT. HIST. DIV.]

ABSTRACT. [VENDORS AND PURCHASERS.]

ABSTRACTION is an act of the mind, by which it considers a certain attribute of an object, or several objects, by itself, and without regarding any other attributes which the object or objects may happen to possess. Thus, if we see ink, pitch, ebony, and a negro, we see that these objects have in common the attribute of blackness; and this quality we can in thought *draw off* or *abstract* from the various other attributes which they respectively possess; and consider it separately and independently of anything else. In like manner we can consider any attribute of a single object, such as of the sun or moon, without attending to its other attributes; thus we may contemplate the magnitude of the sun without attending to its heat, light, &c.; so we may contemplate the light of the moon, without attending to its magnitude, the inequalities of its surface, &c. All names of classes, inasmuch as the individual members can never be identical, are formed by a process of abstraction. Thus, when we think of a ship or a house, we pay no attention to the materials, colour, shape, size, construction, convenience, or beauty of the ship or house, but we give the one name to any dwelling of man built by regular artificers, and the other to any vessel with a deck and masts made to sail on the sea. Any object which possesses these attributes we call a ship or a house; though there cannot be any ship or house which possesses *only* those attributes, and is not also of a certain colour, size, shape, &c.; but these incidental qualities we leave out of our consideration in referring any object to the class of houses or ships.

From these remarks it is evident that abstraction, being a merely arbitrary act of the mind, by which a certain attribute is considered apart from any other attributes with which it may happen to be associated, does not represent to us images or notions to which there is anything corresponding in the nature of things; there is nowhere an abstract man or tree which has no colour, dimensions, or other incidents not entering into the abstract notion signified by those general terms. Whenever we recognise in any object those peculiarities which we consider as characteristic of a certain class, we refer it to that class, without taking any heed of the *other* attributes with which they may happen to be combined. Thus, if in some unexplored part of the world there should be discovered a race of animals resembling some known variety of the human race in every particular except the colour of the skin or the hair, they would be doubtless called men, although there is no such thing as an abstract man whose skin or hair is devoid of colour.

The circumstance of there not being any sensible object, or any conception of our mind, which we can image to ourselves without its attributes, has given rise to considerable perplexity on the subject of abstraction. For instance, when we think of a horse, we represent to ourselves an animal of certain colour, shape, and size; though we should equally give the name of horse to an animal of different colour, shape, and size. So, when we think of a plane triangle, although a triangle is any plane figure bounded by three straight lines, yet we cannot help representing to ourselves a triangle which is either right-angled, or acute-angled, or obtuse-angled, or equilateral or scalene. The truth is, that the process by which the mind abstracts is, that it conceives or represents to itself the object of thought as an individual of its class, together with certain particular attributes which must belong to all individuals; and it considers apart from the rest only that attribute which is required for the matter in hand. Thus, if it is a question whether a newly-discovered skeleton is that of an animal belonging to the class of elephants or of deer, the comparative anatomist calls to his mind an elephant or deer, such as actually exists, but *considers* only the structure of his bones; and, if there is a close agreement in this respect, he pronounces the skeleton to have belonged to one of those classes. So, likewise, when a mathematician, by means of a figure described on paper, proves that the square of the hypotenuse equals the sum of the squares of the other sides of a right-angled triangle, although the image in his mind is that of a triangle of a definite size, yet he considers only the relation of the sides and angles, without paying any attention to the length of the lines.

This process, by which the mind *generalises* a particular notion, by considering only a part of it, might be illustrated by many examples of changes in the meaning of words. Thus, there stood formerly on the bank of the Thames, in London, a palace called Bridewell; this, in the reign of Elizabeth, was converted into a penitentiary, or prison for hard labour; whence the term *bridewell* has been extended, and is now sometimes used as a general name for such penitentiaries. So the name *palace* has been extended to all sumptuous houses, having originally been confined to that on the *Palatine* hill, at Rome. It has been remarked that, although brute animals have, like men, the faculty of reasoning or drawing conclusions from premises, yet they have not, like men, the faculty of abstraction. Nevertheless, it is plain that some animals go through a process of which the effects exactly correspond with that of abstraction in men; for example, they can count, and are aware of the recurrence of certain numbers; and a dog who has once been beaten with a stick, or pelted with a stone, will run away from all sticks or stones, of whatsoever size, shape, or colour. That they cannot found, on abstraction, the admirable gift of language, the most important distinction between men and beasts, is owing apparently not to the absence of the power of forming general notions, nor yet to the inability of making articulate sounds, as we may perceive in the instance of the parrot. [NOMINALISTS.]

ABSURDUM, REDUCTIO AD, is that species of argument which proves, not the thing asserted, but the absurdity of everything which contradicts it. It is much used in geometry, in order to demonstrate the converse of a proposition already proved. One of two things must be true; either the proposition asserted, or something which contradicts it. If the opposing party deny the proposition, he must affirm that which is contradictory. Let his counter-proposition be taken for granted; then, if by the legitimate use of it some absurdity can be deduced, it is evident that his contradiction is wrong, and the original proposition right. As an instance of this method of proceeding, let us suppose it has been proved, and is not denied, that whenever A is B then C is D. We may then affirm that when C is not D, A is not B. For if A were B, C would be D; but C is not D, therefore A is not B. The full form of the *Reductio ad Absurdum*, in this case, is as follows:—You grant that if A were B, C would be D; but you refuse to admit the consequence that, when C is not D, A is not B; that is, you say that C may not be D, and yet A may be B. Let this, then, be as you say, that is, let C not be D, and yet let A be B. But in supposing that A is B, the admitted proposition obliges you to say that C is D. But you have supposed that C is not D: you therefore say at the same time that C is D, and that C is not D, which is absurd. Consequently, if it be true that whenever A is B then C is D, it follows that when C is not D, A is not B.

The *Reductio ad Absurdum* has been objected to as not equally conclusive with direct demonstration. For this there is no foundation; though it must be admitted that direct demonstrations are more pleasing and more elegant. But it is obvious that, if everything which contradicts a proposition be false, the proposition itself must be true. The student of logic must distinguish between that which is only *contradictory*, and that which is *contrary* to a proposition. Thus, to the proposition that "all squares are equal," it is contradictory that "*some* squares are not equal," and contrary, that "*no* squares are equal." The contrary is the most complete contradictory, and affirms that the proposition is true in no one instance. It is not correct to say that, if a proposition be false, its contrary is true; for example, it is false that all squares are equal, and equally false that no squares are equal. But of a proposition and its contradictory one must be true; thus either all squares are equal or some squares are not equal. Hence, whatever disproves a proposition proves something contradictory, and whatever disproves everything contradictory proves the proposition. The *Reductio ad Absurdum* is, therefore, as conclusive as direct demonstration.

The *Reductio ad Absurdum*, in Euclid, is wholly unnecessary to all who can see that *contra-positive* propositions are identically the same. The following forms are contra-positive:

Every A is B
Every not-B is not-A.

Thus (Euclid I. 4) two sides equal to two sides understood, proves that equal angles give equal areas: that is, unequal areas give unequal angles. He then has to prove I. 6, which he does by *Reductio ad Absurdum*. His form is, equal base angles give equal opposite sides: its equivalent contra-positive is, unequal sides give unequal opposite angles. From the unequal sides it may immediately be shown, as in Euclid, that two triangles having two pairs of sides equal, each to each, have unequal areas, and therefore unequal angles. Thus it is shown that the angles opposite unequal sides are unequal: which is but saying that the sides opposite equal angles are equal. Had logic been cultivated concurrently with geometry, the *Reductio ad Absurdum* would long ago have disappeared, in nearly all the cases in which it is now used.

ABUTMENT, in building, is that which receives the end of, and gives support to, anything having a tendency to thrust outwards in a horizontal direction. The piers against which an arch that is less than a semi-circle rests are abutments; while the supports of an arch of any other figure, which springs at right angles to the horizon, are imposts. The piers of the arches of Southwark and Vauxhall bridges are abutments or abutment-piers; whereas those of London, Blackfriars, and Waterloo bridges, and of the old Westminster bridge, are imposts or impost-piers. Nevertheless, the piers at the extremities of a bridge, of whatever form its arch or arches may be, are always termed its abutments; that is, abutments of the bridge itself.

ABUTMENT, in machinery, is a term applied to a fixed point from which resistance or re-action is obtained. In an ordinary steam-engine, for example, each end of the cylinder acts alternately as an abutment. The steam, being unable to expand itself in the direction of the fixed obstacle, that is, the end of the cylinder, expends the whole of its elastic force in the opposite direction, against the movable obstacle or piston. In like manner the breech of a gun forms an abutment for the expansive force of the ignited powder; although in this case, the abutment not being absolutely a fixed point, its recoil occasions some loss of power. Even a rotatory steam-engine, with a continuous circular action, must have an abutment to render the force of the steam effective. Springs, whether used to impel machinery, as in the case of a watch, or to measure or control force, as in the various contrivances noticed under SPRING-BALANCE, must have their abutments or points of resistance; as also must all mechanical combinations in which power is transmitted by means of screws, of which it is sufficient to cite as an example the nut in the fixed head of an ordinary screw-press. In all these cases an analogy may be traced with the use of the term abutment in architecture. With a similar meaning the name is applied in carpentry to a joint in which two pieces of timber meet so that the fibres of one piece run in a direction oblique or perpendicular to the joint, and those of the other parallel with it.

ABUTTALS, from the French *abutter*, to limit or bound, are the buttings and boundings of lands to the east, west, north, and south, showing by what other lands, highways, hedges, rivers, &c., such lands are in those several directions bounded.

The boundaries and abuttals of corporation and church lands, and of parishes, are usually preserved by an annual procession.

ABYSSINIAN CHRISTIANS. The discovery of a body of Christians in so remote a country excited, in no small degree, the attention of Europe in the 15th century, which was again revived by Salt's last mission, in 1810. From the 'Tareek Negushti,' or 'Chronicle of the Abyssinian Kings,' combined with the evidence of the ecclesiastical writers, we learn that Christianity was introduced into Abyssinia in the time of Constantine, by Frumentius, or Fremonatos, as the chronicles call him. Frumentius, after residing some years in the country, was raised by Athanasius the patriarch of Alexandria, to the dignity of bishop. He arrived in Abyssinia, perhaps about the year A.D. 330, and probably in the reign of the King Aizanas, whose name still exists in the inscription of Axum. It is, however, not certain to which king of the Abyssinian chronicles we ought to apply the names of Aizanas and his brother Saizanas, both of which occur in the inscription, and also in a letter of the Emperor Constantine, addressed to them A.D. 356. When the Greek merchant Cosmas visited Abyssinia, A.D. 525, it was completely a Christian country, and well provided both with ministers and churches. Of the Abyssinian churches, which probably belong to the earlier periods of their conversion, or at least are eight or nine hundred years old, there are still some remains. The most remarkable is Abuhasubha, hewn out of the solid rock, which at this place is soft and easily worked. The Portuguese, Alvariz, describes ten such churches as these, of which he has given a plan, and one of them is probably the same as that which Mr. Pearce visited at Jummada Mariam. (Salt, p. 302.) The great church at Axum is comparatively modern, though parts of it, such as the steps, clearly belong to a prior edifice. Mr. Salt describes the well-built remains of a church or monastery near Yahee, which he assigns to the 6th century of the Christian era.

The monastic, and also the solitary life, spread into Abyssinia from the deserts of the Thebais, and when the Portuguese Jesuits entered the country they found it full of such devotees; many of them seemed, however, to be monks only as far as celibacy was concerned, for they cultivated the ground and lived in villages.

With the Christian religion, the Abyssinians received the Holy Scriptures, which they now possess in the ancient Ethiopic version, made, according to Ludolf, from the Greek Septuagint, though nothing is known of the date of this version. As to the New Testament (says Ludolf), no entire copy has been yet brought to Europe. Mr. Bruce brought with him from Abyssinia a complete copy of the Scriptures in the Ethiopic language, and also a set of the Abyssinian Chronicles. The Abyssinians divide the Scriptures, which they have entire, differently from what we do, making four principal parts of the Old Testament, and mixing what we call the Canonical with the Apocryphal books. The New Testament is also divided into four parts, to which they add the Book of Revelation as a supplement. The old written language is of the Semitic stock, and is written from left to right, but the language is not now spoken; there are two languages now in use, the Tigré and the Amharic. For other information respecting the Abyssinian liturgies, and the religious opinions of the Abyssinians, we refer to Ludolf, Book iii. chaps. 4, 5. Ludolf denies the existence of the Book of Enoch, because he had only seen a spurious copy. A knave who got possession of an Ethiopic book, wrote the name of Enoch upon it, and sold it to Peiresc for a considerable sum of money, and this was the book that Ludolf saw. Bruce brought home three copies of the book of Enoch; one of which he gave to the Bodleian Library at Oxford. This book was originally written in Greek, but the original is lost—all but one large fragment. In the epistle of Jude reference is made to the prophecies of Enoch; and Mr. Bruce says, "the quotation is word for word the same in the second chapter of the book." This, however, will not prove the genuineness of the prophecies of Enoch, as Mr. Bruce has very well argued. An English translation of the book of Enoch was published by Dr. Lawrence, Oxford, 8vo. 1822.

The High Priest (or sole bishop) of Abyssinia is called *Abuna*, which signifies Our Father; and as Frumentius, the first bishop, received his appointment from the Patriarch of Alexandria, this dignitary has, probably, always been a foreigner. The king is the head of the Church. Polygamy, though not allowed by the ecclesiastical canon, is common enough in practice; and Mr. Salt mentions an instance of one gentleman who had five wives at once. The king, of course, marries as many as he pleases: the clergy, also, who are not monks, may marry, but only once. A second marriage renders them unworthy of their sacred office, according to the ancient canons. Circumcision, according to Bruce, is practised in Abyssinia, and baptism of infants and agapæ or love-feasts have been in use ever since the introduction of Christianity. The creed of the Abyssinian Church is what is called the Monophyiste; *i. e.*, admitting the divinity of our Saviour, but acknowledging in him only one nature.

It would appear, from what we know of the Abyssinian Church, that its priests, at present, are not well informed, nor are the people in general well acquainted with the principles of the Christian religion, though they may be Christians in name; yet some of their ceremonies are conducted with great decency, and very much resemble those of the Church of England. When Salt was at Chelicut, Lent was strictly observed for fifty-two days, and no flesh was eaten during this period, though fish and various dishes were always plentiful on the table: the people always fasted till sunset. A feast followed this severe and protracted fast, in which they all seemed anxious to make up for lost time, by over eating and drinking. The Sacrament is also administered in Abyssinia, in a very decorous manner; and red wine made of a grape which is common in some parts of the country, is used on the occasion. Formerly (says Mr. Salt) if a man married more than one wife, he was excluded from participating in this rite, but wealth and power have induced the Church to relax its severity in this respect. Marriage itself in Tigré, appears a mere civil institution: the woman keeps her name, and the parties can separate whenever they agree to do so. In this case the woman has her dowry back, which is not forfeited unless she is manifestly guilty of adultery. The higher classes are subject to no rule, but what may be considered as imposed by the relatives of the male and female. The priests are forbidden to marry after ordination. The Abyssinians bury their dead immediately after washing and fumigating the body with incense: while the bearers are putting it in the ground, the priests recite a form of prayer. Other strange ceremonies that follow are described by Salt.

(Ludolf's *History of Ethiopia*; Bruce, vol. ii. p. 422; Salt's *Abyssinia*; Rüppell; Gobat, *Journal of a Three Years' Residence in Abyssinia*; and Professor Lee's *Brief History of the Church of Abyssinia*, prefixed to that work.)

ACADEMY. A house and garden in one of the suburbs of Athens, inclosed by a wall, and having the grounds laid out in walks shaded by trees, was the original Academy. It is commonly stated to have been so called from its original possessor Academus, or Ecademus, who is said to have established here a school of gymnastic exercises. Other etymologies of the term, however, have also been given. About the middle of the 5th century before the commencement of our era, the groves of Academus fell into the possession of Cimon, the Athenian general; and it was he who first adorned the place with statues and fountains, and added other improvements, so as to convert it into a retreat uniting to the charms of natural scenery many of the luxuries of art. At his death he left the garden to the public; and it became a favourite resort of the lovers of philosophy and solitary meditation. Hither Socrates was wont occasionally to repair to converse with his disciples. But it was his illustrious pupil, Plato, who first gave celebrity to the Academy as the seat of philosophy, by establishing here the school over which he presided for nearly half a century. Hence the Platonic philosophy is frequently called Academism, or the philosophy of the Academy; and its followers, Academics, or Academists. Plato died about the year 348 before the Christian era. About the year B.C. 296, one of his successors, Arcesilaus, introduced certain changes into the original doctrines of the school; and he is on this account considered the founder of a second, or Middle, as distinguished from the Old academy. There was also in this sense a third academy, called the New, of which the founder was Carneades, who flourished about a century after Arcesilaus. Some writers even reckon a fourth Platonic academy, founded soon after the time of Carneades, by Philo (not the celebrated Platonic Jew), and Charmidas or Charmadas; and a fifth, designated the Antiochian, from its founder, Antiochus, who had been a disciple of Philo. With regard to the academy of Plato, we may further notice that it was situated in the suburb, lying N.W. of Athens, called Ceramicus, that is, literally, the Place of Tiles; and it has been remarked, as a curious coincidence, that the principal public garden of that city should thus have apparently had the same origin with the Tuileries of the modern capital of France, a name which also indicates that the site was anciently that of a tile-work. Cicero had a country seat on the Neapolitan coast, to which, as one of his favourite retreats for philosophical study and converse, he gave, in memory of the famous Athenian school, the name of Academia. It was here he wrote his Academic Questions. Its remains are still pointed out near Pozzuoli, under the name of the Bagni de' Tritoli.

After the restoration of letters in the 15th century, the term Academy was revived in Italy, but with a signification somewhat different from what it had borne in ancient times. It was used to imply, not a school in which philosophy was taught by a master to his pupils, but an association of individuals formed for the cultivation of learning and science, and usually constituted and endowed by the head of the state in which it was established. What was now called an academy, in fact, more nearly resembled what was anciently denominated a Museum,—the name given, for example, to the famous association of the learned, founded by the first Ptolemy, at Alexandria, which so long subsisted in that city. The Emperor Charlemagne is also recorded, towards the close of the 8th century, to have established in his palace at Paris a society of this description. Charlemagne was also the founder of the University of Paris, and several other schools and seminaries of instruction; but although the Greek term Academia has often, at least in more recent times, been applied to such institutions, they are altogether distinct in their nature from what is properly called an academy.

On the other hand, many of those associations of the learned, which, in all material respects, resemble the academies that arose in Italy with the revival of letters, are, nevertheless, not known by that name. They are called not academies, but Societies, Associations, Museums, Lyceums, Athenæums, Institutes, &c. Of such associations, British and foreign, which have issued, and many of which continue to issue their printed Transactions, Journals, or various works, the Catalogue of the British Museum contains a list of about 1250. Among the more celebrated, and one of the earliest, was the Academy 'della Crusca,' that is, literally, *of the bran*, or *chaff*, in allusion to the object of its institution, the purifying of the national tongue, and the sifting, as it were, of its flour from the bran. It was established at Florence in 1582, principally by the exertions of the poet Antonio Francesco Grazzini, who is much celebrated for the purity of his style. The Dictionary of the Academia della Crusca, first published under the title of 'Vocabolario degli Academici della Crusca,' at Venice, in 1 vol. fol., in 1612; but augmented, in 1729-1738, to 6 vols. fol., is considered as the standard authority for the Italian language; and the writers from whose works it has been collected, or whom it recognises as classics, such as Boccaccio, Machiavel, &c., are hence frequently denominated *Autori Cruscanti*. The Academia della Crusca is now incorporated with two still older societies, the Academia degli Apatici (or *Academy of the Impartials*), and the Academia Fiorentina, originally the Academia degli Umidi, founded in 1549 by Cosmo I. The united institutions bear the name of the Royal Florentine Academy. Another very famous old Florentine academy is that entitled Del Cimento, that is, the *Academy of Experiment*. It was instituted for the cultivation of physical science, by the Cardinal Leopold de' Medici, brother of the Grand Duke Ferdinand II., in 1657. Among its first members were Borelli, Viviani, &c. A collection of experiments on the pressure of the air, the compressibility of water, on heat, sound, projectiles, light, and other subjects belonging to natural philosophy, was published in Italian by the Academy del Cimento in 1667, of which Muschenbroeck afterwards gave to the world a Latin translation, with valuable notes. Many of the Italian academies are remarkable for the fantastic names by which they are designated; and in 1725 there were nearly 600 of them. The Royal Academy of Sciences and Belles Lettres of Naples was founded in 1779; it has published its Transactions, which contain many valuable papers on mathematical subjects, since 1788. The Herculanean Academy of Naples, was founded in 1755; the first volume of its Transactions appeared in 1775, under the title of 'Antichità di Ercolano,' and it has been followed by several others. The Academy of Etruscan Antiquities at Cortona, founded in 1726, and that at Florence, founded in 1807, have both published valuable Transactions. There are also academies at Padua, Milan, Siena, Verona, and Genoa, by all of which some volumes of Transactions have been printed. The Academy of Bologna was originally founded in 1690, by the afterwards distinguished astronomer Eustachio Manfredi, then only sixteen. The associates called their institution the Academia degli Inquieti, and took for their motto the words *Mens agitat*. In 1714 this academy was united to the University or Institute of Bologna, since which event it has been called the Academy of the Institute, or the Clementine Academy (from Clement XI., the then Pope). Its Transactions have been published under the title of 'Commentarii,' since 1731. To this list we may add the Royal Academy of Turin, in Piedmont, which was originally a private association founded about the middle of the last century, by the young Lagrange, then, although not yet twenty years of age, holding the office of Professor of Mathematics in the Royal Artillery School of that city. The first volume of its Transactions was published in Latin, in 1759, and surprised the scientific world by some papers of great originality, to which the name of Lagrange was appended. The Turin Transactions, which continued for some years to be enriched by the contributions of this eminent mathematician, were published in Latin, till 1784, since which time they have appeared in French.

The Académie Française was instituted in 1635 by Cardinal Richelieu, for an object of the same nature with that proposed by the Academia della Crusca,—the purification, regulation, and general improvement of the national tongue. This society, in imitation of its Italian model, published in 1694 the first edition of a French Dictionary, known by the name of the Dictionary of the Academy, to which it afterwards made many additions in successive reprints. This work however has scarcely perhaps attained the same authority with that of the Della Cruscan academicians; partly owing, no doubt, to the comparative immaturity of the French language when it was thus attempted to restrain its further growth. The original number of the members of the Académie Française was forty, from whom were elected a director and a chancellor every three months, as well as a secretary, who held his office for life. This constitution it continued to retain till the year 1793, when it was abolished, with most of the other establishments which had subsisted under the ancient government. Two years after it was restored as part of the Institute. The next of the French academies, in point of antiquity, is the 'Académie Royale des Inscriptions et Belles Lettres.' It was established in 1663, in the reign of Louis XIV., by Colbert, and consisted originally of a few members selected from the Académie Française. In 1701 this academy was placed, by an edict of the king, upon a new and more extended foundation; and from this date it published every year a volume of memoirs, many of great value, till it was suppressed at the Revolution. It consisted, at the period of its suppression, of ten honorary members, ten pensionaries, and twenty associates, exclusive of several corresponding members. The 'Académie Royale des Sciences' was originally established by Colbert in 1666, but was entirely remodelled in 1699. By the new constitution its researches were confined to the department of the physical sciences. The Académie des Sciences first began to publish its Transactions in 1666, and from 1699 a volume appeared regularly every year till the academy was suppressed in 1793. These three academies, together with the Académie Royale de Peinture et de Sculpture, which had been rather a school of painting than an association of cultivators of the art, were restored by the Directory in 1795, and united into what was called the National Institute. The French Institute has, since its establishment, ranked as the very first of the scientific associations of Europe, the most illustrious of whose philosophers have usually been comprehended in the list of its members.

The Royal Academy of Spain, founded at Madrid, in 1714, principally by the exertions of the Duke of Escalona, was constituted on the model of the Academia della Crusca and the Académie Française, and has for its object the improvement and purification of the Spanish language, of which it has published a Dictionary, under the title of

'Diccionario de la Lengua Castellana,' six vols. fol., 1726-1739. The Royal Academy of Spanish History was commenced as a private association at Madrid in 1730, but was taken under the royal protection, and incorporated by Philip V. in 1738. It consists of twenty-four members. The first volume of its Transactions was published in 1796, under the title of 'Memorias de la Real Academia de la Historia.' It has also printed some ancient manuscripts, and given new editions of some historical works. There are also an Academy of History and Geography at Valladolid, and a Literary Academy at Seville, both founded in 1753.

The principal Portuguese academy is the Academy of Science, Agriculture, Arts, Commerce, and general Economy, founded by Queen Maria in 1779. It has published several volumes of Transactions in different sets. There is also a Geographical Academy at Lisbon, established in 1799.

Of Austrian Academies, the most ancient is the 'Academia Naturæ Curiosorum,' established at Vienna in 1652. In 1687, during the reign of the Emperor Leopold I., it assumed the name of the Academia Cæsareo-Leopoldina. Its Transactions were at first published in separate treatises, but since 1684 they have appeared in volumes, under the title of 'Ephemerides et Acta Academiæ Cæsareæ Naturæ Curiosorum.' A history of this academy was published by Büchner, Halle, in 1756. The Academy of Arts and Sciences of Vienna was founded in 1705. In 1754 was established in the same city an Academy for the cultivation of the Oriental Languages.

The Royal Academy of Science and Belles Lettres of Berlin has long been one of the most eminent among the learned societies of Europe. It was established in 1700, by Frederick I., who appointed the celebrated Leibnitz its first president. The first volume of its Transactions appeared in 1710, under the title of 'Miscellanea Berolinensia,' and other volumes followed at intervals of three or four years, till the accession of Frederick the Great in 1740, who, in 1744, took it under his special protection, and proceeded to give it a new organisation, with the view of extending its usefulness, and raising it to a higher rank than it had hitherto enjoyed. A history of this academy was published in 1752. In 1754, was established by the Elector of Mainz, the Electoral Academy at Erfurt, for the promotion of the useful sciences. Its Transactions were originally published in Latin, under the title of 'Acta Academiæ Electoralis Moguntinæ Scientiarum Utilium;' but they have of late appeared in German.

Of other German Academies the principal are—the Academy of Sciences, otherwise called the Royal Society, of Göttingen, established in 1733; the Electoral Academy of Science and Bavarian History at Munich, first established in 1760, but greatly enlarged since the erection of Bavaria into a kingdom, and which has published its Transactions, since 1763, in German, under the title of 'Abhandlungen der Baierischen Akademie;' that of Mannheim, founded in 1755, by the Elector Charles Theodore, and now divided into three classes—historical, physical, and meteorological; the Transactions of the two former of which have been published, under the title of 'Acta Academiæ Theodoro-Palatinæ'—those of the last, under that of 'Ephemerides Societatis Meteorologicæ Palatinæ;' and the Academy of Suabian History, established at Tübingen, in Würtemberg.

The Royal Academy of Sciences, of Stockholm, was originally a private association, founded by Linnæus, and a few of his friends, in 1739, and was not incorporated by the Crown till two years afterwards. Its Transactions appear in quarterly parts, which form an octavo volume a year. The first forty volumes, from 1739 to 1779, are called the 'Old Transactions;' those which have appeared since, the 'New.' They are written in Swedish, but have also been translated into German. Stockholm also possesses an Academy of the Belles Lettres, founded in 1753; and an institution denominated the Literary Academy of Sweden, founded in 1786. The object of the latter is the cultivation and improvement of the national language. There is an Academy for the investigation of Northern Antiquities, at Upsal, which has published some valuable volumes of Memoirs. The Royal Academy of Sciences of Copenhagen was founded by the Count of Holstein in 1742, and incorporated the following year. Its Transactions appear in Danish; but they have been partly translated into Latin.

The Imperial Academy of St. Petersburg, like most of the valuable institutions of Russia, originated in the bold and contriving mind of Peter the Great. That monarch however did not live to carry into effect the scheme which he had arranged, and which is said to have been suggested to him by his inspection of the academies of France, when in that country in 1717, and to have been matured by consultations with Christian Wolff and Leibnitz. But immediately after his death, in 1725, his successor, Catherine I., proceeded to execute the intentions of her deceased husband; and the Academy was forthwith established, and held its first sitting in December of that year. Some of the most distinguished foreign mathematicians and philosophers of the day were wisely selected by the empress to grace the new foundation, and induced by liberal salaries to accept places in it under the title of professors. Among them were Wolff, Nicolas and Daniel Bernoulli, Bulfinger, &c. In its earlier days this institution underwent various fluctuations in reputation and efficiency, according as it happened to be patronised or neglected by the reigning sovereign; but since the accession, in 1741, of the Empress Elizabeth, who placed it upon a broader and more independent basis, it has generally maintained a high character. Its annual revenue is considerable; and one important service which it has thus been enabled to render, has been the exploration of various portions of the Russian empire, by means of the travellers Pallas, Stolberg, Klaproth, and others, whom it has sent out for that purpose. Its Transactions, down to the year 1747 inclusive, forming 14 volumes, are in Latin, and are entitled 'Commentarii Academiæ Scientiæ Imperialis Petropolitanæ.' Twenty volumes more, down to 1777, likewise in Latin, are entitled 'Novi Commentarii.' Since 1777 they take the name of 'Acta,' and are partly in Latin and partly in French. Of the whole number of mathematical papers which appeared in these Transactions down to the year 1783, in which he died, the celebrated Euler is computed to have written fully one half; and he left behind him about a hundred additional memoirs, which have appeared in the volumes printed since that period. These papers of Euler's contributed, more than any other publications of the time, to the simplification and improvement of the modern analysis. The Imperial Academy possesses a library of some extent, which contains a considerable number of oriental manuscripts, as well as valuable collections of medals and of specimens of natural history. In 1783, an institution, on the model of the Académie Française, having for its object the improvement of the Russian language, was founded at St. Petersburg, and was soon after united with the Imperial Academy.

Among the other European academies, may be mentioned the Medical Academy of Geneva, founded in 1715; the Académie des Sciences et des Belles Lettres of Brussels, which has published its Transactions, under the title of 'Mémoires,' since the year 1777; and the institution of the same name at Flushing, whose Transactions have also appeared. In the British dominions there are no associations for the cultivation of science or learning, which have this name, except the Royal Irish Academy, founded in 1782, and which has published its Transactions since 1787. In the United States of North America, as in England, such institutions are, for the most part, called *Societies*, but a few are styled Academies, such as those at Boston and Philadelphia, and have published their Transactions.

Academy is also the name usually given, both in this country and on the Continent, to an institution established for the cultivation and promotion of the fine arts, that is, of painting, sculpture, architecture, and music. Such institutions commonly partake both of the character of academies, in the sense already explained, and of schools or colleges, consisting, on the one hand, of an association of amateurs and distinguished proficients, professing to have in view the diffusion of a taste for the arts among the public generally, by publications, exhibitions, or any other means which may be made available for that end; and, on the other, of an establishment of teachers or professors, for the instruction of youth in the practice of some one or more of the branches in question. The latter object is effected by lectures, by prescribed tasks, and by the distribution of prizes and honours. Societies of painters, for the promotion and protection of their art, are of very ancient date. The Royal Academy of London originated in an association of painters, who obtained a charter, in 1765, under the title of the Incorporated Society of Artists of Great Britain. This society, however, was soon after broken up by disputes among its members; and in 1768, the Royal Academy of Arts was incorporated in its stead. It consists of forty artists bearing the title of academicians, of twenty associates, of two academician engravers, of five associate engravers, and of three or four individuals of distinction, under the name of honorary members, but who also hold certain nominal offices. From the academicians are selected the professors of painting, of sculpture, of architecture, and of perspective; and there is also a professor of anatomy, who is commonly a member of the medical profession. Nine of the academicians are likewise appointed annually to officiate in setting the models, and otherwise superintending the progress of the students. The sovereign is the patron of this institution; but its funds are, we believe, entirely derived from the money paid by the public for admission to the exhibition, which takes place every year, in the months of May, June, and July. A branch of the English Royal Academy was established some years ago at Rome. The Edinburgh Royal Academy of Painting was founded in 1754. A similar institution has also been established in Dublin, under the title of the Royal Hibernian Academy. An Academy of Ancient Music was established in London so early as the year 1710; but a disagreement among its members occasioned its dissolution after it had existed above twenty years. Some time after this the Royal Academy of Music was instituted, with Handel at its head, and for ten years, during which the operas of that great composer were performed under its superintendence in the Haymarket Theatre, enjoyed splendid success. But discord here also came at length, to divide and disperse the professors of harmony; and in the year 1729, the institution was broken up. A new Royal Academy of Music, which holds its meetings in Hanover-square, was established in 1822. The French Opera, it may be added, is styled the Académie de Musique.

ACA'NTHUS (in Architecture). The name by which the leaf used in the enrichment of the Corinthian capital is known. It is thus called because of its general resemblance to the leaves of a species of the acanthus plant; or rather because of a pretty traditional story which the Roman author Vitruvius tells of the fancied origin of the Corinthian capital, in which the leaves are said to be imitated from those of the acanthus. The same leaf, however, is commonly used in architectural and sculptural enrichments generally; in the enrichment of modillions, of mouldings, and of vases, as well as of foliated capitals; and we gather from Virgil, that the acanthus was by the ancients also employed as an ornament in embroidery. In the first book of the '*Æneid*,' verse 649, and again at 711, a veil or vest is said to be interwoven or embroidered with the crocus-coloured or saffron acanthus.

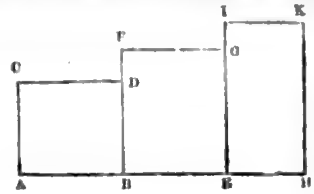
Pliny the elder, in his 'Natural History,' describes the acanthus in such a manner that it can only be recognised in the brank-ursine; and his nephew, in speaking of the successful cultivation of the same plant as an ornament to his garden, leaves little doubt that the brank-ursine is identical with the common architectural and sculptural acanthus. It is stated, however, that the brank-ursine (*Acanthus mollis*) does not grow in Greece, and it has been suggested that the plant from which the Greek architectural ornament was taken was the *Acanthus spinosa*, which grows there, and is still called the ἄκανθα.

This ornament, in the ancient Greek and Roman models, is very characteristic of the styles of architectural enrichment of those nations; in the Roman it is full, and somewhat luxuriant, and in the Greek more restrained, but simple and graceful.

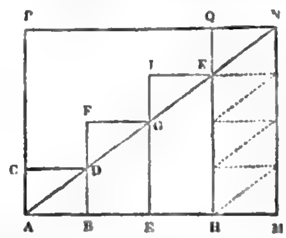
Roman. Greek.

ACCELERATED MOTION, ACCELERATING FORCE, ACCELERATION. When the velocity of a moving body is continually increased, so that the lengths described in successive equal portions of time are greater and greater, the motion is said to be accelerated, which is the same thing as saying that the velocity continually increases. [VELOCITY.] We see instances of this in the fall of a stone to the earth, in the motion of a comet or planet as it approaches the sun, and also in the ebb of the tide. As it is certain that matter, if left to itself, would neither accelerate nor retard any motion impressed upon it, we must look for the cause of acceleration in something external to matter. This cause is called the *accelerating force.* [See INERTIA; FORCE; CAUSE: to the remarks in the last of which articles we particularly refer the reader, both now and whenever the word cause is mentioned.] At present, the only accelerating force which we shall consider is the action of the earth, producing what is called *weight*, when not allowed to produce motion.

It is observed, that when a body falls to the ground from a height above it, the motion is *uniformly* accelerated; that is, whatever velocity it moves with at the end of the first second, it has half as much again at the end of a second and a half; twice as much at the end of two seconds; and so on. At least this is so nearly true, that any small departure from it may be attributed entirely to the resistance of the air, which we know from experience must produce some such effect. And this is the same with every body, whatever may be the substance of which it is composed, as is proved by the well-known experiment of the guinea and the feather, which fall to the bottom of an exhausted receiver in the same time. The velocity thus acquired in one second is called the measure of the accelerating force. On the earth it is about 32 feet 2 inches per second. If we could take the same body to the surface of another planet, and if we found that it there acquired 40 feet of velocity in the first second, we should say that the accelerating force of the earth was to that of the planet in the proportion of $32\frac{1}{6}$ to 40. By saying that the velocity is $32\frac{1}{6}$ feet at the end of the first second, we do not mean that the body falls through $32\frac{1}{6}$ feet in that second, but only that if the cause of acceleration were suddenly to cease at the end of one second, the body would continue moving at that rate. In truth, it falls through only half that length, or $16\frac{1}{12}$, in the first second. It may be proved mathematically, that if a body, setting out from a state of rest, have its velocity uniformly accelerated, it will, at the end of any time, have gone only half the length which it would have gone through had it moved, from the beginning of the time, with the velocity which it has acquired at the end of it. Thus, if a body have been falling from a state of rest during ten seconds (the resistance of the air having been removed), it will then have a velocity of $32\frac{1}{6} \times 10$ or $321\frac{2}{3}$ feet per second. Had it moved through the whole ten seconds with this velocity, it would have passed over $321\frac{2}{3} \times 10$ or $3216\frac{2}{3}$ feet. It really has described only the half, or $1608\frac{1}{3}$ feet. We may give an idea of the way in which this proposition is established, as follows:—The area of a rectangle [RECTANGLE]—that is, the number of *square feet* it contains, is found by multiplying together the numbers of *linear feet* in the sides. Thus, if A B be 4 feet, and A C 5 feet, the number of square feet in the area is 4×5, or 20. Again, the number of feet described by a body moving with a uniform velocity, for a certain number of seconds, is found by multiplying the number of seconds by the number of feet per second or the velocity. If, then, A B contain as many feet as there are seconds, and A C as many feet as the body moves through per second; so many feet as the body describes in its motion, so many square feet will there be in A B D C. That is, if we let A B *represent* the time of motion, and A C the velocity, the area A B D C will *represent* the length described in the time A B, with the velocity A C.



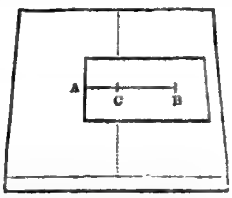
Not that A B D C is the length described, or A B the time of describing it; but A B contains a foot for every second of the time, and A B D C contains a square foot for every foot of length described. Similarly, if at the end of the time just considered, the body suddenly receive an accession of velocity D F, making its whole velocity B F per second; and if with this increased velocity it move for a time which contains as many seconds as B E contains feet, the length described in this second portion of time will contain as many feet as B E G F contains square feet; and the whole length described in both portions of time will be represented by the sum of the areas A B D C and B E G F. And similarly for another accession of velocity G I, and an additional time represented by E H. Now, let a body move for the time represented by A M; at the beginning of this time let it be at rest; and by the end let it have acquired the velocity M N: so that had it moved from the beginning with this velocity, it would have described the length represented by A M N P. Instead of supposing the velocity to be perpetually increasing, let us divide the time A M into a number of equal parts—say four, A B, B E, E H, H M—and let one-fourth of the velocity be communicated at



the beginning of each of these times, so that the body sets off from A, with the velocity A C, which continues through the time represented by A B, and causes it to describe the length represented by A B D C. We know from geometry that B D, E G, and H K, are respectively one-fourth, one-half, and three-quarters of M N, which is also evident to the eye, and may be further proved by drawing the figure correctly, which we recommend to such of our readers as do not understand geometry. Hence, G E or B F is the velocity with which the body starts at the end of the time A B; E I at the end of A E; and H Q at the end of A H. Consequently, the whole length described is a foot for every square foot contained in A B D C, E B F G, E I K H, and H Q N M, put together. But this is not a uniformly accelerated velocity, for the body first moves through the time A B, with the velocity A C, and then suddenly receives the accession of velocity D F. But if, instead of dividing A M into four parts, we had divided it into four thousand parts, and supposed the body to receive one four-thousandth part of the velocity M N at the beginning of each of the parts of time, we should be so much nearer the idea of a uniformly accelerated velocity as this, that instead of moving through one-fourth of its time without acquiring more velocity, the body would only have moved one four-thousandth part of the time unaccelerated. And the figure is the same with the exception of there being more rectangles on A M, and of less width. Still nearer should we be to the idea of a perfectly uniform acceleration if we divided A M into four million of parts, and so on. Here we observe—1, that the triangle A N M is the half of A P N M; 2, that the sum of the little rectangles A C D B, B F G E, &c., is always greater than the triangle A N M, by the sum of the little triangles A C D, D F G, &c.; 3, that the sum of the last-named little triangles is only the half of the last rectangle H Q N M, as is evident from the inspection of the dotted part of the figure. But by dividing A M into a sufficient number of parts, we can make the last rectangle H Q N M as small as we please, consequently we can make the sum of the little triangles as small as we please; that is, we can make the sum of the rectangles A C D B, &c., as near as we please to the triangle A N M. But the more parts we divide A M into, the more nearly is the motion of the body uniformly accelerated; that is, the more nearly the motion is uniformly accelerated, the more nearly is A N M the representation of the space described. Hence we must infer (and there are in mathematics accurate methods of demonstrating it), that if the acceleration were *really* uniform, A N M would really have a square foot for every foot of length described by the body; that is, since A N M is half of A P N M, and the latter contains a square foot for every foot of length which *would have been* described if M N *had been* the velocity from the beginning, we must infer that the length described by a uniformly accelerated motion from a state of rest, is half that which would have been described, if the body had had its last velocity from the beginning.

If the body begin with some velocity, instead of being at rest, the space which it would have described from that velocity must be added to that which, by the last rule, it describes by the acceleration. Suppose that it sets out with a velocity of 10 feet per second, and moves for 3 seconds uniformly accelerated in such a manner as to gain 6 feet of velocity per second. Hence it will gain 18 feet of velocity, which, had it had at the beginning, would have moved it through 18×3 or 54 feet of length, and the half of this is 27 feet. This is what it would have described had it had no velocity at the beginning; but it has 10 feet of velocity per second, which, in 3 seconds, would move it through 30 feet. Hence 30 feet and 27 feet, or 57 feet, is the length really moved through in the 3 seconds.

Similarly we can calculate the effects of a uniform *retardation* of velocity. This we can imagine to take place in the following way. While the body moves uniformly from left to right of the paper, let the paper itself move with a uniformly accelerated velocity from right to left of the table. Let the body at the beginning of the motion be at the left edge of the paper, and let that edge of the paper be placed on the middle line of the table. Let the body begin to move on the



paper uniformly 10 inches per second, and let the paper, which at the beginning is at rest, be uniformly accelerated towards the left, so as to acquire 2 inches of velocity in every second. At the end of 3 seconds, the body will be at B, 30 inches from A, but the paper itself will then have acquired the velocity of 6 inches per second, and will have moved through the half of 18 inches or 9 inches; that is, A C will be 9 inches. Hence the distance of the body from the middle line will be C B, or 21 inches. Relatively to the paper, the velocity of the body is uniform, but relatively to the table, it has a uniformly retarded velocity. At the end of the fourth second, it will have advanced 40 inches on the paper, and the paper itself will have receded 16 inches, giving 24 inches for C B. At the end of the fifth second, A B will be 50 inches, A C 25 inches, and C B 25 inches. At the end of the sixth second, A B will be 60 inches, A C 36 inches, and B C 24 inches, so that the body, with respect to the table, stops in the sixth second, and then begins to move back again. We can easily find when this takes place, for, since the velocity on the paper is 10 inches per second, and that of the paper gains 2 inches in every second, at the end of the fifth second the body will cease to move forward on the table. At the end of 10 seconds it will have returned to the middle line again, and afterwards will begin to move away from the middle line towards the left. At the end of the twelfth second, it will have advanced 120 inches on the paper, and the paper will have receded 144 inches, so that the body will be 24 inches on the left of the middle line.

The general algebraical formulæ which represent these results are as follow. Let a be the velocity with which the body begins to move, t the number of seconds elapsed from the beginning of the motion, g the velocity acquired or lost during each second. Then the space described in a uniformly accelerated motion from rest is $\frac{1}{2}gt^2$; when the initial velocity is a, the space described in an accelerated motion is $at + \frac{1}{2}gt^2$, and in a retarded motion the body will have moved through $at - \frac{1}{2}gt^2$ in the direction of its initial velocity if at be greater than $\frac{1}{2}gt^2$, or will have come back and passed its first position on the other side by $\frac{1}{2}gt^2 - at$, if at be less than $\frac{1}{2}gt^2$. In the last case it continues to move in the direction of its initial velocity for $\frac{a}{g}$ seconds and proceeds in that direction through the space $\frac{1}{2}\frac{a^2}{g}$

For further explanation as to velocities which are accelerated or retarded, but not uniformly, see VELOCITY.

ACCELERATION AND RETARDATION OF TIDES are certain deviations of the times of consecutive high-water at any place from those which would be observed if the tides occurred after the lapse of a mean interval. The interval between the culmination of the moon, or the occurrence of her principal phases, and the nearest time of high-water, is also called the retardation of the tide.

The tides are caused by the attractions exercised by both the sun and moon on the waters of the earth; but the effect produced by the moon exceeds that which is produced by the sun, and the difference is such, that the phenomena of the tides depend principally on the former. The mean interval between two consecutive returns of the moon, above and below the pole, to the meridian of any place, is 24h. 50m. 28·32s.; and since, neglecting all causes of irregularity, two lunar high-tides occur in that time, the mean interval between two consecutive lunar tides should be 12h. 25m. 14·16s.; while the mean interval between two consecutive solar tides should be 12h. Hence, if at the time of a conjunction or opposition of the sun and moon, the high tides which are produced by the actions of the luminaries separately were coincident, the next lunar tide would be retarded with respect to the next solar tide, by 25m. 14·16s., that is, by the excess of half a lunar day above half a solar day. These retardations continuing daily, the lunar high-water would coincide, at the time of quadrature, with the solar low-water, and thus produce the neap or diminished tides; after which, the like retardation continuing, the solar and lunar high-waters would again become coincident at the times of syzygy, and so on. The observed daily retardation of the lunar high-tides varies however according to the position of the moon with respect to the sun, to the moon's declination, and to the distance of that luminary from the earth. At Brest, when the sun and moon are in conjunction or in opposition, at the summer or winter solstice, the retardation is equal to 40m. 51·69s., and at the time of the equinoxes 37m. 38·15s. Again, when the sun and moon are in quadrature at either solstice, the retardation is 1h. 7m. 27·49s., and at the time of the equinoxes 1h. 23m. 16·34s.

If the earth were a solid of revolution, and were covered by the sea, the high tides produced by the sun and moon separately would, at any place, occur at the instants when those celestial bodies are on the meridian of the place; but such is not the fact in the actual condition of the earth; and local circumstances produce, at different ports, great differences in the intervals between the culmination of the sun or moon at the time of high-water, even on the days when the luminaries are in conjunction or opposition. The interval between the instant that the sun passes the meridian of a place and the occurrence of the solar high-tide, is found to be greater than the interval between the transit of the moon and the occurrence of the lunar high-tide; and this acceleration, as it is called, of the lunar tide, is with much probability ascribed by Dr. Young to a difference in the resistances experienced by the waters on account of the different velocities which are communicated to them by the separate actions of the sun and moon.

It should be observed however that at Ipswich the time of high-water is nearly coincident with the time at which the moon passes the meridian of that port; and both at Glasgow and Greenock, the high-tide generally precedes the transit (Mr. Mackie's 'Report,' at the seventh meeting of the British Association); but such phenomena are of rare occurrence, and at almost every place the high-tide occurs some time after the moon has culminated.

From a series of observations continued during sixteen years, at Brest, La Place, taking the excesses of the height of the evening tide above that of the morning for the day of syzygy, for the day preceding it, and for four days following it, has ascertained that at the syzygies which occur about the vernal and autumnal equinox the highest tides at that port take place 1·48013 days after the instant of the conjunction or opposition; and at the syzygies which occur about the summer and winter solstices they take place 1·54684 days after conjunction or opposition. Again, taking the excesses of the height of the morning tide above that of the evening for six days, as above, he ascertained that at the quadratures which occur about the equinoxes the highest tides take place 1·50964 days after the instant of quadrature, and at the solsticial quadratures 1·51269 days after such instant.

Mr. Airy ('Tides and Waves,' Encycl. Metrop.) observes that these retardations cannot be accounted for by delays in the transmission of the tide-waves, since no cause for such delay can be imagined to exist in the Southern Ocean, where the waves are formed; and it is known that the time of high-water at Brest is only fifteen hours later than at the Cape of Good Hope: he conceives, therefore, that the retardation must be ascribed to friction. By taking the means of the daily retardations of the morning and evening tides at Brest, La Place found that at the equinoctial syzygies such mean retardation was equal to 37m. 38s.; at the solsticial syzygies, 40m. 52s; at the equinoctial quadratures, 83m. 16s.; and at the solsticial quadratures, 67m. 27s.

From a series of observed heights of the tides, Sir John Lubbock has determined that the highest tides occur at London 2·013 days after the conjunction or opposition of the sun and moon; and at Liverpool, 1·68 days. ('Phil. Trans.' 1831, 1835.) Also, from the observed heights, Dr. Whewell has found that the highest tides occur at Bristol 1·667 days after the syzygies; and at Dundee 1·639 days. ('Phil. Trans.' 1838, 1839.) On the supposition that the mean retardation of the tide at London at the times of syzygy is 2·459 days, Mr. Airy has computed the moon's true hour-angle west of the meridian, at the time of high-water, for every half hour's difference in the time of her transit; and from the table it appears, that when the moon passes the meridian of London at noon (that is, at the time of conjunction), that angle, in time, is 1h. 57m. 17s.; when it passes at 3 P.M., the angle is 1h. 10m. 45s.; at 6 P.M., or at quadrature, 0h. 41m. 17s.; and at 9 P.M., 1h. 55m. 29s. The hour angle is the greatest at $10\frac{1}{2}$ P.M., when it is equal to 2h. 9m. 55s.; and at $11\frac{1}{2}$ P.M., or nearly at the time of opposition, it is 2h. 3m. 9s.: all these times are found to agree very nearly with the results of observation. From such results it is ascertained that, on the days following the times of syzygy and quadrature, the intervals between the time of the moon's transit and the instant of high-water are nearly equal; but from conjunction to the first quarter, and from opposition to the third quarter, the intervals are less than on the days of syzygy and quadrature, or the time of high-water is accelerated; while from the time of the first quarter to that of full moon, and from the third quarter to the new moon, the interval is greater, or the time of high-water is retarded. The time first mentioned (1h. 57m. 17s.) is that which is called the Establishment, at London; but Dr. Whewell recommends that the mean of the times (1h. 25m. 35s.), which he calls the mean, or correct, establishment, should be used in preference, because it differs less, on any day, from the vulgar establishment.

From Dr. Whewell's paper in the 'Philosophical Transactions' for 1836, we find that at Liverpool, when the moon passes the meridian at 30m. P.M., her hour-angle at the time of high-water is 11h. 18m. 16s.; when the hour of transit is 6¼ P.M., the hour-angle is 10h. 40m. 52s.; and when it is 11¼ P.M., the angle is 11h. 33m. 36s. The mean, or correct establishment, at that port, is 11h. 6m.

The acceleration and retardation of the times of high-water must evidently depend on the distance of the moon from the earth, and they are presumed to be proportional to the difference between the actual and the mean horizontal parallax of the luminary: this is called the parallax inequality of the tides; and La Place has determined, for the lunar tides, that the ratio of the daily variations, when the moon is in apogee and in perigee, is nearly as 2227 to 2899. He estimates the variation at 9m. 26·4s. for a change equal to one minute in the moon's apparent semidiameter at the times of conjunction and opposition, and at one-third of that quantity at the times of quadrature. Corresponding variations, but less in amount, take place with respect to the solar tides.

ACCENT (in Mathematics). To avoid the confusion arising from the use of many letters in an algebraical problem, and on other accounts, it is customary to signify different magnitudes of the same kind, or magnitudes similarly connected with the question, by the same letter, distinguishing these magnitudes from one another by accents. It is, therefore, to be understood that the same letter with two different accents may stand for magnitudes as different in value as those represented by different letters. The convenience of the accent may be illustrated as follows:—If a men can do b things in c days, and e men can do f things in g days, we have the following equation:—

$$a\, f\, c = e\, b\, g.$$

Now, instead of using e, f, and g, in the second part of the question, let us use the letters which stood for the corresponding quantities in the first part, with accents; that is, let a' men do b' things in c' days. The equation then becomes

$$a\, b'\, c = a'\, b\, c'.$$

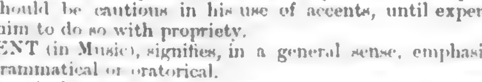
In this new form of the equation some things are evident to the eye, to ascertain which, had the first equation been used, we must have had recourse to the question itself. For instance, that if a'', b'', c'' express men, things, and days, as above, $a\,b''\,c = a''\,b\,c''$, only placing two accents now where there was one before. In many investigations, the judicious use of accents gives a symmetry to the processes and expressions which could scarcely be otherwise obtained.

For the unmathematical reader, we may illustrate the use of accents in the following way:—Let us suppose a bookcase to consist of four rows of shelves, each divided into six compartments. If we call the six compartments in the lowest range A, B, C, D, E, and F, respectively, we might let the compartment directly over A be called G, and so on; but it would be much simpler and more easy of recollection to call this compartment A′, the one over *it* in the third row A″, and so on. Thus each letter would indicate a certain vertical line of compartments, while the accent would point out in which horizontal line the one designated is to be found. This is precisely the mathematical use of the accent. All quantities of the same kind, or which the problem places in similar positions, are designated, with regard to this question, by the same letter.

The accented letter a' is read *a accented*, or *a dashed*; a'' is read *a twice accented*, or *a twice dashed*, or, more conveniently, though without much attention to idiom, *a two dash*, &c. When accents become too many to be used with convenience, the *Roman* figures are substituted for them. Thus a^{iv} would be used for a'''': at Cambridge, of late years, the i and v are an accent, and two accents joined at the base, which is very expressive. The Roman figures prevent a^{iv} from being taken for a^4, or a multiplied three times by itself. The young algebraist should be cautious in his use of accents, until experience has taught him to do so with propriety.

ACCENT (in Music), signifies, in a general sense, emphasis, and is either grammatical or oratorical.

Grammatical accent is the emphasis, always slight, given to notes which are in the accented parts of a bar. If the first, fifth, and ninth notes of the following series are accented, the whole will be divided into bars of common or equal time:



If an emphasis be given to the first, fourth, and seventh notes, the series will divide into bars of triple time—thus:

Again, an entirely different effect will be produced by throwing the accent on the second, sixth, and tenth notes of the same series:

So important is this accentuation, that the above examples give really different tunes, although the notes are the same.

Oratorical accent is expression—is the accent dictated by feeling—and not confined to any particular part of the bar. It is often required, though the composer may not have marked it by any sign, but left it to the knowledge and taste of the performer to discover and enforce. Commonly, however, the terms *rinforzato* (strengthened), and *sforzato* (violently forced), are used for the purpose, though these participles are too often thought synonymous. An acute angle (>) is also employed to indicate such emphasis.

The accented parts of a bar are such as naturally require some emphasis. In common time, the bar of which is divided into four parts, the first and third are accented, the second and fourth unaccented. In triple time of three crotchets, the accent is on the first; the second and third are usually unaccented; but a slight accent is sometimes given to the third or last note. In three-quaver time the accent is on the first quaver only. In six-quaver time, it is on the first and fourth quavers. Nine-quaver and twelve-quaver times, which are only multiples of the two former, and are seldom used, follow the same rule as those. The extremes, however, of slowness and quickness in times, though not altering their names, change the number of accented parts. [CLEF; TIME.]

ACCENT. When a child begins to read, he is apt to pronounce all the syllables of a word in the same key, with the same loudness and clearness, dwelling the same time upon each, and pausing the same time between each pair. He soon, however, learns that, in nearly every word there is one syllable at least which must be distinguished from the rest by a more impressive utterance, as in the examples *respéct, respéctful, respéctable.* If the word is a long one, it requires a second accent, as *respèctabílity, mànufáctory, immórtalìse.* On the other hand, when short words come together, one or two are often devoid of accent, as in the phrase *ón the tóp of a híll.* When it is stated that the accented syllable is pronounced more impressively than the rest, it is not meant that all accented syllables are to be equally impressive. In the examples given above, the first accent in *mánufáctory* seems to be weaker than that on the third syllable; so the last accent in *immórtalíse,* and that attached to the prepositon *on*, among the six monosyllables, *ón the tóp of a híll,* are comparatively very faint. The consideration of accent often determines whether or not we pronounce the initial *h* [See A or AN]; and, consequently, whether the article *an* or *a* is to be used before such a word. Upon accent depends the melody of verse, at least in modern languages. Of the ancient, particularly the Greek accent, it is better to abstain from speaking, because the opinions of people on the subject of Greek accent are both unsettled and contradictory. We may remark, however, that it is the practice of the modern Greeks, in a very great number of instances, to put the chief stress on that syllable which, in our printed Greek books, has the accentual mark (′) on it; but, in doing this, they frequently and unavoidably neglect the stress on those syllables which we are accustomed to pronounce most emphatically. It is said that the principle of Greek versification is *quantity*, or, as it is defined, the mere duration of a sound. Possibly, on a closer examination of the question, it would be found, that what the ancients meant by *quantity*, was not very different from what we mean by *accent*. A writer in the 'Transactions of the Philological Society for 1855' (pp. 119—145), has put forward arguments to show, that to accentuate the writings of Homer, Æschylus, Thucydides, as is the present practice, is simply an anachronism, inasmuch as the accentual marks were introduced at a much later period for the very purpose of denoting the changes of pronunciation, when the distinctive vowels *ω* and *η* were no longer trustworthy guides. It does not accord with the nature of the present work to enter into details; but we may be permitted to say, that the challenge to scholars contained in the paper has not yet been accepted. To return to the safer ground of our own language, the reader of our older writers, Shakspere and Milton, for instance, should know that the accents of words from time to time are changed, and even variable at the same time. Thus, the verb which we call *tríumph*, was with Milton generally *triúmph;* the noun and the verb being commonly distinguished by him in the same way as *próduce* the noun and *prodúce* the verb are at the present day. What we call *spirit*, was with him more commonly *spirite*, or almost *sprite;* and *áspect, prócess,* were *aspéct, procéss.* Even in our time, *advertisement* has become *advértisement.* In these changes, the usual tendency in our language is, and has been, to throw the accent farther back from the end of the word. Such a tendency is, perhaps, inherent in all languages, and seems to arise solely from an endeavour to save labour by rapidity of utterance.

The symbols employed to denote accents are three, the acute (ʹ), the grave (ˋ), and the circumflex (ˆ). We have hitherto spoken only of the first. The second in the ancient languages is said to denote the opposite to the acute, or, perhaps, the absence of it; while the circumflex, we are told, marks a compound of the two, first a rising and then a falling of the voice in the articulation of the same syllable.

These three little marks, as employed the orthography of the French language, have a signification altogether different. As the French, like all other languages, is deficient in the number of characters used to mark the vowel sounds, it has been found convenient to employ the three symbols given above. Thus, the sounds of *e*, *é*, *è*, *ê*, in the mouth of a Frenchman, differ not so much in point of *accent* as in the real articulation.

Emphasis differs from *accent*, and is properly used with reference to some one word, or part of a sentence, to which a speaker wishes to draw attention by giving it a more marked pronunciation. [EMPHASIS.]

ACCEPTANCE. [BILL OF EXCHANGE.]

ACCESSARY (from the low Latin *accessorius* or *accessorium*), is, in law, one who is guilty of an offence which is a felony, not as chief actor, but as a participator without being present at the time of the actual committing of the offence, as by command, advice, instigation, procurement, or concealment, &c.

A man may be accessary either before the fact, or after it.

An *Accessary before the Fact* is defined by Lord Hale to be one who, "being absent at the time of the crime committed, doth yet procure, counsel, or command another to commit a crime." The offender's *absence* is necessary to constitute him an accessary, as otherwise he would be a principal; and he must have procured the commission of the crime, either by direct communication with the actual perpetrator, or by conveying his advice or command through some indirect channel. But the mere concealment of a felony intended to be committed, without actual instigation, will not make a man an accessary; as that is only a misprision of felony. It is an established rule, that where a man commands another to commit an unlawful act, he is accessary not merely to the act commanded, but to all the consequences that may ensue upon it, except such as could not in any reasonable probability be anticipated or feared: as, for instance, if he commands another violently to beat a third person and he beats him so that he dies, the person giving the command is guilty as accessary to the murder consequent upon the act, notwithstanding that it may never have been his intention that a crime of so deep a dye should be committed. But a man will not be guilty as accessary before the fact if he command another to kill A, and he kills B, because the particular crime he contemplated has never been completed. It is otherwise where the directions have been substantially pursued, although the crime may not have been committed precisely in the manner in which it was commanded to be done, as where a murder is effected by means of stabbing instead of poisoning.

An *Accessary after the Fact* is one who, knowing a man to have committed a felony, receives, harbours, or assists him. In general, any assistance given to a felon to hinder his being apprehended, tried, or suffering punishment, as by affording him the means to escape the pursuit of justice, will constitute the assister an accessary after the fact; but it is not so if the assistance given have no such tendency, as when clothes or necessaries are supplied to a felon in gaol. Although any act done to enable the criminal to escape the vengeance of the law will make a man guilty as accessary after the fact, a mere omission to apprehend him, without giving positive assistance, will not have that effect. Also, if the crime be not completed, at the time of the relief or assistance afforded, the reliever or assister is not judged an accessary to it; as where a mortal wound has been given, but the murder is not then consummated by the death of the party: yet, the crime once complete, not even the nearest ties of blood can be pleaded in justification of concealment or relief, except alone in the case of a wife, whom the law supposes to be so much under the coercion of her husband, that she ought not to be considered as accessary to his crime by receiving him after it has been committed.

By 7 Geo. IV. c. 64, and 11 & 12 Vict. c. 46, the trial and punishment of accessaries *before* the fact is assimilated to that of the principal felon. Accessaries *after* the fact are, by the latter statute, made punishable as for a substantive felony, with imprisonment proportioned to the heinousness of the original crime, but the imprisonment is not to exceed two years. The receiver of stolen goods, whose offence is of the nature of that committed by an accessary after the fact, is, by 7 & 8 Geo. IV. c. 29, made liable to fourteen years' transportation: or now to a similar period of penal servitude; 16 & 17 Vict. c. 99; 20 & 21 Vict. c. 3.

Formerly no accessary could be tried until after the conviction of the principal, the crime of the former being regarded as, in a manner, dependant on that of the latter; but the law is now altered in this respect, by 11 & 12 Vict. c. 46; and 14 & 15 Vict. c. 100. It is now competent to try and convict him without waiting for the conviction of the principal.

The distinction between principals and accessaries holds only in cases of felony.

ACCIDENT. [PREDICABLES.]

ACCIDENTAL COLOURS. A term applied to the ocular spectrum which is usually seen when the eye has been steadily fixed for some time upon a coloured object. Thus, if we look at a red wafer upon a sheet of white paper for about half a minute, and then turn the eye from the wafer to the white paper, we see an image, or spectrum, of the wafer of a bluish green colour; this is the accidental colour of the red, and if we repeat the experiment with other colours, they will in like manner furnish ocular spectra: thus an orange colour will furnish a blue spectrum, yellow will give indigo, and so on, and it will be found in each case, that the colour of the object, added to that of the spectrum, will make up all the colours of white light; hence accidental colours are also called *complementary colours*. [LIGHT.]

ACCLIMATION is a term applied to that change in the human system produced by residence in a place whose climate is different from that to which it has been accustomed, and which enables it to resist those causes of disease which readily act upon it before such change has taken place. A person is thus rendered similar in constitution to the natives of the country which he has adopted. This subject is one of great importance, and has not yet received the attention it demands. As far as present evidence goes, it appears that the white races attain their highest physical and intellectual development, the greatest amount of health, and reach the greatest age, above 40° in the western and 45° in the eastern hemispheres. Whenever they pass below these latitudes they begin to deteriorate and exhibit unmistakeable symptoms of decadence in both health and strength. The same law holds good with the dark races of the tropical parts of the earth. The negro who lives in the interior of Africa is killed by cold. The limits of his health and strength are found at 40° north or south. If he proceeds to higher latitudes, he deteriorates and becomes exterminated. In the northern states of America the mortality of the black population is double that of the white.

"The laws of climate show that each race of mankind has its prescribed salubrious limits. All of them seem to possess a certain degree of constitutional pliability by which they are able to bear, to a certain extent, great changes of temperature and latitude; and those races that are indigenous to temperate climates support best the extremes of other latitudes. The inhabitants of the arctic regions, as also of the tropics, have a certain pliancy of constitution; and while the inhabitants of the middle latitudes may emigrate 30° south or 30° north with comparative impunity, the Esquimaux in the one extreme, or the Negro, Hindoo, or Malay, in the other, have no power to withstand the vicissitudes of climate encountered in traversing the 70° of latitude between Greenland and the equator. The fair races of northern Europe below the arctic zone find Jamaica, Louisiana, and India, to be extreme climates; and they and their descendants are no longer to be recognised after a prolonged residence there. When an Englishman is placed in the most beautiful part of Bengal or Jamaica, where malaria does not exist, and although he may be subjected to no attack of acute diseases, but may live with a tolerable degree of health his threescore years and ten, he nevertheless ceases to be the same healthy individual he once was; and, moreover, his descendants degenerate. He complains bitterly of the heat, and becomes tanned; his plump plethoric frame becomes attenuated; his blood loses fibrine and red globules; both mind and body become sluggish; gray hairs and other marks show that age has come on prematurely—the man of forty looks fifty years old; the average duration of life is shortened (as shown in life insurance tables); and the race in time would be exterminated if cut off from fresh supplies of emigrants from the home country. Our army medical historians tell us that our troops do not become acclimatised in India. Length of residence in a distant land affords no immunity from the diseases of its climate, which act with redoubled energy on the stranger from the temperate zones. On the contrary, the mortality among officers and troops is greatest among those who remain longest in those climates." (Johnson, Martin, Tulloch, Macpherson, Boudin.) Dr. Macpherson also makes the significant remark, that the small mortality among officers compared with soldiers, in India, is due to the greater facilities they enjoy of obtaining change of climate when they fall sick. Although the constitution of the man may be so modified that comparative health may be retained, yet there is a morbid degradation of the physical and intellectual constitution. If, however, he or his descendants are taken back to their native climate, they may yet revert to the healthful standard of their original types. The good effects of limiting the period of service of our troops abroad to three years, has shown this in sustaining for a greater period the strength of the regiments; a protracted residence of the European regiments in India having been followed by the most disastrous results. "European regiments in India have melted away like the spectres of a dream. A thousand strong men form this year a regiment: a year passes, and one hundred and twenty-five new recruits are required to fill up the broken column; and eight years having come and gone, not a man of the original thousand remains in the dissolving corps."

"With regard to the Bombay Fusilier European regiment, for instance, Dr. Arnot has shown that its losses average 104 per 1000 per annum; a loss equivalent to the entire absorption of the regiment in nine years and seven months. In Bengal also it is an ascertained fact, that a British regiment of 1000 men dissolves entirely away in 11 years, even in favourable times, and with all the improved conditions of the service. Dr. Arnot's statistics show that the Bengal army loses annually 9 per cent. of its numbers, giving a total loss in eight years of upwards of 14,005 men out of an army of 156,130 men." (Aitken's 'Handbook of Medicine.')

In the island of Ceylon the rate of mortality has been recorded amongst five different races of which the British troops are composed. The following table gives the result:—

	Annual death in 1000 men.
Native troops of Bengal and Madras	12
Troops recruited on the coast of Ceylon	23
Malays	24
Negro troops	50
English troops	69

Although from these facts it would appear there is an insuperable barrier to the prolonged occupation of tropical countries by white races, yet much may be done by attention to the laws of health and disease. One cause of the great amount of mortality amongst Europeans in the tropics is that they continue the habits they had acquired in cold countries when they arrive in the hotter parts of the world. An attention to diet, clothing, and residence, would do much to remove many of the causes of disease. It would appear also that many of the races that now inhabit cold climates made their way from warmer countries, and that changes gradually produced in the constitution, as by the slow advance of peoples north or south, may overcome that tendency to succumb which is so evident in the rapid removals to which the above data refer. The question of the permanent occupation of tropical countries has become one of vital importance to the two great European governments of England and France. How this can be done at the least expense of human life can only be ascertained by the study of the laws which regulate acclimation.

ACCOLADE. This French word, derived from the Latin *ad*, to, and *collum*, the neck, signifies, in familiar speech, an embrace; and this idea, or that of union by means of the neck, as when two oxen are yoked together, is that which prevails in various other derivatives from the same root, both in the French and Italian languages. Some, accordingly, have supposed that, when used as descriptive of a certain part of the ancient ceremony of conferring knighthood, the particular act which it denoted was the embrace, accompanied with a kiss, which was bestowed upon the new-made knight, in token of the brotherhood established between them by his admission into the order of chivalry. It has, however, been the more generally-received opinion, that the accolade was what we call in English (though perhaps improperly) the dubbing, the slight blow given to the cheek or shoulder of the knight, "as an emblem," to use the language of Gibbon, "of the last affront which it was lawful for him to endure." There is no doubt as to the great antiquity of this last-mentioned custom. Gregory of Tours, writing in the 6th century, describes the blow on the shoulder as part of the ceremony with which the kings of France, of the first race, were wont to confer the honour of knighthood. It has been derived, by some antiquaries, from the blow which the Roman slave received from his master when manumitted, or made a freeman. The blow of liberation, indeed, whatever may have been its original import, may be traced in various directions among the usages of the middle ages. The blow by which knighthood was conferred seems to have been originally given with the hand, for which the flat part of the sword was afterwards substituted.

ACCOMPANIMENT, in Music, is the subordinate part, or parts, accompanying a voice, or several voices, or a principal instrument, &c. The piano-forte or guitar part of a song is the accompaniment, the air itself being the principal, the other only the useful ally, the support. In a concerto the whole band accompany the instrument for which the chief and prominent part is composed.

Accompaniment is also the harmony of a figured base, or another word for what is, by a foolish, unmeaning term—but too generally adopted to be at once discarded—called thorough-base.

The Accompaniment of the Scale is the harmony assigned, partly by what may be called nature and partly by custom, to that series of notes denominated the diatonic scale ascending and descending, such scale being taken as a base. For an explanation of these matters, see THOROUGH-BASE. See also DIATONIC; SCALE.

Dr. Burney (in Rees' 'Cyclopædia') seems inclined to favour the opinion of Rousseau, that an accompaniment of the smallest possible number of notes is to be preferred. Rousseau had not acquired a taste for rich harmony, for with the music of the German school he was very little, if at all, acquainted; but that Burney should have sanctioned opinions formed upon the imperfect knowledge of the subject existing in the middle of the last century, is somewhat a matter of surprise. A judicious medium, in this as in other things, is the best. The old Italian accompaniment can now hardly be endured; while, certainly, many ultra-Germanists of the present day overpower melody by the multitude of notes which they are so prone to employ.

ACCOMPLICE. [APPROVER.]

ACCOMPTS. [BOOKKEEPING.]

ACCORDION. A musical instrument which came into England, from Germany, about the year 1828.

The Accordion is in the form of a small oblong box, varying from eight to twenty inches in length. The interior exhibits a row of very small elastic metallic laminæ, or springs, fixed at one end in a plate of metal, so that they may vibrate freely. The upper and lower parts of the box are united by a folding apparatus or bellows, which supplies the air required to put the springs into vibration, and to these the air is admitted by means of valves acted on by keys, in the manner of an organ. There is also a very simple contrivance by which a base note or drone may be added, at the discretion of the performer. These instruments vary in size and in capabilities: the compass of the most complete is from G the fourth space in the base staff, to E the seventh additional space above the treble, including all the semitones. Hence the accordion is not limited to melody, but can produce the most agreeable harmonic effects.

The principle on which the accordion, and all other instruments of the kind, is founded, is fully explained by Dr. Gottfried Weber, in his 'Leges Oscillationis,' &c., published in 1827, who refers, as his source of information, to an article by Strohmann, in the 'Allgemeine Musicalische Zeitung' of 1813. This principle, however, had been fully set forth many years before by Professor Robison, in the 'Encyclopædia Britannica,' under the term 'Musical Trumpet;' and it is now known that the Chinese were familiar with it before its introduction into Europe.

The firms of Reinisch and Steinkeller, at Vienna, sent large collections of beautiful accordions to the Great Exhibition of 1851; as did also Wagner of Reuss, and Zimmerman of Carlsfeld. The 40-keyed accordions of the last-named firm were priced as low as six Prussian thalers (17*s.* 6*d.*). Small and roughly-made German accordions are now sold in England at extremely low prices. In the commoner instruments, each key is made to elicit two different tones, according as the wind is made to pass into or out of it; but, in some of the better kinds, there are as many keys as notes.

The gentle tones of this beautiful instrument are found to be so attractive to the inhabitants of rude nations, that Roman Catholic missionaries have lately, in some instances, adopted the plan of taking accordions out with them. In musical capability, however, the accordion is far inferior to an instrument of later introduction. [CONCERTINA.]

The *Flutina* is a form of the accordion in which, by a mode of partitioning the interior cavity into cells, a peculiar flute-like quality is given to the tones.

The *Organ-accordion*, a recent invention, has a row of black and white keys like those of the organ or pianoforte, giving all the tones and semi-tones for three octaves. These keys are played with the fingers of the right-hand, the left-hand being needed to work the bellows. The instrument, too large to be held in the hand, is rested either on a table or on the lap of the performer. It is intended chiefly as an accompaniment to the voice.

Mr. Faulkner has invented an accordion-stand. It is an apparatus to assist in playing the instrument; it will incline to any position suitable to the convenience of the performer; and, by the action of a spring-top, it can be fixed in the position chosen.

ACCOUNT, or ACCOMPT, from the low Latin, *computus*, is a form of action, and of which frequent mention is made in the old law books. Strictly, it lay only against a bailiff or receiver, requiring him to render an account of the moneys received by him as such; but the form of action being found to be one of the most convenient at that time, it was extended to cases where the person called upon to account was neither a bailiff nor an authorised receiver, if he had in any way received and retained money which it was his duty to have handed over to the claimant. At present, this is effected in many cases by the action for "money received to the use" of the plaintiff. The action of account is now rarely used, a suit in chancery being generally resorted to.

(Blackstone's *Comm.*, Mr. Kerr's ed., vol. iii. pp. 171, 172.)

ACCOUNT STATED. This is the title of the common count in the declaration in an action, where the plaintiff seeks to recover the amount due upon a balanced account between the parties. The form states the defendant to be indebted to the plaintiff in a certain sum of money found to be due from the defendant to the plaintiff upon "accounts then stated" between them, from which statement of accounts the law implies a promise by the debtor to pay the sum he then admits himself to owe. This form is generally introduced in actions upon simple contracts for the recovery of pecuniary demands.

It is not essential that there should be cross or reciprocal demands between the parties, or that the account should relate to more than a single debt or transaction; nor need the original demand be one recoverable at law. Thus, a member of a partnership, though he cannot in general sue his partner at law for his share of the profits, may do so after a balance has been struck in his favour. But it is necessary that there should have existed some claim against the defendant, or some previous transactions in respect of which the account is stated, for an action cannot be brought in this form upon a mere agreement to pay a sum of money, the maxim being *ex nudo pacto non oritur actio.* It is, therefore, usual in support of this count to give evidence of an original demand or a prior transaction, and of a balance struck and agreed upon, but it is sufficient in the first instance, to prove an admission by the defendant to the plaintiff or his agent, that a certain sum was then due, without showing the origin or nature of the claim, or proving the specific items constituting the account. Thus an I. O. U., a bill, or a promissory note, is *primâ facie* evidence of an account stated betwixt the immediate parties. The account must have been stated before the action is brought; and the admission, in order to charge a defendant, must be positive, unqualified, and unconditional, and must not be merely the admission of a debt, but either expressly or by reference, the admission of a specific sum being due. If the plaintiff sues in a representative character, as in that of executor or assignee, he must show that the admission was made to him in that character. The statement of an account is not conclusive but only presumptive evidence against the party who admits the balance to be against him, and does not preclude him from showing, by evidence, the existence of error in the account; unless in the case of an account actually settled by payment, which cannot be opened except upon proof of fraud.

An account stated is also a good plea in bar to a bill in equity for an account. As a party may in equity open up a settled account on the ground of error, in order to support such a plea, the statement of account must be shown to have been final, and in writing. It is not essential that it should have been signed, and it will be sufficient if the account has been acquiesced in for a length of time, affording legal presumption of a settlement. A general release may thus be pleaded as a stated account, and a plea of this kind must aver that the account is just and fair, whether error or fraud is charged by the bill of the plaintiff or not.

In answer to a plea of a stated account the plaintiff in equity may show either the existence of fraud, which will be sufficient ground for opening the whole account, or that the account contains specific errors, which will enable him to surcharge, that is, to show omissions for which there ought to be credit, and falsify, that is, to show that there are wrong charges which ought to be deducted.

ACCOUNTANT, a person who professes skill in mercantile accounts. In a commercial community occasions are constantly arising for the employment of accountants. They are generally appointed to examine the books of traders who have been compelled by embarrassment in their affairs to summon a meeting of their creditors; or they may be called in by a trader to investigate his accounts, and to ascertain the state of his affairs. The collection of debts or rents, and the winding-up of the affairs of persons deceased, or who have given up business, are matters often put into their hands. An accountant has no legal status, like a notary or an auctioneer or appraiser, who perform certain duties which only they are allowed to discharge; but by the statute establishing District Courts of Bankruptcy, 5 & 6 Vict., c. 122, official assignees must be selected from persons in trade, or who are or have been "merchants, brokers, or *accountants*."

ACCOUNTANT IN BANKRUPTCY, an officer appointed by the Lord Chancellor (5 & 6 Will. IV. c. 29), who has the control, care, and management of the funds belonging to bankrupt estates. He must make an annual return to Parliament (13 & 14 Vict. c. 106, ss. 31, 36, 47, 191).

ACCOUNTANT-GENERAL, an officer of the Court of Chancery, first appointed under an Act (12 Geo. I. c. 32) "for securing the moneys and effects of the suitors." The Act recites that ill consequence and great prejudice already had, and might again, ensue to the suitors by having their moneys left in the sole power of the Masters of the Court. The bonds, tallies, orders, and effects of suitors were, it appears, until the passing of this Act, locked up in several chests in the Bank of England, under the direction of the Masters and two of the Six Clerks. The Act confirms a previous order of the Court of Chancery for adopting a different system, and sect. 3 enacts that, "to the end the account between the suitors of the High Court of Chancery and the Bank of England may be the more regularly and plainly kept, and the state of such account may be at all times seen and known," there shall be "one person appointed by the High Court of Chancery to act, perform, and do all such matters and things relating to the delivering of the suitors' money and effects into the Bank, and taking them out of the Bank, &c., which was formerly done by the Masters and Usher of the Court." The Accountant-General is "not to meddle with the suitors' money, but only to keep an account with the Bank." He attends several times a-week at the Bank and other places for the purpose of making sales, transfers, and acceptances of stock, according to the orders of the Court. The Bank receives moneys under a power of attorney from the Accountant-General. (As to the practice in the transfer of stock by and to the Accountant-General, see Daniell's 'Practice in Chancery,' 3rd edit. vol. ii. p. 1306, et seq.) His duties are in some respects regulated by the orders issued by the Court of Chancery. The salary is 3000*l.* a-year (under 15 & 16 Vict. c. 87, s. 22).

Before the passing of the Act 5 Vict. c. 5, which suppressed the equity jurisdiction of the Court of Exchequer, there was an Accountant-General of that court. The duties of the Accountant-General and Masters of the Exchequer are now performed by the Queen's Remembrancer.

There is an Accountant-General of the Irish Court of Chancery.

ACCUMULATION. [CAPITAL.]

ACCUMULATION. Before the passing of the statute 40 Geo. III. c. 98, a person might suspend the enjoyment of real or personal estate, and direct that the whole profits, rents, and produce thereof should be accumulated for a period not exceeding in extent that of any life or number of lives in being, and 21 years afterwards. The mischievous extent to which an individual at the close of the last century availed himself of this power of directing an accumulation, gave rise to the above statute, the object of which is to prevent the recurrence of a disposition of property so impolitic and unnatural.

The person in question was named Peter Thellusson. He was the son of Isaac de Thellusson, ambassador from Geneva to the court of Louis XV. He fixed his residence in London about the middle of the 18th century, and accumulated an immense fortune as a merchant. He died on the 21st of July, 1797. His name is now only remembered in connection with his extraordinary will, which led to the restraints upon testamentary dispositions above mentioned.

The property which was the subject of his will consisted of a landed estate of about 4000*l.* a-year, and of personal property to the amount of about 600,000*l.* This property he devised and bequeathed to trustees upon trust for accumulation and investment in the purchase of lands during the lives of his sons, grandsons, and the issue of sons and grandsons living, or *in ventre sa mere*, at the time of his death, and the lives of the survivors and survivor of them; and after that period, to be conveyed to the lineal descendants of his sons in tail male.

It had been long understood to be the rule of law that the absolute ownership of property might be suspended, and consequently the property rendered inalienable during lives in being at the time of the creation of the trust; that is, where the trust is created by will, at the time of the death of the testator. This period was afterwards extended so as to allow for the cases of infancy, and of a child *in ventre sa mere;* but it was for some time questioned whether a term of 21 years might in all cases be added to the period of suspension, though it has since been determined that it may. [SETTLEMENT.] Restraint on the accumulation of income was unknown to the common law, except in so far as the rule against perpetuities necessarily prevented accumulation from being carried beyond its limits; and Mr. Thellusson's will, by confining the restriction to existing lives, escaped the question which then existed as to the allowance of an absolute term of 21 years in addition to a life or lives in being at the time of the creation of the trust.

This will, which, in the events that happened, had the effect of postponing the usufructuary enjoyment of the bulk of the estate till the expiration of nine lives in being at the time of the testator's death, was, after many hard struggles, occasioned rather by the immense value of the property implicated (which it was computed would have amounted, with the expected accumulations, to upwards of 18,000,000*l.*), than by any new difficulty in the principle, finally established by the decision of the House of Lords on the 25th of June 1805. (Thellusson *v.* Woodford, 11 Ves. 112.)

The case of Thellusson *v.* Woodford gave rise to the Act of the 40 Geo. III. c. 98, "for restraining all trusts and directions in deeds or wills whereby the profits or produce of real or personal estates shall be accumulated and the beneficial enjoyment thereof postponed beyond the term therein limited." By the provisions of this Act, no person can settle or dispose of property by deed, will, or otherwise, so as to accumulate the income thereof, either wholly or partially, "for any longer term than the life or lives of any such grantor or grantors, settlor or settlors, or the term of twenty-one years from the death of any such grantor, settlor, devisor, or testator, or during the minority or respective minorities of any person or persons who shall be living or in *ventre sa mere*, at the time of the death of such grantor, devisor, or testator, or during the minority or respective minorities only of any person or persons who, under the uses or trusts of the deed, surrender, will, or other assurances directing such accumulations, would for the time being, if of full age, be entitled to the rents, issues, and profits, or the interest, dividends, and annual produce so directed to be accumulated. And in every case where accumulation shall be directed otherwise than as aforesaid, such direction shall be null and void, and the rents, issues, profits, and produce of such property so directed to be accumulated shall, so long as the same shall be directed to be accumulated contrary to the provisions of this Act, go to and be received by such person or persons as would have been entitled thereto, if such accumulation had not been directed."

It is now settled upon this statute, that a trust for accumulation reaching beyond the allowed period is good for the period allowed by law, and void only for the excess. (12 Ves. 295; 4 Russ. 403.)

ACCUMULATION OF POWER is a term applied to that quantity of motion which exists in some machines at the end of intervals of time, during which the velocity of the moving body has been constantly accelerated.

The simplest case in which there is such an accumulation of power is that of a heavy body, like the rammer of a pile-driving machine, which descends by the action of gravity during a certain time and impinges upon some object At the moment of impact, supposing that the object struck does not move, the velocities of all the particles which had gone on continually increasing during the descent, are destroyed, and thus a shock is produced immensely greater than that which would result from the mere pressure of the body. The battering-ram of the ancients when, being suspended from some fixed point it was allowed to swing by the action of gravity till one of its extremities struck the face of a wall, produced its effect in like manner by the power accumulated in it during its motion. In all such cases, the effect, if measured by the magnitude of an impression or indentation produced in the object struck, is, by Mechanics, directly proportional to the mass in motion, and to the square of the velocity at the instant of impact.

The accumulation produced by the continuous action of gravity, when a body has not far to fall, is commonly increased by that of a quantity of motion obtained by an exertion of muscular power. Thus a smith, when he would strike on an anvil with the greatest force, adds to the power of gravity on the hammer the accumulation of velocity arising from a whirling motion, in a vertical plane, which he gives above his head to the hammer before he allows it to descend.

In the old coining-machines which, like those at present used, produced the impression on the metal by the power of a screw, a great accumulation of force was obtained by causing a number of men to turn the horizontal bars attached to the vertical shaft which carried the screw: by the pressure of the men against the bars, while several revolutions were made about the axis of the screw, an acceleration of motion during that time took place; and the accumulation was instantaneously spent upon the metal, in aid of the pressure arising from the power of the screw alone. The like accumulation of force is obtained, but far more efficiently, in the coining-press of the present day by means of its fly-wheel; the reciprocating motion of a piston connected with a steam-engine communicates, by means of a crank, a continuous movement to the fly, and at the same time, a reciprocating rectilinear motion vertically to the cylindrical shaft (the stamper), on which the screw is formed. With half a revolution of the fly-wheel the stamper is lifted up, and with the other half it is forced down upon the metal.

When a fly-wheel is acted on by any prime mover, as wind, water, or steam, its motion continually accelerates, and a corresponding acceleration is induced in the wheel-work, in rollers, or in the stampers with which it is connected: the resistance to be overcome at what is called the working point destroys however this acceleration, and would allow the movement to be uniform, if it were not for the temporary accelerations or retardations which are caused by variations in the intensity of the moving power, or in the amount of the resistance; and these are almost wholly counteracted by the accumulated power which constantly exists in the fly.

ACCUSATIVE CASE, a term used in the grammatical system of the Latin language, and thence unnecessarily introduced into that of the English language. In Greek this case is not called *accusative*, but the same idea is expressed by a corresponding term in that language. In the article *ablative case*, the meaning of the word *case* was explained. In that article it was seen that the little syllable *em* is attached to the end of Latin nouns, and has the meaning of *motion to.* But where the simple Latin noun terminated in a vowel, the *e* of *em* was absorbed by that preceding vowel. Thus, to take an example, *Roma* was, and is, the name of the Roman capital, though, by Englishmen, generally corrupted into *Rome;* consequently, *to Rome* was expressed by *Romam* (a contraction from *Roma-em*); so, *in Romam*, expressed *into Rome. In Roma*, without the *m*, would signify merely *in Rome.* The accusative then signifying originally the object to which any motion is directed, was afterwards by a very natural metaphor, employed to distinguish the object of any action or feeling; thus, *incendere Romam, to burn Rome.* The Spanish and Portuguese have, in their languages, very closely imitated the Latin in this respect: *despidio de su casa à mi Dulcinea*—if translated word for word would be—he despatched from his house *to my Dulcinea;* but nothing more is meant than what we express by—he despatched my Dulcinea from his house. The *despatching* is with reference to Dulcinea. The employment of the letter *m*, with or without a weak vowel before it, occurs likewise in the Sanscrit language; and indeed in our own, in the pronouns *him* and *whom*, from *he* and *who*. The Greeks preferred the allied letter *n*, which is also found in some classes of the German nouns, as *den Grafen, the Count,* from the nominative *der Graf.* When the term *accusative case* is used in the grammar of our own language, it is only in this second or metaphorical sense, and, consequently, it is equivalent to what many grammars call by the better name of the *objective case*, or more simply the *object.*

ACETAL. (Formula, $C_{12}H_{14}O_4$.) A compound first formed by Döbereiner, and called by him oxygenated ether. It is produced by the slow oxidation of alcohol under the influence of platinum black. A number of watch-glasses containing platinum black, slightly moistened, are to be suspended in a tall wide-mouthed jar or bottle, and near the surface of some alcohol which must cover the bottom to the depth of about an inch. After the bottle has been left for two or three weeks in a warm place, it will be found to contain an acid liquid consisting of acetal, alcohol, aldehyde, and acetic ether. This is to be neutralised with carbonate of potash, as much chloride of calcium as will dissolve is to be added, and the whole subjected to distillation. The first fourth only of the product is to be collected, and chloride of calcium again added. A thin oily fluid rises to the surface, which is acetal, mixed with the before-mentioned impurities. Repeated treatment with chloride of calcium, at a gentle heat, in a retort, expels the aldehyde; caustic potash decomposes the ether, and washing with water removes the alcohol. After once more rectifying from chloride of calcium, the acetal is pure.

Acetal is a limpid colourless liquid, of an agreeable ethereal odour, and a taste resembling that of filberts. Its sp. g. is ·825, that of its vapour 4·24. It boils at 221°, is soluble in about 18 parts of cold water, and miscible with alcohol and ether in all proportions. Oxidising agents convert it into aldehyde and then into acetic acid. In contact with the air, alcoholic solutions of the alkalies convert it into aldehydic resin. It may be considered as a compound of 2 eq. of oxide of ethyle (ether) with 1 eq. of aldehyde.

$$\underset{\text{Ether.}}{2C_4H_5O} + \underset{\text{Aldehyde.}}{C_4H_4O_2} = C_{12}H_{14}O_4.$$

and, consequently, its formation from alcohol may be thus expressed—

$$\underbrace{3\left.\begin{matrix}C_4H_5\\H\end{matrix}\right\}O_2}_{\text{Alcohol.}} + O_2 = \underbrace{\left.\begin{matrix}C_4H_5\\C_4H_5\end{matrix}\right\}O_2 + \begin{matrix}C_4H_3O_2\\H\end{matrix}}_{\text{Acetal.}}\Big\} + 2\left.\begin{matrix}H\\H\end{matrix}\right\}O_2.$$

ACETAMIDE. [AMIDES.]

ACETANALIDE. [AMIDES.]

ACETATE. A salt arising from the displacement of the water in acetic acid, $HO, C_4H_3O_3$, by a base. Alkaline acetates and acetates of the alkaline earths may be formed by decomposing their carbonates with acetic acid and evaporating.

Acetate of Potash, $KO, C_4H_3O_3$, is a deliquescent salt crystallising with difficulty; it is used medicinally as a diuretic. It combines with another equivalent of acetic acid, forming a binacetate, $KO, C_4H_3O_3 + HO, C_4H_3O_3$, which crystallises readily, and when distilled is decomposed into the neutral acetate and monohydrated acetic acid.

Acetate of Soda, $NaO, C_4H_3O_3 + 6Aq.$, crystallises in oblique rhombic prisms. It is formed on a large scale in the preparation of acetic acid from crude wood vinegar. The latter is neutralised with chalk, forming acetate of lime, which being mixed with sulphate of soda is decomposed into acetate of soda, sulphate of lime being simultaneously formed.

Acetate of Ammonia (*Spirit of Mindererus*), $NH_4O, C_4H_3O_3$, cannot be well crystallised from its solution formed by neutralising the carbonate of ammonia with acetic acid, since on evaporation ammonia is expelled, and the solution becomes acid. It may be formed however by distilling equal parts of acetate of lime and sal-ammoniac, when binacetate of ammonia is given off as an oily fluid, which crystallises in needles. Dry ammonia converts it into the neutral salt. Acetate of ammonia has a cooling sweet taste and is a diaphoretic. Acetate of lime, $CaOC_4H_3O_3$, crystallises in needles which are efflorescent.

Acetate of Alumina is used largely as a mordant in dyeing. For this purpose it is made by decomposing a solution of alum with acetate of lime, in which case however the sulphate of potash, or ammonia of the alum, remains dissolved; the pure salt may be formed by substituting sulphate of alumina for alum, and acetate of lead for acetate of lime. According to Crum the formula of acetate of alumina is $Al_2O_3, 2C_4H_3O_3 + HOC_4H_3O_3$. Some of the metallic acetates are of great importance in the arts.

The *Proto-acetate* ($FeOC_4H_3O_3$), and the *Sesqui-acetate* ($Fe_2O_3, 3C_4H_3O_3$), *of Iron*, are both used as mordants by the calico printer. They are both made on a large scale by dissolving iron hoops, nails, or turnings, in crude pyroligneous acid. For the formation of proto-salt, access of air is prevented; for the sesqui-salt, encouraged. In Boucherie's process for preserving timber, the wood is impregnated with acetate of iron.

Neutral Acetate of Lead (*Sugar of Lead, Salt of Saturn*), $PbO, C_4H_3O_3, 3Aq.$, is prepared by dissolving litharge in excess of acetic acid; on evaporation, a mass of small white crystals is formed, resembling loaf sugar, but by careful management large transparent prismatic crystals of the salt may be obtained. It is very soluble in water and alcohol, and has a remarkably sweet taste.

Tribasic Acetate of Lead (*Goulard's Water*), $3\ PbO, C_4H_3O_3, 3Aq.$, is prepared by digesting seven parts of litharge with six parts of the neutral acetate of lead in thirty parts of water. It crystallises in minute needles. There are two other basic acetates of lead,—the subsesqui-acetate, $3PbO, 2C_4H_3O_3, Aq.$, and the hex-acetate, $6PbO, C_4H_3O_3, Aq.$, neither of which are of importance. All the subacetates of lead are decomposed by carbonic acid, and have a strongly alkaline reaction. They are employed in the refining of sugar. The neutral acetate of copper,—*verditer*, $CuO, C_4H_3O_3 + Aq.$, is formed by dissolving verdigris in hot acetic acid: on cooling, beautiful dark green crystals are formed. United with arsenite of copper, it forms Schweinfurth green, a beautiful green pigment.

The *Diacetate of Copper* (*Verdigris*), $2CuO, C_4H_3O_3 + 6Aq.$, is prepared commercially, by exposing sheets of copper to the action of acetic acid, produced from the fermenting marc of grapes. The copper becomes encrusted with the crystalline salt, which is removed and pressed into cakes. Pieces of cloth moistened with acetic acid are sometimes substituted for the grape marc.

Verdigris is decomposed by water into a soluble subsesqui-acetate, $3CuO, 2C_4H_3O_3 + 6Aq.$, and an insoluble tribasic acetate, $3CuO, C_4H_3O_3 + Aq.$

There are many other metallic acetates, few of which however are of much importance. They are most of them characterised by their ready solubility in water, and by yielding, on destructive distillation with lime, a volatile inflammable liquid called *Acetone*, q. v. Heated with hydrate of potash or soda, they yield hydride of methyl (light carburetted hydrogen).

Acetic acid forms soluble salts with many of the organic bases, some of which are of great importance in medicine.

ACETIC ACID constitutes the sour element of vinegar, and from it the latter derives its peculiar and valuable properties; vinegar in fact, in whatever way made, is dilute acetic acid, mixed generally with colouring matter, and some slight impurities.

Acetic acid exists in the juice of some plants, as will be shown when the chemistry of vegetable substances is treated of; at present it is to be considered as procured,—first, by the fermentation of saccharine matter; secondly, by the action of heat upon wood; the product of the former constituting vinegar, and that of the latter what was formerly called pyroligneous acid, but what is now largely employed, when purified, for most of the purposes to which vinegar is applied.

It is well known that when certain vegetable juices which contain much sugar are fermented, the first operation, if the heat be not too great, is that of causing the transformation of the sugar into carbonic acid gas and alcohol, the greater part of which last remains with the fermented juice: this is called the *vinous* fermentation, the product being wine if the juice of the grape have been employed. Now sugar is a compound of three elements, which also form alcohol,—viz. oxygen, carbon, and hydrogen; and while a portion of the two former unite to yield the carbonic acid, a part of the three combine to form alcohol or spirit of wine.

If the action is allowed to proceed further and with access of air, the acetous fermentation ensues: the alcohol absorbs oxygen, becoming aldehyde, and eventually acetic acid. The process may be thus symbolically expressed:—

$$\underbrace{C_4H_6O_2}_{\text{Alcohol.}} + 2O = \underbrace{C_4H_4O_2}_{\text{Aldehyde.}} + 2HO.$$

$$\underbrace{C_4H_4O_2}_{\text{Aldehyde.}} + 2O = \underbrace{HO,\ C_4H_3O_3}_{\text{Acetic Acid.}}$$

There can be scarcely a doubt that vinegar, as its name implies, was first procured, and most probably by accident, from the passage of the vinous into the acetous fermentation; and, in fact, it is now usually prepared in wine countries by exposing the wine in casks to the action of the air, at a temperature of about 76° of Fahrenheit's thermometer. Alcohol may also be converted into acetic acid by the action of finely divided platinum. If alcohol, slightly diluted, be allowed to drop on to platinum black, the oxygen condensed in the pores of the latter re-acts on the alcohol, converting it into aldehyde, which becomes, as shown above, acetic acid. This process has been employed on a large scale for the manufacture of the acid, but is now abandoned.

In this country vinegar is procured from an infusion of malt, termed *wort*, which is fermented in the usual way. It is then put into barrels, which are arranged in stoves, with their bungs out, and kept at a temperature of about 84° of Fahrenheit's thermometer. At this heat, which is considerably higher than that required for the vinous fermentation, carbonic acid is produced, which escapes as in the vinous fermentation; while oxygen is absorbed and thus acetic acid produced.

Vinegar thus procured is a well-known reddish-brown coloured liquid; its smell is rather pleasant and refreshing, and its taste is distinctly, but not intensely sour. The strongest malt vinegar is termed by the maker No. 24, and is calculated to contain 5 per cent. of real acetic acid; the manufacturer is allowed to mix with it one-thousandth part of its weight of sulphuric acid (oil of vitriol): vinegar, therefore, is not pure acetic acid, but is a mixture of a small portion of the acid, much water, a little sulphuric acid, spirit of wine, colouring matter, and mucilage.

Vinegar possesses the usual power of acids to redden vegetable blue colours; it combines with the alkalis, alkaline earths, and metallic oxides to form salts, which are termed acetates, some of which are of considerable importance, being largely used both in the arts and medicine.

Vinegar is purified from the sulphuric acid and colouring matter by distillation, but its smell and taste are then less agreeable: and although it is colourless, it cannot be conveniently or economically employed for the chemical purposes to which purer and stronger acetic acid is applied; not only on account of its weakness, but because the mucilage, which rises with it in distillation, renders the salts formed with it extremely difficult to purify. When vinegar is exposed to a low temperature, it is principally the watery part which freezes; and although the fluid portion is thus rendered stronger, it is unfit, on account of the presence of the colouring matter and sulphuric acid, for use as acetic acid.

The *second* method of obtaining acetic acid is by heating wood, as the dried branches of trees, in hollow iron cylinders, with a proper arrangement of coolers, or condensers and receivers.

The acid thus procured is called pyroligneous acid, and was at first supposed not to contain the acetic but a peculiar acid, different from all others. It is of a dark brown colour, has a strong burnt-acid smell, is very sour to the taste and acts strongly on vegetable blue colours. It contains a quantity of tar and oily matter; from these it is purified, in a considerable degree, by re-distillation, but it is still very impure. It is then mixed with chalk, becoming thus converted into acetate of lime, and the solution is concentrated by evaporation.

In order to render the acetic acid sufficiently pure, or rather to obtain an acetate fit for that purpose, the pyrolignite of lime is dissolved in water, and there is added to it a sufficient quantity of solution of sulphate of soda (Glauber's salt). The sulphuric acid contained in the sulphate of soda, and the lime in the acetate combine; and the sulphate of lime formed being very sparingly dissolved by the water, is precipitated in the state of a bulky powder: the soda of the sulphate at the same time unites with the acetic acid of the acetate of lime, forming acetate of soda. By proper evaporation crystals are obtained, which, by re-dissolving in water and again crystallising, may be rendered much purer. But if the salt should be still impure, it must be heated pretty strongly in an iron vessel. If the operation be carefully conducted, the tarry matter and other impurities only are decomposed by the action of the heat; the salt is then to be again dissolved in water and crystallised, and the crystals, after being once more pretty strongly heated to deprive them of their water, are sufficiently pure for the manufacture of pure acetic acid.

For this object 17 parts of dried acetate of soda are distilled with 10 parts of oil of vitriol at a moderate heat. The sulphuric acid combines with the soda as sulphate, and the acetic acid in its monohydrated or glacial form is expelled and condensed in a proper receiver.

$$NaO,\ C_4H_3O_3 + HO,\ SO_3 = NaO,SO_3 + HO,\ C_4H_3O_3.$$

The sulphate of soda thus formed is available for the future decomposition of the acetate of lime.

The acetic acid thus procured has the following properties: it is fluid and colourless, its smell is exceedingly pungent, and its taste very acrid and sour; if applied to the skin it occasions smarting, and even raises blisters upon it. When heated, the vapour which rises from it takes fire if a lighted taper is exposed to it. At about 45° of Fahr. a portion of this acid becomes solid and shoots into beautiful crystals; these contain no sulphurous acid, even though the product should not have been re-distilled; but a portion of sulphurous acid, formed during distillation by the decomposition of a part of the sulphuric acid, remains with the uncrystallised acid, from which it may be separated by mixing it with a small quantity of binoxide of lead (red lead) and re-distilling.

Acetic acid may also be obtained by the mere action of heat upon the binacetate of copper, or, as it is sometimes called, though improperly, *distilled verdigris*. The acetate of copper is first to be dried, so as to expel the greater part of the water of crystallisation, and then subjected to a pretty strong heat, in an earthen or glass retort, to which a receiver is to be properly adapted. The heat decomposes the salt, and the copper remains in the retort in the state of black or protoxide. The acid when first procured has a greenish tint, owing to the admixture of some protoxide of copper; it must be rendered free from this by re-distillation. This acid, though not quite so strong as that procured by the former process, is, however, still more concentrated than that required for general use.

The glacial or monohydrated acetic acid is, however, best procured by distilling dry binacetate of potash at a temperature not exceeding 550°. The following is the re-action:—

$$\underbrace{(KO,\ C_4H_3O_3 + HO,\ C_4H_3O_3)}_{\text{Binacetate of Potash.}} = \underbrace{KO,\ C_4H_3O_3}_{\text{Acetate of Potash.}} + \underbrace{HO,\ C_4H_3O_3}_{\text{Acetic Acid.}}.$$

The residual acetate of potash may be reconverted into binacetate, and repeatedly used for the same purpose. The specific gravity of monohydrated acetic acid, $HO,\ C_4H_3O_3$, at 62° F. is 1·063. It is liquid at temperatures above 55°. It crystallises at that temperature in radiating tufts of plates. Its sp. g. increases on dilution with water till three equivalents of the latter have been added, when it diminishes; and when diluted with an equal weight of water its sp. g. again becomes 1·063. Owing to this anomaly, the quantity of real acid in a solution cannot be estimated from the determination of its density. Glacial acetic acid mixes in all proportions with ether and alcohol. From the former it may be separated by the addition of water.

The uses to which acetic acid, in the state of vinegar, is applied are too well known to require notice; in the form of pyroligneous acid it is employed to preserve meat, and to impart to it the smoky flavour usually obtained by drying. Pure acetic acid is used in chemical researches, and especially for preparing various acetates. In a less pure state it is employed in the arts for preparing acetate or sugar of lead, acetate of copper or verdigris, and acetate of alumina, largely used by calico printers as a mordant.

Anhydrous acetic acid ($C_4H_3O_3$) was first obtained by Gerhardt. It may be produced by distilling three parts of oxychloride of phosphorous with eight of anhydrous acetate of potash. The liquid which passes over is to be returned on the residue and re-distilled till it no longer contains chlorine: it is then to be rectified. The liquid is colourless, boiling at 279·5°, and has a very pungent, irritating smell. The specific gravity of the liquid is 1·073, that of the vapour 3·47.

It gradually becomes converted into hydrated acid from the absorption of moisture.

Acetic Acid (*Medical properties of*). Vinegar produces very different effects according to its degree of concentration; its effects are also different on the dead and living organic tissues. It acts as an effectual preservative from the putrefactive fermentation of dead organic tissues, and is hence employed as the means of forming pickles, or meat in a dried state, by simply immersing the substance in it for a few minutes. Wood vinegar, or pyroligneous acid, is most efficacious for this purpose, owing to the creasote present in it. Crude pyroligneous acid is one of the most effectual applications to timber, both to prevent the dry-rot and the ravages of insects. Concentrated acetic acid acts on the living tissues as a caustic poison; applied to the skin it causes heat, redness, and rapid inflammation. The same is the case when taken into the mouth, or applied to any mucous membrane, which it blackens like sulphuric acid. When properly diluted and used in moderation, it heightens the vitality of the stomach and greatly promotes the digestive powers. Indeed free acetic acid is one of those always present in the stomach in a healthy state, and the substitution of lactic acid for it in that organ is one of the most common accompaniments of indigestion, especially in bilious persons. The peculiar property which vinegar possesses of dissolving gelatine points out the propriety of employing it as a condiment when veal or other young meats, or fish, are taken. Its powers are heightened by having aromatic or pungent principles dissolved in it, such as chillies or taragon. In cases of slow digestion the moderate use of vinegar impregnated with these is much to be commended; but the abuse of it is to be reprobated, as productive of serious evils. This is seen in the case of ladies who employ vinegar to retain a slender figure, and who thereby induce organic diseases, even cancer of the stomach. Vinegar assists the digestion of crude vegetables, and is appropriately used for salads. Its power over the nervous system is seen in cases of poisoning with narcotic poisons and in cases of drunkenness. In the former case care must be taken that the narcotic substance is completely evacuated from the stomach before administering it, otherwise much injury may result from a powerful acetate being formed. But after the removal of the poison nothing combats more effectually the secondary symptoms than vinegar, especially if coffee be dissolved in it. Few things will restore a drunken man to his senses more speedily than giving him vinegar to drink, hence the popular custom of putting pickles into the mouth of a drunken person.

Vinegar acts as a refrigerant and as a grateful drink in fever. It may be applied externally likewise to the palms of the hands of consumptive persons, to cool the hectic flush and prevent the subsequent clammy perspirations. In cases of commencing anasarca, or loss of tone of the skin in advancing life, vinegar is a very useful wash. In a concentrated form it is beneficial in some forms of ring-worm of the scalp; though crude pyroligneous acid is preferable, owing to the creasote which it contains. The vapour of strong acetic acid, simple or aromatised, is a powerful restorative when applied to the nostrils in impending fainting, or as a means of relieving headache. It was formerly regarded as a disinfectant, or a protection against plague and similar diseases, but it merely overpowers and does not destroy unwholesome odours; free ventilation is therefore preferable. Acetic acid acts as a powerful solvent both of gum resins, the action of which it thereby increases, such as assafœtida and other vegetable principles, such as those of colchicum, squill, &c., and also of metallic oxides, such as copper.

The vapour of acetic ether carefully introduced by a suitable apparatus through the Eustachian tube into the ear, is very efficacious in restoring hearing in cases of nervous deafness. (Pilcher, *On the Ear.*) Strong acetic acid, either alone or having the active principle of cantharides dissolved in it, furnishes a ready means of forming a blister.

In cases of poisoning by strong acetic acid, chalk should be instantly administered.

ACETIC ETHER. [Ethers.]

ACETINES, artificial oils formed by the direct union of acetic acid with glycerine. They were first made by Berthelot, who has also succeeded in combining some of the fatty acids with glycerine, forming natural fats. There are three compounds with acetic acid. In the act of formation, the elements of water are always separated:

$$\text{Monacetine} = C_{10}H_{10}O_8 = HO, C_4H_3O_3 + C_6H_8O_6 - 2HO.$$
$$\text{Diacetine} = C_{14}H_{12}O_{10} = 2(HO, C_4H_3O_3) + C_6H_8O_6 - 4HO.$$
$$\text{Triacetine} = C_{18}H_{14}O_{12} = 3(HO, C_4H_3O_3) + C_6H_8O_6 - 6HO.$$

Monacetine is formed by heating a mixture of glacial acetic acid and glycerine to 212° for fourteen hours. It is a neutral liquid, possessing a peculiar odour and pungent taste. Its sp. g. is 1·20. Mixed with half its volume of water, it forms a limpid mixture, which becomes opalescent when further diluted, although the glycerine does not separate. It is soluble in ether.

Diacetine is obtained by heating glacial acetic acid with excess of glycerine to 200° for three hours. It is an oil of an agreeable odour, congealing at 40°, miscible with an equal volume of water, but becoming opalescent by further dilution. It is soluble in ether and in benzole.

Triacetine is produced by heating diacetine to 482° for four hours, with fifteen to twenty times its weight of glacial acetic acid. It is a volatile, neutral, odoriferous liquid, of an ethereal and slightly bitter taste, insoluble in water, but very soluble in dilute alcohol. Sp. g. 1·174.

All three acetines are decomposed by alcoholic solution of hydrochloric acid into acetic ether and glycerine.

ACETO-BENZOIC ACID. Formula, $C_{18}H_8O_6 = C_4H_3O_3, C_{14}H_5O_3$. An anhydrous composite acid obtained by treating chloride of othyl with benzoate of soda. The re-action proceeds without the application of heat. The product is purified by washing with water, solution in ether, and final separation of the ether by a gentle heat. Anhydrous aceto-benzoic acid is an oily neutral body, heavier than water, possessing an agreeable vinous odour. It cannot be distilled without decomposition. Boiled with water, it is slowly decomposed into hydrated acetic and benzoic acids; the same decomposition is effected rapidly by solutions of the caustic alkalies, an acetate and a benzoate of the alkali being formed.

ACETO-CINNAMIC ACID. Formula, $C_{22}H_{10}O_6 = C_4H_3O_3, C_{18}H_7O_3$. An anhydrous acid, containing the oxides of the negative radicals othyl and cinnamyl. It is obtained by the action of chloride of othyl upon cinnamate of soda, and in its properties and re-actions closely resembles aceto-benzoic acid.

ACETO-CUMINIC ACID. Formula, $C_{24}H_{14}O_6 = C_4H_3O_3, C_{20}H_{11}O_3$. Formed by the action of chloride of othyl upon cuminate of soda. It is a composite anhydrous acid, closely resembling the aceto-benzoic acid in its properties. Alkalies convert it into acetate and benzoate.

ACETO-SALICYLIC ACID. Formula, $C_{18}H_8O_8 = C_4H_3O_3, C_{14}H_5O_5$. Produced by the action of chloride of othyl upon salicylate of soda. It is a very unstable, composite, anhydrous acid, which is immediately decomposed into acetic and salicylic acids by alkaline solutions.

ACETONE, a derivative of acetic acid. [Ketones.]

ACETONITRYL. [Methyl, Cyanide of.]

ACETONINE ($C_{18}H_{18}N_2$) is formed by the action of gaseous ammonia on acetone. The decomposition is produced by heating the mixture in a sealed tube at a temperature of 212°, $3(C_6H_6O_2) + 2NH_3 = C_{18}H_{18}N_2 + 6HO$. It is an alkaline liquid, with a smell of urine, and is soluble in water, ether, and alcohol. Its combination with hydrochloric acid forms, with bichloride of platinum, a crystalline salt of an orange-yellow colour, insoluble in ether, but soluble in water and in boiling alcohol slightly acidulated with hydrochloric acid. Acetonine stands in the same relation to acetone as amarine to hydride of benzoyl, and is probably a diamine containing three equivalents of the diatomic radical propylene $N_2(C_6H_6)_3$.

Acetonic acid ($2HO, C_{16}H_{14}O_{10}$), is formed when a mixture of acetone, hydrocyanic acid, and hydrochloric acid is heated. $2(C_6H_6O_2) + 2(H, C_2N) + 8HO + 2HCl = 2HO, C_{16}H_{14}O_{10} + 2(NH_4Cl)$. It is soluble in alcohol, ether, and water. It crystallises in prisms, and forms crystallisable salts. Acetonic acid may be regarded as lactic acid, in which two equivalents of hydrogen are replaced by two equivalents of methyl, $C_{12}H_{10}(C_2H_2)_2O_{10}$.

ACETYL. This term has been applied to two distinct hypothetical radicals, viz., first to the group (C_4H_3) which Liebig regarded as the radical of acetic compounds, acetic aldehyde being, according to his view, hydrated oxide of acetyl (C_4H_3O, HO), whilst acetic acid was regarded as the hydrated teroxide of acetyl ($C_4H_3O_3 HO$). Secondly, the name has more recently been applied by Gerhardt to the group ($C_4H_3O_2$) which is regarded by the latter chemist as the true radical of acetic compounds, acetic aldehyde being the hydride of this radical ($C_4H_3O_2, H$), and acetic acid its hydrated oxide ($C_4H_3O_2O, HO$). Williamson proposes the name othyl for the group ($C_4H_3O_2$). [NEGATIVE RADICALS.]

ACETYLAMINE (*Acetylia*). An organic base first obtained by M. Cloëz, and, subsequently, by M. Natanson, in acting upon bibromide of ethylene and bichloride of ethylene with ammonia, and regarded by these chemists as having the formula C_4H_5N. The recent researches of Hofmann prove this body to belong to the family of diamines; according to this chemist it is *diethylene-diamine*, and its formula is $N_2(C_4H_4'')_2H_2$. [DIAMINES.]

ACHROMATIC (from *a without*, and *χρωμα colour*), a term applied to those combinations of lenses used in the best telescopes and microscopes, for preventing the formation of coloured fringes which surround the edges of objects when viewed by means of common instruments. [LIGHT.]

ACIDIMETRY, the process of determining the quantity of real acid contained in a given sample of any acid, and thereby ascertaining its actual or intrinsic value.

There are various methods of accomplishing this: the simplest is by determining the specific gravity of the acid in question. As in most cases the specific gravity of an acid diminishes in regular proportion to the amount of water it contains; the amount of real acid is easily calculated from its density. To facilitate this, tables have been constructed by Dr. Ure and others, in which the specific gravity and the amount of real acid corresponding to it, are placed in parallel columns. These tables will be given in describing the various acids.

The above method however is not always absolutely accurate, and some acids do not admit of its use at all. Advantage has therefore been taken of the fact, that the blue colour of litmus is reddened by acids, while alkalies restore the original colour, to construct a method of estimation which is highly accurate and expeditious. An alkaline solution is prepared of a known strength, and is poured from a graduated tube—an alkalimeter—into an accurately weighed quantity of the acid to be examined (which must be tinged red with litmus) till the point of neutralisation, known by the change from red to blue, is reached. From the number of measures of the test liquid so used it is easy to calculate the quantity of real acid in the sample tested.

A convenient method of preparing the test liquid is to dissolve 530 grains (10 equivalents) of pure dry carbonate of soda—made by fusing the pure bicarbonate—in 10,000 grains of distilled water. The alkalimeter should be made to hold 1000 grain measures, and would thus contain 53 grains, or an equivalent of carbonate of soda. It should be divided into 100 parts, each of which will then contain ·53 of the carbonate. An equivalent of carbonate of soda will exactly neutralise an equivalent of acid, so that 100 grain measures or divisions of the test liquid will represent—

40 grains of sulphuric acid (SO_3), or
49 grains of oil of vitriol (HO, SO_3),
36·5 grains of dry hydrochloric acid (HCl),
54 grains of nitric acid (NO_5), or
63 grains (HO, NO_5),
60 grains of hydrated (glacial) acetic acid ($HO,C_4H_3O_3$), &c., &c.

Supposing, then, that 100 grains of the sample of acid to be tested are weighed, and they require 70 measures of the test liquid, if the acid be sulphuric, then 100 : 40 : : 70 : 28, the amount of real acid in the quantity taken; if hydrochloric, 100 : 36·5 : : 70 : 25·55, and so on. A solution of ammonia may be substituted for that of carbonate of soda, and may be so adjusted that 1000 grain measures shall contain 17 grains of ammonia, which is the case when its specific gravity reaches ·992. It is not easy however to adjust it exactly to such a density; it is better, therefore, when near the convenient strength to estimate the ammonia in a given number of measures of the alkalimeter, by evaporating them to dryness on a water-bath, with an excess of bichloride of platinum. The resulting platinum salt, after being washed on a filter, with a mixture of 2 parts of alcohol with 1 of ether, and carefully dried at 212°, and weighed, contains in 100 parts, 7·624 of ammonia (NH_3).

The strength of the test ammonia may in this way be made to suit the convenience of the operator, and the amount of ammonia in each division being known, the calculation is perfectly simple. Supposing that each measure contains ·20 grains of ammonia, and that 100 weighed grains of the sample of sulphuric acid require 50 measures, the eq. of ammonia, 17 : 40 : : 50 × ·20 : 23·53 grains of sulphuric acid in the quantity taken.

There are other processes for accomplishing the same object. Those used in Alkalimetry, which will be fully described, may, in many cases, be used in a reverse way in Acidimetry, the one process being the reverse of the other. Some acids require special methods of analysis, which will be described under their particular titles.

ACIDS. The acids are a numerous and important class of chemical bodies. As the word acid is, in common language, almost synonymous with *sour*, it might be supposed that the taste of a substance would determine whether it was included among the acids. The term has, however, been so much extended by chemists beyond its original meaning, that some bodies, which are nearly or quite devoid of sourness, are considered as acids because they agree with them in some other qualities. The acids are generally sour; usually, but not universally, they have great affinity for water, and are readily soluble in it: they redden most vegetable blue colours, and combine readily with alkalies and earths, and generally act upon and unite with most metals or their oxides, with great facility, forming compounds which are termed salts. Such are the properties of the greater number of acids; but the last only, namely the power of combining with bases, belongs to them all. Many acids are entirely natural products, some both natural and artificial, while others are altogether the result of chemical agency. They are derived from various sources, and, except in the few particulars above-named, vary greatly in their properties. Thus, under common circumstances of temperature and pressure, some are gaseous in form, as the carbonic acid; others are fluid, as the nitrous, or solid, as the boracic acid; some require water or a base to retain their elements in combination, which is the case with the oxalic acid, while others, as the sulphuric and nitric may exist independently of either. Most acids are colourless, but the chromic is red; some are inodorous, as the sulphuric; others pungent, as the hydrochloric acid; there are acids which are comparatively fixed in the fire, the phosphoric for example; others are volatilised by a more moderate heat, which is the case with the sulphuric acid; whilst those which are pungent to the smell are, to a certain extent, volatile at all temperatures.

Acids occur in all the kingdoms of nature: the margaric acid is of animal origin; the citric and the oxalic acid are products of vegetation; while the chromic and the arsenic acid enter into the composition of certain minerals. In many instances however acids are not exclusively derived from one source, but are sometimes produced by them all, and may be also artificially formed. This is the case with the phosphoric acid, which occurs in animals, plants, and minerals, and is formed whenever phosphorus is burnt in excess of oxygen. The citric acid is produced only by the process of vegetation; but the oxalic acid, also found in plants, may be obtained by chemical agency. The carbonic and the sulphuric acid are very common in mineral bodies, and may also be artificially produced; the former is also one of the results of respiration, combustion, and of animal and vegetable decomposition; and both the carbonic and sulphuric acids may be obtained by combining carbon and sulphur respectively with oxygen. The chromic and the arsenic acid are found only in mineral bodies, but they may be formed by chemical agency; and indeed, except many of the vegetable acids, there are but few which cannot be so prepared.

Soon after Dr. Priestley's celebrated and important discovery of what he called *dephlogisticated air*, in 1774, it was found that several substances, such as sulphur and phosphorus, were converted into acids by combining with this elementary gas. On this account it was assumed, hastily and incorrectly, that all acids contained dephlogisticated air, and derived their acidity from it; on this account the name *oxygen* was given to it, signifying *acid-making*, and it was regarded as the universal acidifying principle; not indeed that it always formed an acid when combined with a body, but that no acid existed without it. It has however since been found that there are acids, the hydrochloric acid for example, which contain no oxygen; and further, it has also been proved, by the brilliant discoveries of Sir H. Davy, that oxygen, by combining with certain elementary bodies, converts them into *alkalies*; a class of substances possessing properties diametrically opposite to those of the acids.

It was therefore considered necessary to divide the acids into *oxyacids*—in which oxygen was supposed to form the acidifying principle; and *hydracids*—in which that principle was due to hydrogen. Hydrated sulphuric acid, HO, SO_3 may be considered as a type of the former class; hydrochloric acid, HCl, of the latter class of acids. When sulphuric or any oxyacid is united to a metallic oxide, the result is a salt in which the water of the acid is replaced by the oxide, forming a so-called *oxysalt*. Thus $HO,SO_3 + NaO = NaO,SO_3 + HO$. When hydrochloric acid or any hydracid is so combined, the hydrogen is replaced, not by the oxide, but by the metal itself. Thus, $HCl + NaO = NaCl + HO$, or chloride of sodium, a salt containing neither oxygen nor hydrogen, and called a *haloid salt* (from ἅλς, the sea), sea-salt being the type of such a compound. Thus the two classes of acids produce in their combinations apparently anomalous results. To obviate this, it was suggested by Sir H. Davy, and has since been supported by Graham, Liebig, and others, that all acids are hydracids, and all salts haloid salts. By this theory, an oxyacid is in all cases a combination of hydrogen with a compound salt-radical. Thus sulphuric acid, instead of being HO, SO_3 is $H +$ the salt radical SO_4, or HSO_4. Nitric acid, not HO,NO_5, but H,NO_6, and so on. In the formation of salts, therefore, the hydrogen of the acid is simply replaced by a metal, as in common salt—

$$NaO + HCl = NaCl + HO.$$
$$NaO + HSO_4 = NaSO_4 + HO.$$
$$NaO + HNO_6 = NaNO_6 + HO.$$

This theory is equally applicable to the organic acids. The formula of acetic acid, $HOC_4H_3O_3$, becomes $H,C_4H_3O_4$; and so with others. Further elucidation of the theories of salts will be found in the article SALTS.

It may be here proper to notice the method adopted by the framers of the French nomenclature, in giving names to different acids. It has been already mentioned, that oxygen was supposed to be the acidifying principle, and it was found that, by combining in different proportions with the same substance, it formed acids of very different properties: but it was not then known that oxygen combined with any one body to form more than two acids. It was, however, proved to unite with sulphur in two different proportions; and in this, and similar cases, the name of the acid which contained least oxygen was made to end in *ous*, and that which contained more in *ic*; thus sulphur*ous* acid contains less oxygen than sulphur*ic* acid.

Cases have, however, occurred during the progress of chemical science, requiring an extension of this principle: an acid has been formed which contains less oxygen combined with sulphur than in the sulphurous, and this is called *hypo*sulphurous acid; another containing more oxygen than the sulphurous, but less than the sulphuric, and this is termed *hypo*sulphuric acid. An acid has also been formed which contains more oxygen than the chloric—this has been called *per*chloric acid.

Acids which form neutral salts by combining with one equivalent of a base are said to be *monobasic*, as the acetic and nitric acids; those which combine with two equivalents of base are said to be *bibasic*, as tartaric and pyrophosphoric acids, whilst those which require three equivalents of base to form a neutral salt are termed *tribasic* acids. [CHEMICAL NOMENCLATURE.]

The means adopted for preparing the acids, whether from the natural compounds which contain them, or by the direct combination of their component parts, are almost as various as the acids themselves. For an account of the processes employed in obtaining them, and of the numerous and important purposes to which the acids are applied in medicine, science, and the arts, or for domestic uses, we refer the reader to each particular acid. Although in the course of the present work some acids of minor importance will occasionally be mentioned, the following are those which, as being used either in scientific researches, in medicine, or the arts, will be more particularly treated of in their respective places:—

ACIDS.

Acetic.	Chlorochromic.	Hyposulphuric.	Pyroligneous.
Aconitic.	Chlorosulphuric.	Hyposulphurous.	Pyrophosphoric.
Acrylic.	Cholalic.	Iodic.	Pyroracemic.
Adipic.	Choleic.	Lactic.	Pyrotartaric.
Alizaric.	Cholic.	Lauric.	Racemic.
Allanturic.	Chromic.	Malic.	Rhodizonic.
Alloxanic.	Cinnamic.	Margaric.	Ruberythric.
Amidobenzoic.	Citric.	Meconic.	Saccharic.
Amygdalic.	Crenic.	Mellitic.	Salicylic.
Angelic.	Croconic.	Mesoxalic.	Sebacic.
Anilic.	Cyanic.	Metastannic.	Selenic.
Anisic.	Cyanuric.	Molybdic.	Selenious.
Anthranilic.	Dialuric.	Mucic.	Silicic.
Antimonic.	Dinitroethylic.	Myristic.	Sinapic.
Antimonious.	Dithionic.	Nitric.	Stannic.
Apocrenic.	Erythric.	Nitromuriatic.	Stearic.
Arsenic.	Ferridcyanic.	Œnanthic.	Suberic.
Arsenious.	Ferrocyanic.	Œnanthylic.	Succinic.
Aspartic.	Formic.	Oleic.	Sulphacetic.
Benzoic	Fulminic.	Osmic.	Sulphantimonic.
Bismuthic.	Fulminuric.	Oxalic.	Sulphantimonious.
Boracic.	Gallic.	Oxalovinic.	Sulpharsenic.
Borofluoric.	Glucic.	Oxamic.	Sulpharsenious.
Bromic.	Glycolic.	Palmitic.	Sulphovinic.
Butyric.	Hippuric.	Parabanic.	Sulphuric.
Camphoric.	Homolactic.	Pectic.	Sulphurous.
Capric.	Humic.	Pelargonic.	Tannic.
Caproic.	Hydriodic.	Pentathionic.	Tartaric.
Caprylic.	Hydrobromic.	Perchloric.	Telluric.
Carbamic.	Hydrochloric.	Periodic.	Tellurous.
Carbazotic.	Hydrocyanic.	Permanganic.	Tetrathionic.
Carbolic.	Hydrofluoric.	Phosphoric.	Titanic.
Carbonic.	Hydrofluosilicic.	Phosphorous.	Trichoracetic.
Carbovinic.	Hydrosulphocyanic.	Phosphovinic.	Tungstic.
Carminic.	Hydrosulphuric.	Phthalic.	Ulmic.
Cerotic.	Hypochlorous.	Picric.	Uric.
Chloracetic.	Hyponitric.	Propionic.	Valeric.
Chloric.	Hyponitrous.	Prussic.	Xanthic.
Chlorocarbonic.	Hypophosphorous.	Pyrogallic.	

ACONITIC ACID, $3HO, C_{12}H_3O_9$ (EQUISETIC ACID; CITRIDIC ACID), exists naturally in *Aconitum napellus*, *Delphinium consolida*, and *Equisetum fluviatile*, but is most easily obtained by the action of heat on citric acid. Crystallised citric acid is submitted to distillation until oily streaks appear in the receiver. The residue contains aconitic acid, which is dissolved out by absolute alcohol, etherified by hydrochloric acid, and then obtained as a potash salt by the action of caustic potash upon the aconitic ether. Aconitic acid is tribasic; it crystallises indistinctly. At a temperature of about 320° it is decomposed into a crystalline substance called *itaconic acid*, and an oily liquid called *citraconic acid*, both having the formula $2HO,C_{10}H_4O_6$.

ACONITINE ($C_{60}H_{47}NO_{14}$). An alkaloid existing in *Aconitum napellus*, and other varieties of the aconite. It crystallises from a solution in dilute alcohol in white grains; it is also often obtained in the state of a vitreous, transparent, compact mass. It is inodorous, but intensely bitter and acrid. It is extremely poisonous; one 50th of a grain is sufficient to kill a sparrow in a few minutes, and a tenth of a grain instantly. It is very slightly soluble in cold water, unalterable in the air, very fusible, and not volatile; its alkaline re-action is very distinctly marked; it requires 50 parts of boiling water to dissolve it, and the solution does not become turbid on cooling; it is very soluble in alcohol, and to a less extent in ether. Aconitine forms perfectly neutral salts. Those which have been examined crystallise with great difficulty, and dry in the state of a bitter gummy mass, which is acrid and very poisonous. Fuming nitric acid dissolves them without colour; moistened with concentrated sulphuric acid, they assume a colour, at first yellow and then reddish violet. Infusion of galls produces in their solution an abundant precipitate of white flocculi, and solution of iodine a kermes-coloured precipitate. Aconitine is said by Geiger and Hesse to dilate the pupil, but that obtained by Dr. Turnbull contracts it; and Dr. Pereira mentions the power of contracting the pupil as one of the distinctive properties of the alkaloid. When applied to the skin in very minute quantity, it produces a sensation of intense heat and numbness. It is used medicinally in the form of ointment, and is of great use in severe neuralgia, and rheumatic affections.

ACONI'TUM (*Monkshood* or *Wolfsbane*), *Medical Properties of*.—The botanical characters of this genus of Ranunculaceous plants have been already given. [NAT. HIST. DIV., vol. i. p. 58.] Which species merits the preference as a medicinal agent is a greatly controverted point. The London and Dublin Pharmacopœias, following the notions of Decandolle as to the identity of his *Aconitum paniculatum*, var. *γ Störkianum*, with the *A. napellus* officinalis, figured by Störk in his 'Libellus de Stramonio, Hyoscyamio, Aconito,' Vindobon. 1762, have given that as the officinal one, while the Edinburgh College has retained the common *A. napellus*. The preponderance of evidence and good sense is in favour of the latter, as, besides the almost impossibility of procuring the plant indicated by the two former, since it is only a rare inmate of botanic gardens, it is substituting a confessedly less potent for a more potent plant. The 'London Pharmacopœia' has restored in the edition of 1851, the *A. napellus*, as the officinal plant. But besides this, two other species are grown at the physic-gardens at Mitcham, whence the London market is chiefly supplied. One, a party-coloured sort, having white flowers with a little blue in them: perhaps intended for the *A. paniculatum* (Decandolle); another *A. exaltatum* (Bernhardi), synonymous with *A. decorum* (Reichenbach). This, if found equally potent as the common *A. napellus*, has much advantage. Its tall size supplies more leaves, and as it does not flower till much later in the year (September) its leaves retain their virtues till the flowers begin to fade—and can yield a supply of fresh leaves, when these are wanted, long after the common species have become inert. *A. ferox* is now largely imported from India, in a dry state, to yield aconitine, of which it contains three times as much as the European species. The aconite of Störk, whatever species he used, was a plant possessed of great acrimony, while *A. paniculatum* has scarcely a perceptibly acrid taste. The officinal parts are the root and leaves. But the seeds might be added with propriety. Every part of the plant has a narcotico-acrid property. The live plant has little of the virose repulsive odour common to poisonous vegetables; nevertheless very sensitive individuals, by merely smelling the flowers, have fainted, and had dimness of vision for some days, and handling the fresh plant has occasioned tremblings and faintness. Honey collected from these flowers has caused severe suffering and even death. In making the essential extract, and in procuring the alkaloid aconitine, the vapours have powerfully affected the operators; hence much care is required on their part. A small piece of the leaf, root, or a single seed, if chewed, causes a feeling of tingling, followed by numbness of the lips and tongue, which lasts for hours. A greater portion causes these sensations in the palate and throat, where in larger or poisonous doses a choking sensation is felt. The resemblance of many aconites, especially before flowering, to several umbelliferous plants in common use, such as celery, lovage, masterwort, &c., proves a frequent source of poisoning by them; a calamity further augmented by the inconsiderate practice of giving ignorant persons portions of the leaves to chew, or as a kind of parsley. (See a melancholy case of poisoning by *Aconitum neomontanum*, in Johnson's 'Medico-Chirurg. Review,' vol. lxi. p. 264.) Such unprincipled practices cannot be too severely reprobated. No complete analysis of the root or leaves of the *A. napellus* has hitherto been published, though Pallas analysed the root of *A. lycoctonum* and Bucholz the leaves of *A. medium*, Schrad. It is probable that all the species contain similar constituents, differing only in degree, the most powerful being the *A. ferox* (Wallich, 'Pl. Asiat. Rariores,' i. t. 41) or Bisk of Northern India. The most important are the alkaloid aconitine, aconitic acid, a fatty oil, and perhaps a volatile acrid principle. The latter probably results from the decomposition of aconitine by the action of heat. Almost all ranunculaceous plants have an acrid principle, which is very easily driven off by heat. Much care is therefore requisite in drying the root or leaves of aconite not to apply too high a temperature. The same precaution is required in forming the extract or inspissating the juice. A knowledge of this fact leads to the most convenient and effectual antidote in cases of poisoning by these plants, viz., causing the patient to drink very warm water till vomiting is excited. Linnæus saw aconite disarmed of its virulence, so that it could be used as a pot-herb, by merely boiling it, and adding a little fat or butter. (Linnæus, 'Flora Lapponica,' p. 187, ed. Lond. 1792.)

The fatty oil is destructive of the sensibility of any part to which it is applied, but whether from inherent powers or from having aconitina dissolved in it is yet unknown. The alkaloid is regarded as the efficient principle when aconite is used medicinally. The forms of administration are various. Powder is objectionable from the variable degree of power. This further varies with the period when the leaves are collected. The best time to gather them is immediately before the flowers wither, as when the seeds advance to maturity the acrimony of the leaves rapidly diminishes. (Christison.) When the seeds are intended to be collected, this should be done just before they are perfectly ripe. The root should be taken up before the flowers expand; it must be carefully, yet speedily dried, at a very low temperature, otherwise it soon becomes mouldy and its activity is impaired, while a high temperature quite dissipates its valuable properties. The watery extract is a worthless preparation; and the inspissated juice of the 'London Pharmacopœia,' improperly termed an extract, is also objectionable. All these anomalies, and the diversity of strength of the different preparations enjoined by the different pharmacopœias of London, Edinburgh, and Dublin, from the existence of which, serious consequences often result, will in future be avoided, by the publication of the 'National Pharmacopœia,' ordered to be prepared under the new Medical Bill. Besides the officinal preparations, various popular ones exist. Of the scientific ones, Dr. Fleming's tincture is the best. It requires great care in its use. An excise officer lost his life, from merely tasting it ('Journal of Pharmaceutical Society,' vol. xi. p. 237). A spurious aconitine is prepared in France, and imported into this country. It is devoid of the valuable properties of the genuine, the high price of which offers too great a temptation to fraud. The best forms are either an alcoholic extract of the leaves, or an alcoholic tincture of the root made by displacement. The inactivity of the watery extract and inspissated juice has led to statements in some popular treatises that it may be given in the dose of twenty grains, a quantity which would prove fatal when the extract is prepared with alcohol. Of this latter it is rare that two grains can be given with safety: a quarter of a grain is sufficient to begin with. Possessing narcotico-acrid properties, the action of aconite on the human frame is different according to the quantity used. In small medicinal doses its most obvious action is purely local; in larger, its action is both local and remote. Thus a small portion chewed produces an immediate action, tingling, followed by numbness of the lips and tongue; increased secretion of saliva also occurs. Minute doses taken into the stomach cause augmented secretion both of the mucous membrane and of the glands in the vicinity, the secretion of the liver is often markedly increased; while tingling of the extremities, with heat, is often felt, and either perspiration or increased action of the kidneys. The effect on the pupil is variously stated. Geiger affirms that aconitine produces dilatation of the pupil, Dr. Pereira most positively asserts, in his Materia Medica, that the external application of it produces contraction; while in his experiments with the extract of the *Aconitum ferox* (recorded in 'Edinb. Journ. of Natural and Geograph. Science,' July 1830, p. 235) he distinctly states that while the animal continued alive the pupils were 'much dilated,' contraction taking place only after the animal was apparently dead. Large doses cause redness and inflammation of the parts brought in contact with it; but the intellectual powers do not seem impaired by it, even when a fatal result occurs. Sir B. Brodie thinks that it occasions death by destroying the functions of the brain. ('Phil. Trans.' 1818, p. 186.) For this effect he does not consider absorption necessary; while Dr. Pereira concludes from his experiments, that the intensity of its remote action on the nervous system is in proportion to the absorbing powers of the part to which it is applied ('Edinb. Jour.' p. 242). The susceptibility of the heart to galvanic agents is greatly impaired by it.

When first introduced into medical practice it was recommended in many diseases; but it is now almost entirely restricted to painful affections of the nerves, and to rheumatic complaints, particularly when they are complicated with syphilis. For nervous affections it is more used externally than internally, but this last mode is to be commended at the same time. An ointment is formed with one or two grains of the aconitine to one drachm of axunge. A small portion of this is to be applied frequently to the part affected. An eruption sometimes appears, especially if the ointment be strong. The internal use of aconitine is scarcely to be advised, one-fiftieth of a grain having endangered the life of an adult. The very high price of this article is an obstacle to its extensive employment; but ingenious chemists are endeavouring to simplify the process of extracting it. To obtain it perfectly pure it is almost essential to use sulphuric ether in the preparation of it, which necessarily increases the expense. The alcoholic tincture or extract is of great service in chronic rheumatism, and even in some cases of acute rheumatism.

Should poisoning occur, no time is to be lost, as it has proved fatal in one hour after being eaten instead of horseradish, at Bristol ('Jour. of Pharmaceutical Society,' vol. xiii. p. 294). Animal charcoal has been recommended as an antidote. But even if really useful, it is only serviceable when quite freshly prepared, in which state it is rarely to be had promptly. The best mode of proceeding is—as soon as it has been ascertained that Monkshood has been taken, if the root or leaves have been eaten—to endeavour to empty the stomach as quickly as possible. Warm water alone, or with flour of mustard in it, will generally effect this; or a stomach pump, if at hand, may be used. Perhaps magnesia diffused through the water may be useful. But 'abundance of very warm water' is good alone. Afterwards hartshorn, properly diluted, tincture of cardamoms or brandy may be given. The patient should be kept walking, if possible. Should inflammation ensue, venesection may be needed.

ACOUSTICS is sometimes divided into the science of hearing (from ἀκούω, *to hear*), and that of *sounding* or PHONICS (from φωνή, *sound*). It is not necessary to attempt to define what sound is, or to dwell on the fact that some sounds differ only in intensity or loudness, as the reports of a cannon and a musket; others in musical pitch, as two notes of the same instrument; others again in character or tone, or, as the French call it, *timbre*, such as the same note sounded on a flute and a trumpet. These differences being understood, we proceed to inquire by what agency these different sounds are conveyed to the ear; in what manner the ear is acted upon by sounds of different loudness, tone, and character; and how far we can explain the remarkable fact that we can hear and distinguish, at the same time, almost any number of different sounds. Unfortunately, our knowledge is limited by the nature of the question, which requires the improvement of one of the most difficult branches of mathematical analysis; and by our very imperfect knowledge of the constitution of matter, and the effect which the putting in motion of some particles of a body has upon the other particles. Strictly speaking, we ought to say, that sound has no existence except in the mind of the hearer; but, in accordance with common phraseology, we shall speak of a body as *sounding* when it is in that state in which it would produce the impression of sound, if the proper medium were placed between it and the ear.

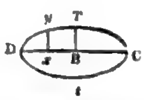
No body can produce a sound, as we know from observation, unless its parts be put into rapid motion. We have evidence of this in a tuning fork, the string of a musical instrument, the parchment-head of a drum, &c. Neither will any sound be perceived unless there is a continual supply of solid or fluid matter, possessed of a moderate degree of elasticity, between it and the ear. Thus, a bell, when rung in the exhausted receiver of an air-pump, yields hardly any sound; and the small portion which it does give may be destroyed or materially diminished by lining the receiver with cotton or wool; or still better, by exhausting the receiver as much as the air-pump will allow, then filling it up with pure hydrogen gas and again exhausting. The air is generally the medium through which sound is conveyed; but only because this is most commonly the one with which the *membrana tympani* or membrane of the drum of the ear is in direct communication. A bell rung under water has been distinctly heard by M. Colladon across the whole breadth of the lake of Geneva, a distance of 9 miles, the sound being observed to pass through the water with a velocity of 4708 feet per second; those who work in one shaft of a mine can often distinctly hear the sound of the pickaxe in another shaft through the solid rock; and persons wholly deaf, who therefore are not at all affected through the ear, have received pleasure from music, by placing their hands upon a shutter or other solid body near the instruments. Biot's experiments, too, have shown some very curious results of the varying velocity of sound for different media. He fixed a bell at the end of an iron tube of about 3120 feet in length, and he found that the sound of the bell was double as heard at the other end, the first sound being transmitted through the metal, and the second through the column of air in its interior. He also found that the slightest whisper at one end was distinctly communicated to the other. To this fact he added the observation, that the well-known double report of a musket is owing to the same cause, the sound being unequally carried through the air and the vapour floating in it. In the following remarks we will confine our attention to what takes place in air during the production of sound.

The body of air which surrounds us produces no sound if it be all moved together, that is, if the velocity of all its particles be the same: the highest wind makes no noise except when it is forced against some obstacle; but the sound of a cannon is heard in whatever direction the wind may blow: it may also be remarked, that the strongest band of music does not produce any sensible wind in any direction. It is therefore to some other kind of motion that we must look for the agent of sound, and the manner in which sonorous bodies move immediately points it out. If a tuning-fork or string be struck, a rapid succession of vibrations is the consequence, which, as we shall see, causes the particles of air to vibrate in a similar manner. We find, moreover, that in order to produce a note, there must be not only a succession, but a *rapid* succession, of vibrations. Now, experiments show that the ear is not capable of receiving the impression which we call *sound*, unless the particles of air in contact with it vibrate at least 30 times in a second. The vibration produced in the particles of air by a sonorous body may be distinctly proved by the following experiment. Let a tuning-fork be sounded, and while yet in vibration, let it be stopped by the finger. A sensation will be felt for an instant, for which we have no name in our language, arising from the prong of the fork rapidly, but gently, striking the finger, and very different from that which is produced by merely touching the fork when at rest. Now, blow into a common flute, and at the same time stop gently two or three of the higher holes. The same sort of sensation, though in a much smaller degree, will be felt on that part of the fingers' ends which is in communication with the interior air. For this purpose the fingers should be warm, but if the observer be not used to the instrument, the effect is made more certain by tuning the string of a violoncello to the note which is to be fingered on the flute, and then sounding the former strongly, while the latter is held over it, with the fingers placed as before. The column of air in the flute will be made to vibrate by the motions of the string, forming a case of what is called *sympathetic vibration*. That any very violent and sudden noise produces a concussion in the air even farther than the sound can be heard, is proved by the fact, that the explosion of a large powder-mill will shake the windows in their frames for nearly twenty miles around.

We now proceed to describe, as far as can be simply done, the motion which takes place in the air when the impression of sound is communicated; and here we stop to explain a method which may be adopted in many cases, of making the eye assist the reason. Suppose we wish to register what takes place in the vibration of a spring, of which the position of rest is A B (*fig.* 1), but which, having been set in motion, passes through all the positions between A C and A D. The

Fig. 1.

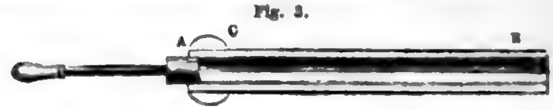
Fig. 2.



spring being drawn aside by the finger or other disturbing cause to A C, and then released, the elasticity of the metal makes continued efforts to restore it to its first position A B, by which it is made to move, and with continual accession to its velocity, until it actually does arrive at A B, where, if the velocity were suddenly destroyed, it would remain at rest. But the velocity still continuing, the spring continues to move towards A D, with a change of circumstances, inasmuch as the elasticity, now opposing its motion, gradually destroys the velocity by the same steps as it was before gradually created; so that when the spring comes to A D, it will be again at rest, but will not continue so, since the elasticity will cause the same phenomena to be repeated, and the spring will move back again towards A C. But for friction and the resistance of the air it would again reach A C; it does not, however, get so far, owing to these causes, which always diminish, and never increase, velocity. This alternation will go on until the spring is reduced to a state of rest. Similar phenomena occur in the motion of a pendulum, of the string of a harpsichord, and generally, wherever small vibrations are excited in a body, which remove it, but not much, from its position of rest. We might, perhaps, conclude, that each successive oscillation is performed in a shorter time than the preceding, seeing that a less space is described by the spring. But this is not the fact; it can be observed, as well as demonstrated, that the oscillations which take place before a body recovers the effects of a small disturbance and resumes the state of rest, are severally performed, if not in the same time, yet so nearly in the same time, that the difference may be entirely neglected in most practical applications. Such being the case, we may omit the effects of friction and resistance, so far as the *time* of vibration is concerned, and consider the spring as describing exactly the same path in each successive vibration. Let D C (*fig.* 2) be the line described by the top of the spring, which we may call a straight line, since it is very nearly so, and while the spring moves from D to C, imagine a curve D y C to be drawn, in such a way that, the spring being at x, the perpendicular $x\,y$ is the rate per second at which the top of the spring is then moving. A little attention will show that the curve which we have drawn represents the various changes of motion just alluded to: thus T B, the greatest perpendicular, is over the point B, where the spring moves fastest; and at D and C there is no perpendicular, because the spring comes to rest when it reaches those points. During the return from C to D, in which the motion is the same, but in a contrary direction, let a similar branch C t D be drawn, on the other side of C D. We will call the whole curve D T C t D the *type* of the double vibration of the spring, the two branches being the types of its two halves. Now, suppose a column of air inclosed in a thin tube A B (*fig.* 3), which is indefinitely extended towards B, but closed at A by a piston which can be moved backwards and forwards from A to C, and from C to A, after the manner of a spring, the type of its motion being represented by the curves on A C. And first let the piston be pushed forward from A to C. If the air were solid, we should say that a column of air A C in length would be pushed out of the end B of the tube in the time in which the piston is driven in, but we certainly can have no notion that such an effect would be produced upon a column of elastic fluid like the air. Experiment, as well as mathematical demonstration, show us that though every particle of the fluid will finally be

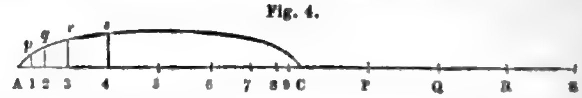
put in motion, yet that those particles which are nearer the disturbing piston receive their first impression sooner than those which are more

Fig. 3.



distant; and we find that this successive *propagation*, as it is called, of the disturbance, goes on *uniformly* at the rate of about 1125 feet in a second, the temperature being 62° of Fahrenheit; for example, a second must elapse before those particles, which are 1125 feet distant from A, will have their first news, so to speak, of what is going on at A, and in the same proportion for other distances. It is also shown that the velocity of communication is not affected by the greater or less degree of violence with which the air is struck, but remains the same for every sort of disturbance. With such a velocity, we may see that the column of air made up of all the particles which feel, or have felt, the effects of the disturbance, must be very long when compared with A C, the extent of an almost insensible vibration; so that it will lead to no sensible error if we suppose that the effect of the piston at every point of its course is propagated instantaneously to C, and *thence* only, with the velocity of 1125 feet per second. We will now consider what this effect is. Divide the whole length A C, *fig.* 4, into a large number of very small parts, *described in equal times*, and instead of the piston moving continuously, and with imperceptible changes of velocity, along A C, let it move by starts from each point to the next, with the proper increase or decrease of velocity. In the figure we have divided A C into ten parts, but the same reasoning applies to any greater number. We have much enlarged A C (*fig.* 4), to give room for the figure: the reader

Fig. 4.



may help his ideas by supposing that A C is viewed through a powerful microscope, and the rest of the tube by the naked eye. Whatever may be the common time of moving through each of the parts A 1, 1 2, &c., the portions of the column affected by the starts of the piston will be of the same length, and each will be as much of 1125 feet as the time of each start is of one second. Set off the lengths C P, P Q, Q R, &c., each equal to this length, and for the present let us agree to call the common time in which the piston starts through A 1, 1 2, &c., an *instant*. The reader must bear in mind throughout that we intend to carry the supposition of dividing A C into parts to its utmost limit, by which we shall have to suppose C P, P Q, &c., to be very small, though still great when compared with A 1, 1 2, &c. We also think it right to repeat, that all the figure on the left of C is immensely magnified, and that the propagation is supposed to be instantaneous from 1, 2, &c., to C. In the first *instant*, the piston moves through A 1, with the velocity p 1 per second, and forces the column of air A 1 into C P, which therefore has its density increased, or is compressed, the air which was held in C P and A 1 together being now confined in C P. As the propagation has not travelled farther than P, the effect is just the same as if there had been a solid obstacle at P during the first instant. The portion C P is then compressed, strictly speaking, *unequally*; that is, the parts near to C are more compressed than those near to P; but on account of the small length of C P, and the rapidity of the transmission, we may suppose all the parts to be equally compressed. Again, the particles near C begin to move towards P, and for a similar reason we may suppose the velocities of all the particles to be the same; this velocity being that of A during the first instant. The reader must not confound the absolute velocity of the several particles, which is always small, with the rate at which they transmit their velocities and compressions, which is very great. We will use the phrase that the portion C P has received its *first compression*. If the piston were stopped at the end of the first instant, the whole effect upon C P would be transferred to P Q in the second instant, both as to compression and velocity, and the particles of C P would return to their first state, and receive no further modification. But in the second instant, the portion C P receives its *second compression*, which is greater than the first, since a column 1 2 longer than A 1 is forced into it. Similarly, the velocity is increased, being 2 q per second instead of 1 p. If the spring were then stopped, the third instant would see the portion P Q transmit its velocity and compression to Q R, C P to P Q, and C P would resume its natural state. But in this instant, C P receives its third compression, which is greater than the former two, and the same process goes on, each portion transmitting its velocity and compression to the *succeeding* one, receiving in its turn more than it parted with, from the *preceding*. This continues until the piston has reached the middle point of A C, after which the compression of C P still continues, but becomes less and less in successive instants, because 5 6, 6 7, &c., down to 9 C, decrease in length, in the same way as A 1, 1 2, &c., increased. When the piston begins to return through C 9, in the eleventh instant, the portion C P receives its *first rarefaction*; for the air in C P now occupies C P and C 9; the particles in C P therefore move towards C instead of from it, and the preceding modifications are successively repeated in *quantity*, but changed into their contraries; that is, each portion undergoes successive rarefactions, equal in amount to the former condensations, and the particles move *towards* C with the same velocities which they formerly had *from* C. This continues until the piston reaches A again, after which the same phenomena recommence in the same order. Thus it appears that the absolute velocity of each particle is in the direction of the propagation so long as it is compressed; but in the contrary direction, when it is rarefied, and that each particle, during the progress of a double series of compressions and rarefactions, moves forward in the direction of propagation, and back again to its former place, where it rests, unless a third vibration follow the first two. When we talk of the compression of a particle, we mean that it is nearer the succeeding particle than it would have been in its natural state; and *vice versâ* for rarefaction. We may represent these phenomena in the following table, which, to save room, is made on the supposition that A C was divided into four parts, and might be equally well constructed if the number of parts into which A C was divided had been greater. The numbers in the top horizontal line are the successive portions of the tube, those in the left vertical column the successive instants of time, and under any portion of the tube, opposite to any instant of time, will be found the state in which that portion of the tube is at that instant of time,—1 denoting its first compression, 1′ its first rarefaction; these latter numbers recommencing when a complete cycle of changes is finished. The blanks denote that the effect has not yet reached the corresponding particles.

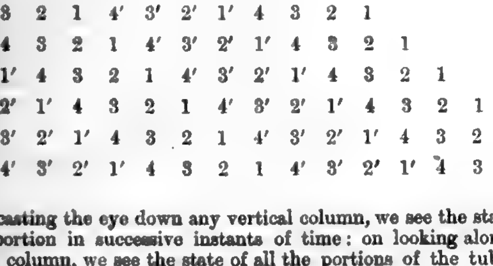
On casting the eye down any vertical column, we see the state of the same portion in successive instants of time: on looking along a horizontal column, we see the state of all the portions of the tube at the same instant, as far as the effect has reached them. In the latter case, we see that all the successive states are continually repeated, in such a way, that whatever states two portions may be in, the intermediate portions have all the intermediate states. There is also at the beginning an unfinished series in process of formation. If we look down a column, we see that any one particle successively undergoes the different states, from the moment when the effect first reaches it. We shall now suppose the division of A C to go on without end, and examine the final result. The different states of compression or rarefaction will then become more and more numerous, but the difference of quantity between each and its preceding will become less and less, so that when we at last give to the piston a *continuous* or gradually increasing and decreasing velocity, we must also suppose a continuous or gradually increasing and decreasing compression or rarefaction of the air in the tube. This being premised, we return to the figure, and construct the *type* of the motion of the piston, both backwards and forwards, and also the *type* of the state in which the particles of air actually are for two or three several positions of the spring; as in the figure below, which we proceed to explain. (*Fig.* 5.)

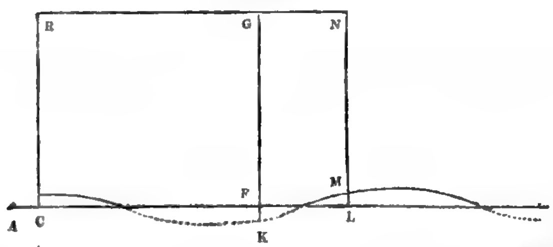
Fig. 5.



In *fig.* 5 (1) the piston has travelled from A to the small perpendicular, through something more than a quarter of a vibration: the first disturbance has reached D, and the curve D K is the *type* of the state of each particle as to velocity; that is, the perpendicular F G is the rate per second at which the particle F is moving from C, and the same for every other perpendicular.

If the piston be performing its third complete vibration, or its second vibration *forwards*, there will have been a preceding series of compressions and rarefactions propagated onwards, as in *fig.* 5 (1). In *fig.* 5 (2), a vibration forwards has been completed; the curve on C D now represents a complete undulation, as far as the compressions are concerned. In *fig.* 5 (3), the return of the piston has commenced, and the particles between C and D are rarefied, and moving towards C; this we explain by placing the *type* beneath the tube, and dotting the curve; F G expressing the velocity per second of the particle F towards C. The length of the whole wave C D is easily calculated. If, for example, the single vibrations of the piston are made in $\frac{1}{100}$ of a second, the first impulse will have travelled through one hundredth part of 1125 feet, or $11\frac{1}{4}$ feet. This is the length of C D, in *fig.* 5 (2). The complete series of compressions is called a *wave of compression;* and that of rarefactions a *wave of rarefaction.* And the same type which represents to the eye the velocities of the various particles, will also serve to represent the degrees of compression or rarefaction. For those particles which are moving quickest from C are most compressed, and those which move quickest towards C are most rarefied. In returning to *fig.* 4, we see that A 1, 1 2, 2 3, &c., are spaces described in equal times, and are therefore in the same proportions as the velocities, that is, as 1 *p*, 2 *q*, 3 *r*, &c. But these spaces, in the preceding explanation, are proportional to the degrees of condensation; these latter then are proportional to the velocities. If, then, we suppose the series of compressions and rarefactions to have gone on for some time, and an unfinished wave of compression to have been formed at the instant we are considering, we may represent the whole state of the particles in the tube at that instant by the following figure (*fig.* 6):—R G N is a line parallel to the tube, and therefore G F is of the same length for all positions of F. It is to be made 1125 feet in length. Its use depends upon the following proposition:—That in the simple undulation which we are now considering, so long as the disturbance is small, the velocity of any particle bears to the *velocity of propagation* (two very distinct things, as we have before observed) the same proportion as the change in the density bears to the density of undisturbed air. This follows from the investigation attached to *fig.* 4: for, in the fourth instant for example, the column 3 4 of air is forced into C P, and 3 4 and C P being spaces described in equal

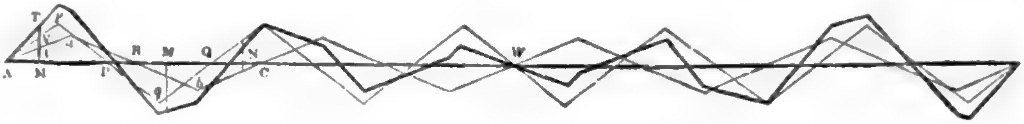
Fig. 6.



times with velocities 4 *s* and 1125 feet per second, are spaces proportional to these velocities. And the compression will be the same if we increase C P in any proportion, provided we increase the quantity of air forced into it in the same proportion. A similar proposition holds for rarefactions. Or, in other words, F K being the velocity with which the particle at F is moving *towards* C, the rarefaction of the particles at F is that which would be obtained by allowing the air naturally contained in a tube G F, 1125 feet long, to expand into the length G K. Similarly, the compression at L is that which would be obtained by compressing the air in a tube N L into the shorter tube N M. If we wish to see the state of these particles at any succeeding instant, let the *curvilinear* part of the figure travel uniformly forward at the rate of 1125 feet per second, new curves being continually formed and finished at C: we shall thus have the state of the whole tube at any succeeding moment. Before proceeding to apply this explanation to the phenomena of sound, we must see what will take place if the tube be agitated by several different undulations at once.

All readers, however little acquainted with Mechanics, are aware, that if a body be impressed by two forces in the same direction, it will proceed with the sum of the velocities produced by the two forces; and with the difference of the velocities, if the forces act in contrary directions, the motion in the latter case being in the direction of the greater of the forces. Hence, if there be different undulations excited in the same column of air, the velocities of each particle will be made up of the *sum* or *difference* of those which it would have received from each undulation, had each acted alone; the *sum* when it would have been compressed by both, or rarefied by both, and the *difference* when it would have been compressed by one and rarefied by the other. And the compressions or rarefactions being proportional to the velocities, a similar proposition will hold of them. We have represented in *fig.* 7, the state in which a column of air would be at a given instant from two different waves, the types of which are drawn, and the broad line is the type of their united effects. We know that any two lengths are either in the proportion of two whole numbers, or if not, two whole numbers can be found, which are as nearly proportional to them as we please. We have, to take a simple case, drawn the lengths of the waves in the proportion of 5 to 4. (*Fig.* 7.) The types of the waves are different portions of straight lines, one whole condensation and rarefaction taking place, as indicated by A a B b C in the first, and by A p P q Q in the second. We suppose the waves to commence together. This supposition, of the condensation and rarefaction proceeding in such a way that their types shall be parts of straight lines, is not to be obtained in practice, since, as we have seen,

Fig 7.



such motion as that of a spring, and (we may add) of a string or of a drum, would produce regular curves. But it is as allowable in illustrating the effects of combined undulations as any other; and if, moreover, we round the corners of the types of the single waves, thus making them present an appearance similar to that in the preceding figures, a slight rounding of the corners of the broad line will show sufficiently well what the combined wave would have been, if the preceding figures had been rounded. And the supposition of rectilinear types facilitates the drawing of such figures (which we would recommend to our readers), since, as they will observe, the type of the combined wave consists also of portions of straight lines which break off only when the type of one of the single waves changes from one line to another. The general rule for forming the broad line, derived from a preceding observation, is—let the perpendicular or ordinate [ABSCISSA] be the *sum* of the perpendiculars of the types of the waves, when they fall on the *same* side of A P, and the difference when they fall on different sides; observing, in the latter case, to let the broad line fall on the side of that wave which has the greatest perpendicular. Thus at the first M, M T is the sum of M U and M V, and particles at M are in a greater state of compression than the first wave would give them, which arises from the second; similarly at the second M there is an increase of rarefaction. At N, the air is compressed by one wave, and rarefied by the other, but more compressed than rarefied. At P, B, Q, C, &c., where one of the waves causes neither compression nor rarefaction, the broad line coincides with the other wave.

On looking at the figure thus produced, we see—

1. That it is composed of a cycle of successive compressions and rarefactions, in which, however, the rarefactions differ in kind from the preceding compressions; so that we must not give the term *wave* to each set of compressions or rarefactions, as we reserve this word to denote cycles of changes, which are followed by similar cycles of contrary changes.

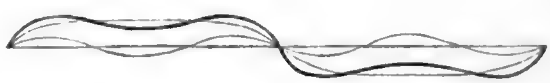
2. That when the lengths of two waves are as five and four, four of the first will be as long as five of the second; so that the waves recommence together at W, but not exactly as before, the wave of condensation from the first being accompanied by the wave of rarefaction from the second. This difference, however, is not found at the end of the second similar cycle of four and five; so that after eight of the first waves, corresponding to ten of the second, the combined wave begins again to have the same form as at first.

3. The complete cycle denoted by the broad line may be divided into two, joining at W; in the second of which a series of rarefactions is found similar to every series of compressions in the first, and *vice versâ*. We may, therefore, give the name of wave to the part of the broad line intercepted between A and W, consistently with our definition of this word.

4. If the waves had not begun together, a wave would have resulted of the same length as the preceding, if we began at any point where the compression from one was exactly compensated by the rarefaction from the other.

5. If both waves had been of the same length, the resulting wave would have had that length; or if the first wave had been contained an exact number of times in the second, the resulting wave would have been of the length of the second. We subjoin a cut (*fig.* 8) representing a wave contained three times in another wave, and the resulting wave.

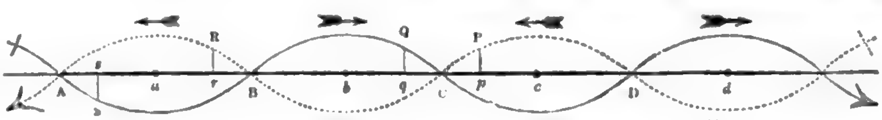
Fig. 8.



We have hitherto considered combined undulations as propagated in the same direction: let us now take two waves of equal lengths propagated in opposite directions, rising, as we may suppose, from two pistons, one at each end of the tube. After a certain time, depending on the length of the tube, two waves will meet, by which we mean that the particles will begin to be affected by the motion of both pistons, and the manner in which the joint effect is represented is the same as before, though the phenomena are very different. In the former case, having represented the resulting wave at one instant, we could trace the change of state throughout every particle of the fluid, by supposing the type of that resulting wave, or a succession of such types, to move along the tube at the rate of 1125 feet per second; in the present case, the waves are propagated in contrary direction, so that any given effect from the first wave is no longer continually accompanied by another given effect from the second wave. We must also recollect, that the motion of the particles in each wave of compression is in the direction of the propagation; so that a particle under the action of two waves of compression, has opposite velocities impressed upon it, and therefore moves with the difference of the velocities; and so on.

Now let A, B, C, D, &c., be the points where the two series of waves meet in the axis, and let us choose the instant of meeting for the time under consideration. Let the continued line represent the waves propagated from left to right, and the dotted line those propagated from right to left, as marked by the arrows at the parts at which they end; the arrows above them representing the directions of the absolute velocities which the waves over which they are placed give to the particles. (*Fig* 9). All the particles are now neither compressed nor rarefied; for it is evident that, whatever condensation or rarefaction a

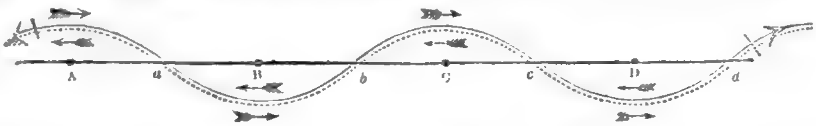
Fig. 9.



particle experiences from the wave moving to the right, there is a contrary rarefaction or condensation from that which moves to the left. But every particle has the velocity derived from either wave doubled by the other. Again, the particular points A, B, C, D, &c., are never put in motion; for it is plain that by the time any point P comes over C, giving it the velocity of P p to the left, the point Q, similarly placed on the other wave, will also have come over C, giving it the equal and contrary velocity Q q; so that, as far as velocity is concerned, all the impression produced on A, B, C, D, &c., is equivalent to two equal and contrary velocities, or to no velocity at all, for we are considering the case of particles, and not of rigid bodies, where such opposite equal forces would form a "*couple*," and produce *rotatory* motion. But when P has come over C, the compression, answering to P p, is doubled by that answering to Q q. So that the particles at A, B, C, &c., undergo no change of place, but only condensation or rarefaction. Also the particles at a, b, &c., halfway between A and B, B and C, &c., never undergo compression or rarefaction, but only change of velocity. For by the time any point R, from one wave, has come over a, with the condensation answering to R r, S will have come over it from the other, with the equal rarefaction answering to S s; so that the effect of the combined waves upon a, is always that answering to equal condensation and rarefaction, or no change at all. But the velocities answering to R r and S s are equal, and in the same direction; so that the points a, b, &c., have the velocities which one wave would have given them doubled by the other. Hence at a, b, c, &c., the particles suffer no change of state, but are only moved backwards and forwards. Now, let the time of half a wave elapse, in which case the types of the undulations will coincide, and those parts will be over the capitals on the axis, which are now over the small letters, and *vice versâ*, as in *fig.* 10, where the coincidence is denoted by a continued and dotted line together, the latter being, of course, a little displaced.

Half a wave since, all compression and rarefaction had disappeared throughout the tube, the velocity of every particle being double that which either wave would have caused. The case is now altered; no particle has any velocity, since there are the signs of equal and contrary velocities at every point of the tube; but every particle is either doubly compressed, or doubly rarefied, except a, b, &c., which, as we proved, are never either compressed or rarefied. In one more half wave, the phenomena of the first supposition will be repeated; that is, all condensation or rarefaction will be destroyed throughout, the particles however being all in motion, except A, B, &c., but in directions *contrary* to those they had at first; while, at the end of a fourth half wave, the phenomena of the second supposition will be repeated, that is, all velocity will be destroyed, the particles being all *condensed* or *rarefied*, according as they were before rarefied or condensed. The reader may easily convince himself of these facts by drawing the corresponding figures. To put the results before the eye, suppose the tube to be of a highly elastic material (thin India-rubber, for example), so as to bulge outwards a little when compressed from the interior, or to contract in diameter by the pressure of the outward air when the inward is rarefied. Recollect, also, that A, B, C, D, &c., remain without

Fig. 10.



motion, their only change being condensation or rarefaction; while a, b, c, &c., are never compressed or rarefied, their only change being that of place. We exhibit side by side the successive appearances of the tube, and the relative situations of the types between A and C, the arrows always representing the direction of the motion of the particles. A half-wave elapses between each two configurations. (*Fig.* 11.)

These phenomena will recur in the same order, and this mode of undulation, though it is necessary to show how it arises from the combination of two waves, is nevertheless more easy to be explained by itself than either of these two. For if we recollect that when particles of air move away on both sides from a given point, there must be a condensation in the parts towards which they move, and a rarefaction in those which they quit, (2) will evidently follow from (1). At this second period, the elasticity of the air will have opposed and destroyed the velocities of the particles; so that there now only remains a tube of particles at rest for the moment, condensed towards the ends and rarefied in the middle. There will therefore immediately commence a rush of air towards the rarefied parts, which will end by producing the

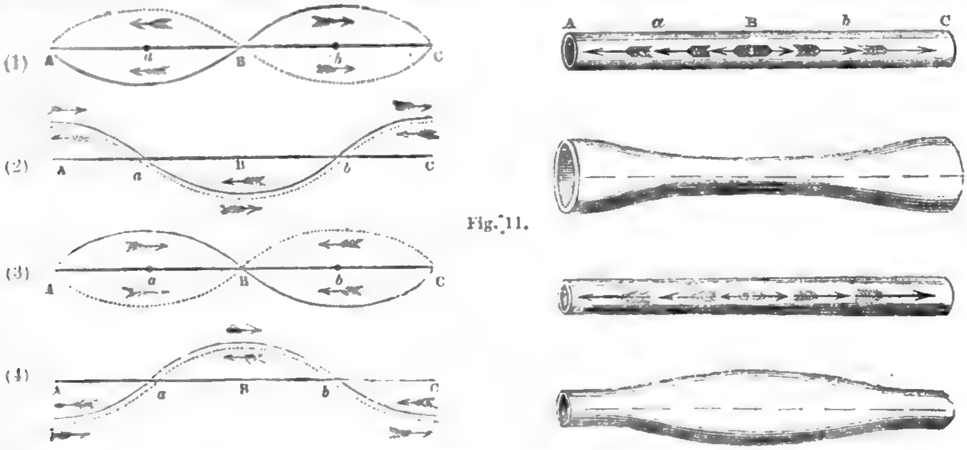


Fig. 11.

state represented in (3), where equilibrium is restored, as far as compression and rarefaction are concerned; but where, at the moment under consideration, nothing has yet taken place to deprive the particles of the velocity which they received from the elasticity of the air before the natural state was recovered. There is now a motion of particles, in all directions, towards B, which will go on producing compression at B, and rarefaction at A and C, until all the velocity is destroyed. This is the state represented in (4), from which (1) follows again; and so on. The states of the column intermediate between the times of (1), (2), &c., are easily imagined. Between (1) and (2) the compression at the extremities will have begun; but not yet to the complete destruction of the velocities. Between (2) and (3) the motion of the particles towards the middle will have begun; but will not yet have placed them in their natural positions; and so on. The particle at B, is evidently never in motion, being always equally pressed on both sides. The same would be seen of A, and C, if the tube were extended on both sides.

It is evident also, that except at the instant when compression and rarefaction are all destroyed, there must be a point at which the transition occurs from condensation to rarefaction; and *vice versâ*. It is not however so evident, in this way of viewing the subject, that these points always remain in the same position at a and b, which is the result of our previous investigation. The reader must however recollect, that, when we talk of the points a and b being always free from condensation or rarefaction, we do not say that it is *the same air* which is always uncondensed or unrarefied, but only that the different portions of air, which pass by a and b, are in their natural state at the instant of the passage.

Now it must be evident, that if, in the motion of a fluid, there be certain particles which remain at rest, it is indifferent whether we suppose those particles to be fluid or solid; for all that we know of a solid, as distinguished from a fluid, is, that the particles of the latter yield *sensibly* to any applied force, while those of the former do not. Hence, when such impulses are communicated to a fluid, that some of its particles must remain at rest, the question never arises, so to speak, as to whether those particles would, or would not, move with the fluid, or resist, if the conditions of motion were so altered, that forces, which did not counterbalance, would be applied to those particles. Let us now suppose that a solid diaphragm is stretched across the tube at A; the motion will still continue exactly as before; and we may produce this species of complex undulation by a piston at one end only of the tube, provided the other end be closed. For, on this supposition, all the successive states into which the air at the end furthest from the piston is brought, cannot be communicated to the outside air, and must, therefore, be either retained, or returned back again through the column of air. The latter effect results; and the returning wave, which is of the same kind as the advancing wave, produces the phenomena just explained. If A and B were both closed during an undulation, no piston would be necessary, if it were not that there is no substance but what will vibrate in some small degree, and the vibrations communicated to the tube from the internal air gradually destroy the internal motion, by the communication of motion to the external air.

We have hitherto considered only the motion of air in a small tube, and have found that the velocity of the particles, as well as the condensation and rarefaction, may be propagated undiminished to any extent. The case is somewhat different when we consider undulations propagated in all directions at once. Imagine a small sphere, which is uniformly elastic in every part, and which, by some interior mechanism, is suddenly diminished in its dimensions, and afterwards as suddenly restored. A wave of rarefaction and condensation will be propagated in every direction; which wave, at any instant, will be contained between two spheres, concentric with the sphere already mentioned, the radii of which differ by the length of the double wave: at least, unless there be some reason in the state of the atmosphere, why the propagation should take place more quickly in one direction than another. We have no reason, at first sight, to suppose that the velocity of propagation would be exactly, or even nearly the same as if a portion of the air through which the waves pass had been contained in a tube, unconnected with the exterior air. But it is found, both by mathematical analysis and experiment, that the velocity of propagation remains unaltered in both cases; and also that the *absolute* velocities of the particles diminish. This last is a natural consequence of a very simple principle—namely, that when one body, or collection of bodies, strikes a larger body, or collection of bodies, in such a way that its whole motion is destroyed, the velocity of the larger body will not be so great as that of the communicating body, but less in the same proportion as its mass is greater. The law of this diminution should be, from theory, *inversely as the distance*; that is, by the time the wave has moved from 3 miles to 5 miles, the compressions and velocities should be as 5 to 3; but we have no direct means of submitting this to experiment, the absolute velocities being imperceptible.

We now proceed to the application of these principles. We know that when the air is violently or rapidly propelled in any direction, undulations such as we have described are produced, and that the impression called *sound* is produced also. When a gun is fired, the great elasticity of the gases which are disengaged by igniting the gunpowder, forces the air forwards out of the gun, which the instant afterwards is allowed to return. If feathers or dust be floating in the air, they have been observed to move forwards, and then back again, just as we have found the particles of air around them would do in the course of a double wave. The intensity or loudness of the sound seems to depend upon the greatest absolute velocity of the particles, and not at all upon the velocity of propagation, which is found to be the same for all sounds. Thus in a musical chord, spring or drum, the harder the metal or parchment is struck, the louder is the sound, but without any difference of tone, character, or velocity of propagation. There is no instrument of which the sound may not be made louder or weaker without any other change than giving greater velocity to the immediate cause of sound. We will not enter further into this part of the subject than to observe, that, generally speaking, we are not authorised to say that sound travels with equal loudness in all directions. It might do so in the case where it was communicated by the sudden contraction and expansion of an elastic sphere, as above supposed; but this is a supposition which we cannot put in practice. If a tuning fork be sounded and turned round in the hand while held up before the ear, very perceptible diminutions and augmentations of loudness will be perceived. This is however explained *otherwise* on the principle of *Interference*, by the fact that when the branches coincide, or are equidistant from the ear, the waves of sound combine their effects, while in all intermediate positions, as they reach the ear in different phases of vibration, they interfere, and produce partial silence.

The immediate communicator of sound is the tympanum or drum of the ear, an elastic membrane, which is set in vibration by the motion of the particles of air against it, and vibrates in the same time with them. From this membrane vibrations are communicated to the fluid filling the *labyrinth* of the ear, through the air in the tympanic cavity, and probably not, as was formerly supposed, through the delicate chain of bones connecting them. [Ear, in Nat. Hist. Div. of Eng. Cyc.] We might expect, that when the wave of sound is of considerable length, we should hear its different parts, that is, feel a difference between the beginning and end where the velocities and compressions are small, and the middle where they are greatest. This happens to a small extent in the difference, for example, between the 'roar' of a cannon and the 'report' of a musket. No explanation can convey a better idea of the difference than these two words. These simple uncontinuing sounds are the result of few waves, there being no cause for their continuance.

We have not space in this article for any discussion of the manner in which sounds are conveyed through other bodies besides air, for which see Vibration. Noises conveyed through solid bodies travel in general more quickly, and are heard better; the scratch of a pin may be distinctly perceived through a long spar of wood, though inaudible by the person who makes it. With regard to gases, both theory and experiment agree in enabling us to assert, that any two of the same pressure and temperature, (that is, where the barometer and the thermometer would present similar indications in each gas,) convey sound with velocities which are inversely as their densities. Thus, air being about fifteen times as heavy as hydrogen, the velocity of propagation in the latter is about fifteen times that in the former. Such a result cannot be directly submitted to experiment; but, as we shall see in the article Pipe, there are methods equally certain for ascertaining the truth.

The velocity of sound had been determined by experiment before the time of Newton, who gave the first mathematical solution of the question, with the following result; that if the atmosphere, instead of decreasing in density as we ascend it, were all to be reduced to the density at the earth's surface, but to be so diminished in height, that the pressure at the earth's surface should not be altered, the velocity of propagation would be that acquired by a heavy body falling unresisted from half the height of this *homogeneous atmosphere*. This reasoning, however, gave the velocity nearly *one-sixth* too small; and the cause of the difference was afterwards supplied by the sagacity of Laplace. This we shall try to explain. We know that air and all gases resist compression, and will expand themselves if the pressure of the superincumbent atmosphere be removed. This tendency is what we mean by the *elastic force* of the air or gas. If we take a column of air reaching from the earth's surface to the top of the atmosphere, the elastic force at any one stratum is equal to the weight of the superincumbent column, since it balances that weight. Moreover, it is observed, that, *at the same temperatures*, the elastic forces of two different strata are as their *densities*, that is, for air of half the density of common air, the elastic force is only half as great, and so on. It is also observed that any increase of temperature increases the elastic force if the density remain the same, and also that compression always increases the temperature; and *vice versâ*. If, therefore, a vessel of air were pressed into half its dimensions, it would double its elastic force from the condensation, which would also receive a further addition from the increase of temperature. Again, if the same were rarefied into double its first dimensions, the elastic force would be halved by the rarefaction, and receive a further decrease from the diminution of temperature. The increase or decrease arising from temperature would not last long, since the altered mass would communicate heat to the surrounding bodies in the first case, and receive it from them in the second; but in calculating such instantaneous effects as the propagation of sound, it is evident they ought not to be neglected. The supposition on which Newton went was, that the elastic forces of two strata of air are always in the same proportion as their densities, which is not true, unless the temperatures are the same. We may also here remark, that an alteration in the *barometer* only, produces no alteration in the velocity of air; for, if the barometer rise, though the pressure of the air is increased, yet the density is increased in the same proportion; that is, the force which is to set each mass in motion receives no greater increase in proportion than the mass which is to be moved. But a rise in the thermometer, accompanied by no change in the barometer, increases the velocity of sound, for there is an increase in the elastic force, without any increase in the density. A very good measure of this velocity made near Paris in 1822, under the directions of the Academy of Sciences, gave 1118 feet per second at the temperature of 61° of Fahrenheit. Earlier experiments had given 1130 feet, which, if the French measure is assumed as accurate, represents the velocity at a somewhat higher temperature. The number which we have adopted, viz., 1125 feet per second, at 62° of Fahrenheit, is shown by Sir John Herschel, in his masterly treatise on 'Sound' in the 'Encyclopædia Metropolitana,' to accord very nearly with the mean of the best experiments. The formula for calculating this velocity is *now* given as follows:—

$$V = 1090{\cdot}8 \left\{ (1 + 0{\cdot}003665 \times t)\left(1 + 0{\cdot}375\,\frac{\Upsilon}{\Pi}\right) \right\}^{\frac{1}{2}}.$$

where t is the centigrade temperature, Υ the density of vapour, and Π that of air, at the time. Every increase or decrease of temperature of 1° of Fahrenheit, causes a corresponding increase or decrease of $1\frac{1}{10}$ of a foot in the velocity of sound, which gives about 1090 for the velocity when the air is at the freezing point. We may add, that in the present state of our knowledge of the manner in which the temperature and elastic force of the atmosphere are connected, observation and theory give results which differ from one another by about a hundredth part of the whole.

When the exciting cause of sound is continued, as for example, when a board is scratched with a pin, we have a continued sound, caused by the succession of waves which the ear receives, which waves we have no reason to believe are all of the same length. But whenever the exciting cause is one, the vibrations of which can be shown to be performed in exactly the same time, so that the waves caused by them are all of the same length, we perceive a sound which gives pleasure to the ear, and has the name of *harmonious* or *musical*. This, however, only happens when the vibrations are at least thirty in a second, or the wave of a sound at most about 38 feet long. This fact is so well established, that we may consider it as certain that the pleasure arising from musical sounds is a consequence of the perfectly equal times of the vibrations which produce them, and of its result, the equal lengths of the sonorous waves propagated from them through the atmosphere. This will not appear so extraordinary, if we consider the very delicate nature of our organ of hearing. A person of tolerable ear can distinguish between two sounds, which only differ in that the one is a consequence of 400 vibrations in a second, and the other of 405. We must therefore grant to the ear a much higher power of perception as to sounds than the eye has to length or surface. Some increase of the perceptive power may arise from the very great number of vibrations, since a result in some degree corresponding is observed in vision. If we look at a large number of parallel lines ruled close together at equal distances, any little deviation from parallelism or equidistance is much more sensibly seen than when the number of lines is small. And even to the eye, any moderately rapid succession of objects of the same kind is much more pleasing when they follow at equal distances and periods of time.

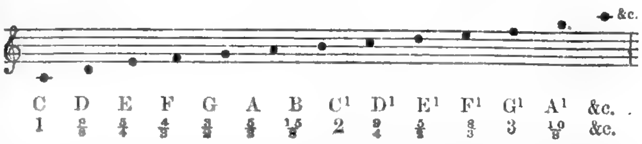
The difference between two musical sounds, which we express by saying that one is higher or lower than the other, is a consequence of the different number of vibrations performed by the two in the same time, and the sound which we call *higher* has the greater number of vibrations. And some sounds, when made together, produce an effect utterly unbearable, while others can be tolerated; others again are extremely pleasant, while some, though very different in pitch, appear so alike, that we call them the same, only higher. It is found by experiment that two sounds are more or less *consonant*, when heard together, according as the relation between their vibrations is more or less simple. Thus, when two vibrations of the first are made in one vibration of the second (which is the simplest ratio possible, when the sounds are really different), that similarity is observed to which we have just alluded; the first sound is called the *octave* of the second, and both are denoted in music by the same letter. When the number of vibrations of the two are as 3 to 2, the one which vibrates three times while the other vibrates two, is called a *fifth* above the other; because in the musical scale of notes

𝄞 C D E F G A B C' D' &c.

the vibrations of C and G are in this proportion, and G is the *fifth* sound reckoned from C. If the ratio of the vibrations be that of 3 to 4, that is, if the higher note makes four vibrations, while the lower note makes three, which is the case with C and its *fourth* F; or that of 4 to 5, which happens with C and its *third* E; the combined effect of the two is agreeable. The same may be said of C and its *sixth* A, in which the ratio is that of 3 to 5, or of E and its *minor sixth* [MUSIC] C^1, in which the ratio is that of 5 to 8; or of E and its *minor third* G, in which the ratio is that of 5 to 6. We write underneath (Fig. 12) the common musical scale in the treble clef, with the denominations of the notes and the fraction of a vibration which is completed while the first C completes one vibration, which fraction is greater than unity, as the notes are rising. Thus while C vibrates once, D vibrates once and one-eighth; or 8 vibrations of C take place during 9 of those of D.

This is the musical scale pointed out by nature, since all nations have adopted it, or part of it at least. It fully verifies our assertion that the ear delights in the simplest combinations of vibrations. It would be hardly possible to place between 1 and 2, six increasing fractions whose numerators and denominators should, on the whole, contain smaller numbers. We find, in the six intermediate fractions, only 2, 3, 4, and 5 singly, or multiplied by one another, no product exceeding 15. Neither has the whole of this scale always been adopted. It seems to have been formerly universal to reject F and B, the *fourth* and *seventh* of the scale; as is proved by the oldest national airs of the orientals, the northern nations, and even of the Italians [SCALE].

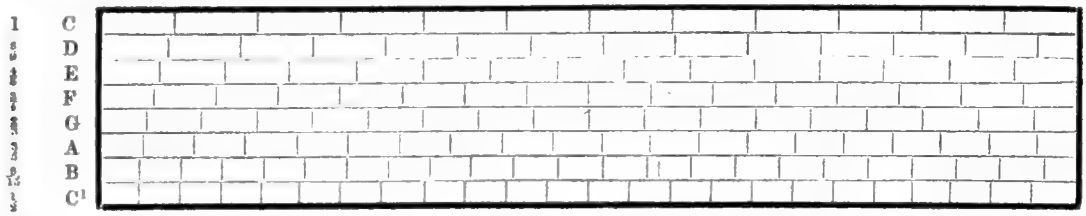
Fig. 12.



The following table will represent the proportions of the lengths of the sonorous waves which yield the preceding notes. These lengths decrease, as we have seen, as the *times* of vibration *decrease*, or as the numbers of vibrations in a given time increase.

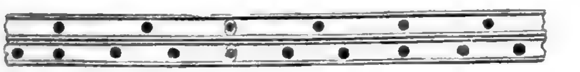
Now, let two of these notes be sounded together, for example, C and G, in which two waves of C are equivalent to three of G. The resulting wave is, as we have seen in the preceding part of this article, twice as long as the wave of C, and the curve which represents the condensation and velocity of the particles of air is compounded, as before described, of those of the waves of C and G. The ear is able to perceive three

Fig. 13.



distinct sounds, one of which is almost imperceptible, and indeed inaudible, unless carefully looked for. The two perceptible sounds are those of C and G from which the wave was made; nor are we well able to explain how this can be. Undoubtedly, if the curve, which is the type of the compound wave, were presented to a mathematician, he would be able, with consideration and measurement, to detect its elements; and to make that resolution which is done by the most unpractised ear. But we may, perhaps, assert that a savage, or a person totally unused to music, would not separate the sounds, but if C and G were sounded separately, and afterwards together, would imagine he had heard three distinct notes. The third sound, which is very faint indeed, is that belonging to the whole compound wave, which, being twice as long as the wave of C, belongs to the note called C, an octave below the first C of the preceding scale, which may be denoted by C^1. We may perhaps give an idea of this combination in the following way:—

Fig. 14.



Let us suppose a series of equidistant balls to roll past us at the rate of two in a second, and another series at the rate of three in a second,—and let us moreover suppose that these balls roll in tubes placed one over the other, so that we only see each as it passes an open orifice in its tube, as in Fig. 14. It is evident that we thus obtain three distinct successions: 1, that by which we might count 3 in a second from the lower tube; 2, that by which we might count 2 in a second from the upper tube; 3, that by which we might count single seconds, from observing when two balls pass together, and waiting till the same happens again. And we must recollect that any sound, however unmusical in itself, produces a musical note, if it be repeated regularly and often; so that it is not from the phenomenon itself, but from the frequency of its succession at equal intervals, that the pleasant sensation is derived. Thus in a passage, which has a strong echo, that is, where waves are reflected from wall to wall, as in the tube closed at both ends, already described, if the foot be struck against the ground, a faint musical note is heard immediately after the echo has ceased. By the action of the foot, shorter waves are excited, as well as the long wave, by the reflection of which the echo is caused. None of these would be repeated were it not for the reflection; but when the main sound is weakened by reflection, the shorter waves begin to produce the effect of a musical note, being, as we must suppose, less weakened than the longer wave. And we may here take occasion to observe, what will be further discussed in the articles PIPE and CHORD, that it is difficult to excite a perfectly simple wave, unaccompanied by shorter ones, which latter are always contained an exact number of times in the longer. Thus, if the note called C_1, or an octave below C in *fig.* 12, be struck on a piano-forte, the sounds G and E^1 (see the figure) will be distinctly heard as C becomes weaker, the waves of these notes being respectively one-third and one-fifth of those of C. When two notes are struck together, the effect is not pleasing, except when the numbers of waves per second in the two bear a very simple proportion.

We have noticed all the cases which the musicians call *concords*: the remainder, though contributing much to the effect of music, being called *discords*. Thus, if F and G be sounded together, in which (*fig.* 12) F makes $\frac{4}{3}$ of a vibration while G makes $\frac{3}{2}$, or F makes 8 vibrations while G makes 9, the effect is disagreeable, at least if continued for some time. On the piano-forte, in which the notes when struck subside into comparative weakness, this is not so much perceived; but on the organ, in which the notes are sustained, the effect is intolerable, and accompanied by an apparent shaking of the note, producing what are called *beats*, which we shall presently explain. Nevertheless, it becomes endurable, if not too long continued, provided F, the *discordant note*, as it is called, is allowed to pass to the nearest sound, which will make one of the more simple combinations of vibrations with G. The nearest such sound is E, which makes 5 vibrations, while G makes 6. For further information, we must here refer to the article HARMONY.

We now come to the absolute number of vibrations made by musical notes; all that we have said hitherto depending only upon the proportions which these numbers of vibrations have to one another; so that any sound might be called C, provided the sound produced by twice as many vibrations in a second were called C^1, and so on. From the measurements recorded in the 'Memoirs of the Academy of Berlin' for 1823, it appears that the middle A of the treble clef, or the A in *fig.* 12, was produced by the following numbers of waves per second in the following different orchestras, showing a *small* variation between them, but one by no means insensible to the ear:—

Theatre at Berlin	$437\frac{32}{100}$
Paris, French Opera	$431\frac{34}{100}$
— Comic Opera	$427\frac{61}{100}$
— Italian Opera	$424\frac{17}{100}$

From this we may form an idea how many vibrations are necessary to create the sensation of a musical sound, and also at what point of the scale the vibrations per second would become so numerous that this effect should cease. If we take one of Broadwood's largest pianofortes, and recollect that they are generally tuned (for private purposes) a little below the pitch of the orchestra, we shall not be far wrong in assuming that the A above-mentioned on these instruments is the effect of 420 vibrations per second. The lowest note, which is almost inappreciable (that is, though perfectly audible as a sound, yet hardly distinguishable from the notes nearest to it), is the fourth descending C from this A, and the highest is the third F above it, though the C above that, or the *fourth* ascending C from the A, can be well heard, and may be had by whistling into a very small key. We must, however, remark, that the point at which a series of undulations ceases to give a sound either from its slowness or rapidity, is different to different ears; sometimes so much so, that while one person complains of a note as too shrill, another cannot hear it at all. We write the above scale below, putting the A, whose vibrations we know, in its proper place,—

$$C_3 \quad C_2 \quad C_1 \quad C \quad A \quad C^1 \quad C^2 \quad C^3 \quad C^4.$$

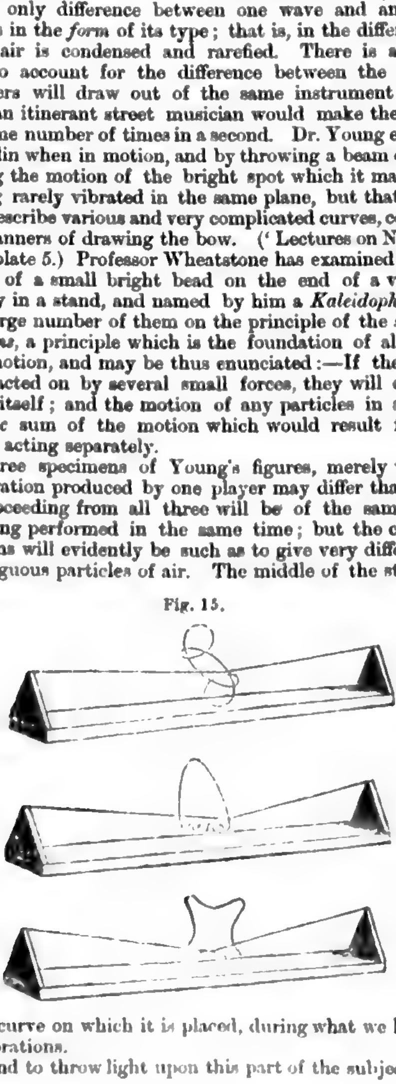
On looking at *fig.* 12, we see that A makes 5 vibrations, while C makes 3; that is, A making 420 vibrations per second, C makes 252; therefore, C_1 makes the half of this, or 126; C_2 makes 63, and C_3 $31\frac{1}{2}$. Again, C^1 makes twice as many vibrations per second as C, or 504; C^2 makes 1008, C^3 2016, and C^4 4032 vibrations per second. That is to say, in round numbers, the ear receives a musical impression from any sound which arises from a number of vibrations between 30 and 2000; and we may certainly say that, in every orchestra, the hearers are employed in distinguishing and discriminating between various rates of succession in the undulations of the air around them from 60 to 2000 per second.

We have previously alluded to a phenomenon of sound, or rather of combined sounds, called a *beat*. If two notes whose vibrations are either nearly in the same ratio, or nearly in one of the simple ratios above-mentioned, be sounded together, the effect of their being out of tune is a tremulous motion of the sound, the pulsations or beats of which can be counted if the notes be not too high. For example, suppose two simultaneous notes whose vibrations are 100 and 104 per second. Here 25 vibrations of the first are made during 26 of the second; and the reader who has studied the preceding part of this article will see that the resulting wave is as long as twenty-six of the second waves; but that if the waves from the two be much alike in their types, this resulting wave will consist of a cycle of rarefactions and condensations very much resembling the separate waves. The whole resulting wave being twenty-six times as long as the second wave, will run through all its changes *four* times in a second, which is not sufficient to give a musical sound, but will only add to the sound of one of the waves the periodical tremulous sensation which is called a beat, which may be imitated by ringing the syllables *who, ah*, in rapid succession on the same note of the voice. If, however, these *beats* recur at sufficiently short intervals to produce on the ear the impression of a continuous sound, a new note, called the *grave harmonic*, is heard, lower than either separately. For information as to the use made of these beats, see the article TEMPERAMENT.

It only remains to consider the different character of sounds. The same note, as to *pitch* or tone, may be sounded by a horn and a flute; nevertheless, each instrument has a character of its own, which enables every one to distinguish between the two. It is not to the different loudness of the two, for either, by skilful players, may be made to give the weaker sound; neither does it depend on the number of vibrations, for that, as we have seen, determines only the pitch of the note: the only difference between one wave and another of the same length, is in the *form* of its type; that is, in the different manner in which the air is condensed and rarefied. There is also only this feature left, to account for the difference between the tones which different players will draw out of the same instrument; since both Paganini and an itinerant street musician would make the same string vibrate the same number of times in a second. Dr. Young examined the string of a violin when in motion, and by throwing a beam of light upon it and marking the motion of the bright spot which it made, he found that the string rarely vibrated in the same plane, but that the middle point would describe various and very complicated curves, corresponding to different manners of drawing the bow. ('Lectures on Natural Philosophy,' vol. ii. plate 5.) Professor Wheatstone has examined these curves by the motion of a small bright bead on the end of a vibrating rod, fixed vertically in a stand, and named by him a *Kaleidophone*, and has calculated a large number of them on the principle of the *super-position of small motions*, a principle which is the foundation of all the science of vibratory motion, and may be thus enunciated:—If the particles of any body are acted on by several small forces, they will obey each, as if it acted by itself; and the motion of any particles in any direction is the *algebraic* sum of the motion which would result from the disturbing forces acting separately.

We give three specimens of Young's figures, merely to show how much the vibration produced by one player may differ that of another. The waves proceeding from all three will be of the same length, the vibrations being performed in the same time; but the condensations and rarefactions will evidently be such as to give very different relative states to contiguous particles of air. The middle of the stretched wire

Fig. 15.



describes the curve on which it is placed, during what we have hitherto called two vibrations.

It might tend to throw light upon this part of the subject if practical musicians would observe, in the same manner, the curves which they produce, and describe the different qualities of tone arising from them. As yet, we have no direct experiments which tend to connect any particular form of vibration with any particular quality of sound. We shall enter upon the best method of doing this in the article CHORD.

Some confusion arises in books on this subject, from the use which different authors make of the words *vibration* and *wave*. Some mean, by a vibration, a motion to and fro, while others call the same motion *two* vibrations; and by a wave, the complete succession of condensations and rarefactions, which others call *two* waves, one of condensation, the other of rarefaction. For further information, we refer the reader to Sir J. Herschel's article, already cited, to Robison's 'Mechanical Philosophy,' Biot's 'Précis Elémentaire de Physique,' and Pouillet's 'Traité de Physique.'

ACQUITTAL from the French *acquitter*, to free or discharge, signifies a deliverance or setting free of a person from a charge of guilt. One who, upon his trial for a criminal offence, is discharged by the jury, is said to be acquitted. The acquittal by the jury has, however, no force in law until judgment has been given upon the verdict by the court. After this judgment, if the party be indicted a second time for the same offence, he may plead his former acquittal in bar, as a complete answer to the second charge, by what is called a plea of *autrefois acquit*. Upon this plea being admitted or proved, the person indicted will be entitled to be discharged, as the law will not permit a man to be twice put in danger of punishment for the same offence.

ACQUITTANCE is a discharge in writing of a debt, or sum of money due. A general receipt or acquittance in full of all demands will discharge all debts, except such as are secured by what are termed specialties, viz. bonds and instruments under seal, which are considered by the law as of too great force to be discharged by a verbal concord and agreement, or any less formal and solemn acquittance than a deed. Where an acknowledgment of satisfaction is by deed, it may operate as a good answer to an action on the debt, even though nothing has ever been actually received.

Courts of equity, and even courts of law in some cases, will order accounts to be gone into anew, notwithstanding the production of a general acquittance or receipt in full of all demands, upon proof that such acquittance was obtained by fraud or given under a mistake, and that the debt or other demand has not been in fact satisfied.

ACRE, a measure of land, of different value in the different parts of the United Kingdom. When mentioned generally, the statute or English acre is to be understood. Its magnitude may be best referred to that of the square yard by recollecting that a square whose side is 22 yards long is the *tenth* part of an acre; whence the latter contains $22 \times 22 \times 10$, or 4840 square yards. The chain with which land is measured is 22 yards long; so that *ten* square chains are one acre. This measure is divided into 4 roods, each rood into 40 perches, so that each perch contains $30\frac{1}{4}$ square yards. Thus:—

Acre.		Rood.		Perch.		Square yards.	Side of equivalent squares in yards.
1	=	4	=	160	=	4840	69·5701
		1	=	40	=	1210	34·7851
				1	=	$30\frac{1}{4}$	5·5

The Irish acre is larger than the English, inasmuch as 100 Irish acres are very nearly equivalent to 162 English acres. More correctly, 121 Irish acres are 196 English acres; but the former ratio points out an easier arithmetical operation, and will not be wrong by so much as one acre out of 5000.

The Scottish acre is also larger than the English, 48 Scottish acres being equal to 61 English acres. There are also local acres in various parts of England, such as the Cheshire acre of 8 yards to the pole. The English statute acre is used in the United States of North America.

The French *Are* is a square whose side is 10 metres, and 1000 English acres are equivalent to 40,466 ares.

ACROLEINE ($C_6H_4O_2$), a substance obtained by the dehydration of glycerine ($C_6H_8O_6 = C_6H_4O_2 + 4HO$), and by the oxidation of allylic alcohol ($C_6H_6O_2 + O_2 = C_6H_4O_2 + 2HO$). It was obtained by Redtenbacher by the distillation of glycerine with phosphoric acid. The operation must be carried on in vessels charged with carbonic acid gas, as acroleine is rapidly oxidised in atmospheric air. It may be regarded as the hydride of a radical called *acryl*. This substance resembles acetyl, or othyl, and represents in acroleine the position of acetyl in acetic aldehyde. Thus, $H, C_6H_3O_2$ is the atomic constitution of acroleine, which when oxidised in the atmosphere becomes converted into *Acrylic acid*, $HO, C_6H_3O_3$, a substance perfectly analogous to acetic acid. Acroleine is often formed as a result of the distillation of oils and fats. Thus, castor-oil yields acroleine and some other peculiar products on distillation.

Acroleine is a limpid colourless liquid. Its vapours are intolerably pungent and suffocating (whence its name), attacking the eyes and respiratory organs most violently; a very minute quantity will produce this effect. The unpleasant, pungent smell of a blown-out candle when the wick is left in a state of ignition is due to a trace of this substance. Its sp. g. is less than that of water; it boils at 125°, and is soluble in 40 parts of water. Even in sealed vessels it cannot be long preserved, becoming converted either into a white, flocculent, inodorous powder called *diracryle*, which is insoluble in water, alkalies, acids, oils, and bisulphide of carbon; or into a resinous substance called *resin of diracryle*, which is soluble in alkalies, alcohol, or ether, but insoluble in water. Diracryle is probably isomeric with acroleine.

ACRO'NYCHAL (sometimes incorrectly written Acronical, and Achronical), a word derived from the Greek, signifying 'that which determines the extremities, or the beginning and end, of the night.' It is only used in reference to the rising or setting of the stars; and a star is acronychal or rises acronyeally when it rises at or very near sunset, and consequently sets at or near sunrise. To determine what stars rise acronychally on any given night, elevate the pole of a common globe so that the arc intercepted between it and the horizon may be equal to the latitude of the place. Turn the globe until the sun's place is on the horizon at the *western* side, then will all stars which are either on or within a short distance of the horizon on the *eastern* side be acronychal.

ACROSTIC, a Greek term, signifying literally the beginning of a line of verse. An acrostic is a number of verses so contrived that the first letters of each being read in the order in which they stand shall form some name or other word. According to some authorities, a writer named Porphyrius Optatianus, who flourished in the 4th century, has the credit of being the inventor of the acrostic. It is probably, however, of older date. Eusebius, the bishop of Cæsarea, who died in A.D. 340, gives in his 'Life of Constantine,' a copy of Greek verses which he asserts to be the composition of the Erythræan Sibyl, the initial letters of which make up the words ΙΗΣΟΥΣ ΧΡΙΣΤΟΣ ΘΕΟΥ ΥΙΟΣ ΣΩΤΗΡ, that is, 'Jesus Christ, the Son of God, the Saviour.' These verses, which are a description of the coming of the day of judgment, have also been translated into Latin hexameters, so as to preserve the acrostic in that language, in the words JESUS CHRISTUS DEI FILIUS SERVATOR. The translation, however, wants one of the wonderful qualities of the original; for it will be observed that the initial letters of the five Greek words being joined together, form the word ΙΧΘΥΣ, that is, 'the fish,' which St. Augustine, who quotes the verses in his work entitled 'De Civitate Dei,' informs us is to be understood as a mystical epithet of our Saviour, who lived in this abyss of mortality without contracting sin, in like manner as a fish exists in the midst of the sea without acquiring any flavour of salt from the salt water. This may be therefore called an acrostic within an acrostic. But there are also other ways of complicating these ingenious productions. Addison, who notices this along with other sorts of false wit, in his lively papers on that subject, in the first volume of the 'Spectator,' says, "there are compound acrostics, where the principal letters stand two or three deep. I have seen some of them where the verses have not only been edged by a name at each extremity, but have had the same name running down like a seam through the middle of the poem." There are even instances of the same name being five times repeated in so many successive columns. Such an acrostic has been designated a pentacrostic. This species of elaborate trifling was extremely fashionable among the early French poets, from the age of Francis I. down to that of Louis XIV. Some also of our English poets of considerable eminence used formerly to amuse themselves in the same way. Thus, for instance, among the works of Sir John Davies, are twenty-six short poems, entitled 'Hymns to Astræa,' each of which is an acrostic on the words Elizabetha Regina. These, which were first published about the end of the 16th century, are perhaps the most elegant compositions of this description in any language. Afterwards such puerile ingenuity fell into disrepute; and Dryden, in his 'Mac-Flecknoe' (published 1682), thus contemptuously makes the dying monarch of the realms of nonsense and dulness address his son and successor Shadwell:—

> "Leave writing plays, and choose for thy command
> Some peaceful province in acrostic land."

The acrostic, being addressed merely to the eye, and conveying no pleasure either to the imagination or to the ear, cannot of course add to the poetical effect of the lines which it ornaments—any more than would the printing of the initial letters in a differently coloured ink. But it is sometimes useful, as an aid to the memory, in recollecting such verses as are composed only to be got by heart, for the sake of the facts of which they form a summary. Thus, in some editions of the Latin dramatist Plautus, we find prefixed to each play a few verses which contain at the same time an acrostic on its name and a sketch of the plot. In this case, the knowledge of the initial letter of each line must help the memory to recover it, if it should be forgotten. There are two epigrams in the Greek Anthology, one in honour of Bacchus and the other of Apollo, which are called acrostics, though of a somewhat peculiar fashion. Each contains twenty-five verses, of which the first introduces the subject of the poem, and each of the twenty-four others consists of four words, which are epithets of the god: all the epithets in the first line begin with A, those in the second with B, and so on. These poems, therefore, are merely acrostics on the alphabet, four deep. The Jews sometimes employ a sort of acrostic in designating many of their writers. Thus the commentator on 'Maimonides,' Rabbi Yom Tof bar Abraham, is commonly called Ritba, from the initial letters of the five words composing his full title. (In the article entitled 'Literary Chronology,' in the 'Companion to the Almanac for 1832, many illustrations of this practice are given.') The initial syllables of the verses of the Psalms were anciently called acrostics. The following is a curious specimen of a Latin acrostic:—

S A T O R
A R E P O
T E N E T
O P E R A
R O T A S

ACROTE'RION (in Architecture), from the Greek Ακρωτηριον, 'the extremity of anything.' It is used technically to designate the pedestal which supports the statue or other ornament on the summit or upper angle, and is sometimes applied also to the similar ornaments over the feet, or lower angles, of a pediment; in the latter case they are all included under the plural *acroteria*. Some writers understand by this term also the statues which are placed upon the pedestals, but this use of the term is unsanctioned by any ancient authority. It may, however, with propriety be used much more extensively than has been the custom. The *finial* on the apex of a spire, pinnacle, or gable, in works of pointed architecture, is an acroterion; and in St. Paul's Cathedral in London, although the pediments over the entrance fronts have their acroteria, yet the acroterion of the edifice is the cross which surmounts the grand central part of the composition. This term is not found in many ancient authors; we derive it from Vitruvius, who uses it in the plural sense above-mentioned.

ACRYL. [ACROLEINE.]

ACRYLIC ACID. [ACROLEINE.]

ACT OF FAITH. [AUTO DA FÉ.]

ACT OF PARLIAMENT. [STATUTE.]

ACT. This word is a form of the Latin *actum*, from the verb *agere*, which is used generally to express the doing of any act whatever. *Actum verbum generale est sive verbis sive re quid agatur* (D. 50, 16, 19). The Latin word Actio, from which our word action is derived, had, among other significations, various legal meanings. Of these meanings one of the most common was the proceeding by which a man pursued a claim in a court of justice, who was accordingly in such case called the Actor. (D. 40, 12, 7 sub fin., and 'Cicero in Partit.' c. 32.) In this sense we have in our language the expression Action at Law. The word Act, a thing done, is sometimes used to express an act or proceeding of a public nature, of which sense the most signal instance among us is the term Act of Parliament, which means an act in which the three component parts of the sovereign power in this country, King, Lords, and Commons, unite; in other words, a Law properly so called. In this sense also, as expressing a proceeding of a public nature, it is used in our English Universities to signify the exercise by which a candidate for the higher degrees in Divinity, Law, and Medicine shows his proficiency. In scholastic phrase, "to keep an act" meant to perform publicly an exercise in Latin, accompanied with a Latin thesis. The word Act is also sometimes applied to denote the record of the Act, and by the expression Act of Parliament is now generally understood the record of an Act of the Parliament, or the written record of a Law. In the French language, also, the word *acte* denotes a written record of a legal act, the original document, which is either private, *acte sous seing privé*, which requires the acknowledgment of the parties in order to complete evidence (for the regulations affecting which, see 'Code Civil.' art. 1322, *et seq.*), or a public authenticated act, *acte authentique*, which, without such acknowledgment, is considered genuine and true, the probatio probata of that which it contains. ('Code Civil.' art. 1317.) This meaning of the word Act or Acts is derived from the Romans, among whom Acta signified the records of proceedings, and especially public registers and protocols in which the acts and decrees of the public bodies and functionaries were entered, as Acta Populi, Principum, Senatûs, Magistratuum. (Sueton. 'Julius Cæs.' c. 20.) The 'Acta Publica,' or 'Diurna' or 'Acta Urbis,' was a kind of Roman newspaper, or a species of public journal for all Rome (Cic. Attic. 6. 2. 6; Tacitus, 'Ann.' 13 c. 21), as opposed to the private journal (diurna) which, according to the old Roman love of order, each family had to keep. Augustus had one kept in his house, in which were entered the employments and occupations of the younger members of his family. Julius Cæsar established the practice of drawing up and publishing the Acta both of the senate and the people. (Suetonius, 'Julius Cæsar,' 20.) Augustus subsequently forbade the publication but not the drawing up of the Acta, and the practice of keeping such records continued, in some shape or other, even to the time of the Emperor Julian. Only a few fragments of them are extant. They are not unfrequently referred to as authorities by the Roman writers. (Sueton. 'Claudius,' c. 41.) These Acta were journals of the proceedings of the bodies to which they belonged, and of the chief events that took place in Rome. When Suetonius says ('Augustus,' 36) that Augustus forbade the publication of the Acta of the Senate, it must not be supposed, with some critics, that the Senatus Consulta are included in the Acta, for the business of writing and recording the former was a far more solemn and important one, as may be seen in Livy (iii. 517) and Suetonius ('Julius Cæsar,' 28, and 'Augustus,' 94.)

Under the Germanic Empire the term Acta Publica denoted the official transactions of the empire, decrees and the reports of the same, which were first collected under this title by Caspar Loedorpius (Frankfort, 1629), and his continuators.

The word Acta has been used in an analogous way in other instances in modern times. The 'Acta Sanctorum' denote generally all the old stories of the martyrs of the Church; and, specially, that large work begun in 1643 by the Jesuit Bolland, and continued by his successors to 1794, in 53 folio volumes, which contain such accounts. The 'Acta Eruditorum Lipsiensia' was the title of the first learned and critical review that was published in Germany, after the model of the French 'Journal des Savans,' and the Roman 'Giornale de' Litterati.' It was established in 1680, by Otto Mencken, a professor of Leipzig, and written in Latin. It was published monthly, and was continued for a century. Other journals of a like kind also adopted the name of Acta. The name of 'Transactions' is now given in England to the Acts of most learned and scientific bodies: the Acts of the Courts of Justice, so far as they are made public, are called 'Reports,' the 'Acta forensia' of the Romans, D. 26. 8. 21, while the proceedings of the courts as registered are called 'Records.'

(Rotteck and Welcker, *Staats-Lexicon*, art. by W.)

ACT (in the Drama), that portion of a play which is separated from the rest by an interval, during which the stage is left empty, and the action is supposed to proceed unseen by the spectators. In the Greek drama there were no acts; although in some modern editions, such as Burton's 'Pentalogia,' we find Greek plays thus divided. The language does not possess a word answering to the Latin and English 'Act.' Among the Greeks the stage was never left empty from the beginning to the end of the performance. When the other actors retired, those forming the chorus still remained, and continued the business of the play by their songs. For these songs, it is important to observe, were in general essential parts of the drama; they were not of the nature of a piece of music, or a dance, or any other extrinsic representation, thrown in merely to fill up a chasm in the action; they carried forward the action in the same manner as the ordinary dialogue did. For an exact copy of the form of a Greek drama in this respect, the English reader may be referred to the 'Sampson Agonistes' of Milton. In that play there is no division into acts; nor is there any such division in Buchanan's two Latin tragedies, entitled, 'Jephthes' and 'Baptistes,' which are also professedly composed upon the Greek model. The latter poet, we may add, has followed the same plan in his translations of the 'Medea' and the 'Alcestis' of Euripides. From this constitution of the Greek drama, it naturally followed, that the real duration of the action of any play could not well be supposed greatly to exceed that of its theatrical representation. In other words, what has been called the Unity of Time became a principle almost invariably observed in every dramatic composition. On the Roman stage there was no chorus, and the play was divided into acts, as on our own. But, although Plautus has frequently in his comedies supposed a considerable portion of time to pass between the close of one act and the opening of another, the most famous of the Latin dramatists, Terence, has not availed himself of this liberty, but has adhered closely to the practice of his Grecian models, in not permitting the interval between the acts to form more than a very short interruption of the progress of the story. By modern dramatists, however, the practice of dividing a play into acts has generally been taken advantatage of to extend the time of the story greatly beyond the space to which it was necessary to confine it on the Greek stage. Each act, in fact, is now what the Greeks would have called a separate drama, except that it does not contain a complete plot; and the whole play may be compared to those Trilogies of the Greeks, in which three dramas, representing so many successive separate parts of the same history, followed one another in one theatrical exhibition. Perhaps it was this consideration which made the Romans call each of the separate portions in question an Act or *Actus;* for that word is exactly a translation of the Greek δραμα, which was used to designate an entire play. The term, therefore, may be taken as, in its original and proper sense, denoting a distinct and, to a certain extent, independent theatrical action or picture, although capable also of being introduced as one of a series of such pictures, united by some common subject. And this is precisely what Shakspere must be understood to mean, when, in the famous speech which he puts into the mouth of Jaques, in 'As you like it,' comparing the world to a stage, he goes on to say, "One man in his time plays many parts, his *acts* being seven ages." The infant, the school-boy, &c., are acts only in the sense of being so many separate pictures or exhibitions of human life, each complete in itself, although following each other according to a natural order of succession, like the acts of a play. Viewed in this light, it will be perceived that the division into acts is really that distinction of the modern drama which, more than anything else, gives to it its peculiar character. Dr. Johnson has observed that, in modern plays, "The time required by the fable elapses, for the most part, between the acts; for of so much of the action as is represented, the real and poetical duration is the same. . . . . . The drama exhibits successive imitations of successive actions; and why may not the second imitation represent an action that happened years after the first, if it be so connected with it, that nothing but time can be supposed to intervene. Time is, of all modes of existence, most obsequious to the imagination; a lapse of years is as easily conceived as a lapse of hours." In the rude exhibitions of the English stage before Shakspere, the violation of the classical unities was startling to educated minds. Thus Sidney, in his 'Defence of Poesy,'—"Where the stage should always represent but one place, and the uttermost time presupposed in it should be, both by Aristotle's precept and common reason, but one day, there is both many days and many places inartificially imagined."

We may here remark, that although the French dramatic writers have adhered to the principle of leaving the stage empty only at the end of an act, many of the English have followed a different practice. In Shakspere particularly, every successive scene uniformly presents a new set of characters, and most commonly a change of place also. He rarely interrupts the action, however, for any considerable space, except during the interval between two acts; but here he does not hesitate to pass over any length of time he may find convenient. In the 'Winter's Tale,' Perdita, who was a new-born infant at the end of the third act, is grown up a young woman at the beginning of the fourth. In this instance, indeed, the dramatist introduces Time to explain and apologise for the license he had taken to

> ——————"Slide
> O'er sixteen years, and leave the growth untried
> Of that wide gap."

Time is here said to appear 'as Chorus;' and in the beginning of Henry V., Chorus is also brought forward to request the audience to allow their thoughts in the course of the representation to pass from one place to another;

> ——————"Jumping o'er times;
> Turning the accomplishment of many years
> Into an hour-glass."

Neither of these personages, however, performs exactly the office of the ancient Chorus.

We may add, that the old English Mysteries and Moralities, the first produce of our national dramatic genius, were long destitute of any division either into scenes or acts. The earliest of the Moralities which assume the regular dramatic shape, are not more ancient than the beginning of the reign of Elizabeth. Moralities continued to be both printed and acted long after this date. 'The Chester Mysteries' were performed in the year 1574. Down to this time there is every reason to believe that the scene never was changed from the beginning to the end of any stage-spectacle.

As for the Moralities, they were acted even in the reign of James I., and they are enumerated under the name of 'Morals' in the license granted to the company of which Shakspere was a member in 1603. But even several of our early tragedies and comedies, down to an era subsequent to this, were without any division into either scenes or acts. There is no such division in Preston's 'Cambises,' the play to which Shakspere is supposed to allude in 'Henry V.,' and which the author entitles 'A lamentable Tragedy mixed full of pleasant Mirth,' printed in 1561; nor in Peele's 'David and Bethsabe,' which appeared in 1579. In the tragedy of 'Soliman and Perseda,' 1599 (supposed to be by Kyd), there are acts, but not scenes; but there are neither one nor other in Dekker's 'Satiromastix, or the Trussing of the Humorous Poet,' nor in the comedy of the 'Wily Beguiled,' both of which appeared after the commencement of the 17th century, the latter so late as 1623.

Much discussion has taken place among the critics, on the reasons of the rule which restricts a regular dramatic composition to the extent of neither more nor less than five acts; and which Horace, in his 'Art of Poetry,' has laid down in a peremptory and well-known verse. Upon this subject the French writer, Marmontel, has delivered a very sensible judgment, the substance of which is, that the rule neither stands upon such a foundation as to constitute it an essential law, nor is it so unreasonable as to deserve to be banished from the theatre. The action must have its just extent given to it, and no more. The law of nature must be followed, which is superior to that of art.

ACT, in the universities, an exercise to be performed by students before they are admitted to their degrees. In the University of Oxford it has almost fallen into disuse, and in Dublin is a mere form; but at Cambridge it is still preserved as a preliminary test of the comparative merits of the candidates for the degree of Bachelor of Arts, who aspire to University honours. It is also performed by candidates for the degrees in law, physic, or divinity. The student proposes certain questions connected with his subject to the presiding officer of the *schools* (the place in which acts are kept), who thereupon nominates other students to oppose them. The discussion is carried on syllogistically and in Latin, and terminates by the presiding officer questioning the *respondent* or the person who is said to "keep the act," and his *opponents*, and dismissing them with a short compliment to each, in proportion to his deserts.

ACTA DIURNA (proceedings of the day) was the title of a gazette, to use the nearest modern term, drawn up and published daily at Rome, both under the republic and the empire. It appears to have contained an abstract of the proceedings of the public assemblies, of the law courts, of the punishment of offenders, an account of any public buildings or other works in progress, together with a list of births, deaths, marriages, and divorces, &c. In the very earliest times of Rome, provision was made under a religious sanction for the due registration of birth, assumption of the *toga virilis* (or dress of manhood), and death, accompanied by the payment of a certain fee into the respective treasuries of the goddesses Juno, Lucina, Juventas, and Venus Libitina. From the registers thus formed such extracts as were important might be made for publication. The law courts would furnish authority for the statement of divorces; and in this article of news there was no deficiency. Not a gazette appears, says Seneca, without its divorce, so that our matrons, from constantly hearing of them, soon learn to follow the example. The due supply of information on political and judicial affairs was to be obtained, as now, by reporters (*actuarii*). In the celebrated debate of the Roman Senate, upon the punishment of those who had been concerned in the Catilinarian Conspiracy, we find the first mention of short-hand writers, who were specially employed by Cicero to take down the speech of his friend Cato; and it is interesting to observe that this was the only speech of that extraordinary man which still existed in the age of Plutarch. But it must not be inferred, from this fact, that these reporters or any other persons were at liberty to publish an account of any proceedings in the senate. Until the first consulship of Julius Cæsar the senate was a close court. This great man, by a ludicrously distorted view of Roman history, has been generally represented as the destroyer of his country's liberties; yet he no sooner entered upon his office than he made provision for giving the same publicity to all the proceedings of the senate which already existed for the more popular assemblies; and this single act was perhaps the most fatal blow which Cæsar gave to the aristocratic interest. (Suetonius, 'Life of Julius Cæsar,' c. 20.) Under the despotism of Augustus such an institution was inconvenient, and therefore repealed. The *Acta* of the senate, though, of course, still registered, were no longer published; and, as all the popular assemblies were now deprived of real authority, the 'Acta Diurna' henceforward can have had little political interest. What disgraceful news they sometimes recorded, Suetonius tells us, in his 'Life of Caligula,' c. 36. Even in its best days this state-gazette was no doubt, an extremely meagre document,—conducted as it was on government authority, without the advantages of competition, and what is still more important, without the possibility of extensive circulation; for what could a newspaper have been before the art of printing was discovered? Yet, with all these disadvantages, the 'Acta Diurna' were often consulted and appealed to by the historians of after times, as documents of the highest authority, whilst in the Imperial times they were placed on an equality with the Fasti. "Sic enim in fastos Actaque publica relatum est," says Suetonius (Nero, 5). (For a more minute account, see Lipsius in his *Excursus on the Annals of Tacitus.* Lib. v. c. 4.)

ACTINO'METER (from ακτὶν, a sunbeam; and μετρον, a measure) is an instrument employed for the purpose of ascertaining the intensity of the heat of the direct rays of the sun. It consists of a hollow cylinder of glass, united at one end to a thermometer-tube, the latter being terminated at the upper extremity by a ball which is drawn to a point and broken off so as to leave a very small orifice, which is closed with wax: to this tube is applied a scale of equal parts. The other end of the cylinder is closed by a metal cap furnished with a silver screw, which turns tightly in a collar of leathers; the cylinder is filled with ammonia-sulphate of copper (a deep blue fluid), and the actual temperature of this fluid (on which its dilatability depends) is ascertained by an interior thermometer. The cylindrical portion, which acts as a bulb to the graduated stem, is inclosed in a box which is blackened within on three sides. The box has a thick glass in front, and the use of the screw is to diminish or increase the capacity of the cylinder. The instrument was invented by Sir John Herschel, who described it in the 'Edinburgh Journal of Science' for 1825. His objection to the indications of the thermometer as a means for indicating the heating power of the solar rays, is, that the various radiating effects of surrounding objects greatly interfere with the success of such observations, and that *time* ought to be considered as an element in the observations.

In making the observations with the actinometer, the instrument is disposed so that the sun may shine on its glass face, when the liquid will mount rapidly in the thermometer-tube. At the end of three or four minutes the extremity of the liquid is brought to the zero of the scale by turning the screw; after which, at the end of one minute, two minutes, and three minutes respectively, the observer registers the number of the graduation corresponding to the top of the column of fluid as it continues to rise. The instrument being then covered with a screen, three observations are made as before, at intervals of one minute, as the liquid descends in the tube. The instrument is again placed so that the sun may shine upon it, and afterwards in the shade, when two other sets of observations are made, and so on.

A mean of the two differences between the readings at two nearest observations while the sun was shining on the instrument, added to the difference between the readings at the intermediate observations while the instrument was in the shade, is taken as a measure of the intensity of the sun's radiation at the middle time between the first and third observations; and a mean of such results for all the triplets of observations is considered as the general mean.

The length of a degree on the thermometric scale is at present arbitrary, and the relative values of the degrees on the scales of different instruments are determined by comparing together the indications made in like circumstances. Sir J. Herschel proposed to establish, as a unit for the intensity of solar heat, that value which would, in one minute of time, dissolve a thickness equal to one millionth part of a mètre of a horizontal sheet of ice when the sun's light falls vertically upon it. This he calls an *actine;* and, from experiments made by him at the Cape of Good Hope, he determined the value of a degree on the scale of one of his actinometers to be equivalent to 6·093 actines.

The actinometer is useful in determining the quantity of solar heat which is absorbed in passing through different strata of the atmosphere, for which purpose the observations must be made at stations differently elevated above the general level of the earth or sea. It may also be employed to determine the diminution of heat which takes place during eclipses of the sun.

The reader interested in the subject, will find full details respecting this instrument in the 'Manual of Scientific Enquiry," published by the Board of Admiralty.

ACTION is a Roman term (*actio*), and signifies the legal process by which a man claims possession of some specific thing to which he has a right, or requires another to do something which he has agreed to do, or to make pecuniary compensation for neglecting to do it; or by which he claims pecuniary satisfaction for the illegal act of another to his person or property. It is necessary here to notice briefly that celebrated division of Roman Actions, viz., those *in rem* (*vindicationes*), and those *in personam*, generally termed *condictiones*, though this word is strictly applicable to such actions as arose from unilateral transactions, and were brought for the recovery of property.

The Roman *Actio in Rem* was the action in which a man claimed a thing from another as his property, or some use of a thing; and the action might be against any person who disputed his right. To this class belonged all those actions which by their nature could, as a general rule, be instituted *by* a person merely by virtue of some right vested in him *against* any one who disputed or obstructed such right, and *for* the purpose of compelling him to respect it. On the other hand, the Roman *Actio in Personam* was against some determinate person, who made himself liable to the action by not performing his contract, or by doing some illegal act to another man's person or his property, (Gaius iv. 1; 'Instit.' iv. tit. 6); and all these personal actions presupposed circumstances giving rise to some special duty in the defendant. The distinction between the two, however, is more clearly shown in the mode in which the demandant asserted his right, for in the *actio in rem* he stated it in general terms, without the name of any defendant being given (*e. g.*, "Si paret, fundum ex-jure Quiritium Titii esse"). In the *actio in personam* the defendant was individually pointed out ("Si paret Numerium Negidium . . . . . dare oportere"). What were called interdicts in the Roman law, may also be referred to the class of actions *in personam;* but the term *interdictum*, when considered in opposition to *actio*, denoted a kind of action in which the procedure might be more quick and summary than the *actio*. The right of action is nothing more than the right actively to exercise, with the aid of a judge, that power of compelling the performance of, or forbearance from, some positive act with which every right is accompanied, as expressed in the maxim, "Ubi Jus ibi remedium," and in the Roman definition of 'action,' "Nihil aliud quam jus persequendi in judicio quod sibi debetur" (J. 4, 6 pr.)

The English division of actions bears some analogy to the Roman division, but it is much less clearly conceived.

ACTION AT LAW is the proceeding for recovery, through the intervention of the law, of that which is legally due: it has been defined to be "a lawful demand of one's right;" or "the right of a man to prosecute by judicial proceeding that which is his due." The general object of every action is thus to put one party in possession of a right of which he has been injuriously deprived by another. This may be effected, where lands or goods are wrongfully withheld, by the actual delivery of them to the proprietor. In the case of assaults, slander, breaches of contract, or other personal wrongs, the only remedy is to award to the sufferer pecuniary compensation for the injury. For one and all of these purposes the law of England appoints specific forms, by which alone can be obtained those legal remedies, which the law affords the injured party in the infinite variety of disputes and controversies that arise between individuals. Where the wrong is of such a nature that there is detriment to the public as well as injury to the individual, it becomes the subject of a criminal prosecution. For those wrongs in general done by one individual to another, which do not amount to legal crimes, the proper remedy is by action at law. It is true, that in some cases the legal remedy is insufficient, and that the injured party, to obtain proper redress must resort to a suit in Chancery. But the circumstances in which these courts (which administer that branch of our law called equity) must be applied to will be more appropriately considered under another head. [EQUITY.]

Actions in England are usually divided into three kinds, according to the subjects of them; namely, real, personal, and mixed.

Real Actions are so called because they exclusively refer to real property, or subjects connected with land. The word *real* here signifies that the action is in respect of a thing (*res*). In the Roman jurisprudence the expression *in rem* did not mean that the action was in respect of a thing (*res*), but it was a technical mode of expressing the generality of the action, as opposed to *in personam*, which had reference to a particular person or persons. Real actions, then, are brought for the recovery of lands, advowsons, or other hereditaments. They were, in the earlier periods of our history, of constant occurrence; and our ancient books of reports are principally occupied with cases of pleas of land, which, before this country had attained to commercial importance, was the most valuable species of property, and, consequently, the most fruitful source of litigation. From the nicety and inconvenient length of the process, they were almost discontinued, when the action of ejectment was by statute made the only mode of trying title, except in the case of dower to a wife, and a disputed right to the exercise of ecclesiastical patronage. (3 & 4 Wm. IV. c. 27.)

Personal Actions are by far the most numerous class of actions. It is by them that differences respecting debts, promises, and contracts, are settled; and that compensation is sought for personal insults and injuries of almost every description, including even some of the minor crimes and misdemeanours, which are punishable both as crimes and as civil injuries.

Mixed Actions partook of the nature of both, being brought for the recovery of lands, and also for damages,—either for some injury done to the land, or some other wrong, such as the illegal detention of it from the owner.

All real and mixed actions were abolished by 3 & 4 Wm. IV. c. 27, except Right of Dower, Dower, Quare impedit, and Ejectment. The two former are brought by a wife for recovery of her dower; by the third, the right to present to a benefice is tried; and by the fourth, the title to real property is ascertained. The action of Ejectment thus preserved was, however, strictly an Action of Trespass. By the 'Common Law Procedure Act, 1852,' Ejectment, the forms of which have been reconstructed, regains the appearance of a real action.

Personal actions are founded either on contracts or on torts (a term used to signify such wrongs as are distinguishable from breaches of contract), and these torts are usually considered as of three kinds: nonfeazance, or the omission of some act which one is bound to do; misfeazance, or the improper performance of some act which he may do; malfeazance, or the commission of some act which is unlawful. Actions founded on contract are sometimes described as actions *ex contractu*, and those on tort as actions *ex delicto;* a division which, as well as the terms used to express it, is derived from the Roman law ('obligationes ex contractu,' 'obligationes ex delicto:' Gaius, iii. 182).

Actions are either local or transitory: local actions are founded on such causes of action as refer to some particular locality, as in the case of trespass to land; transitory actions are such causes of action as may be supposed to take place any where, as in the case of trespass to goods, assaults, and the like. Real actions are in their nature local; personal actions for the most part transitory. Local actions must be tried in the county where the cause of action arose, and by a jury of that county: transitory actions may be tried in any county, (in general at the pleasure of the plaintiff). When an injury is committed out of England, and its nature is such as to make the action local, no action will lie for its redress in any English court; but if the nature of the injury is such that the action is transitory, such action will lie in the English courts. When the cause of action arose abroad, in a transitory action it was formerly necessary to have recourse to a legal fiction, and to allege that it arose in an English county. This was necessary, because every action must be tried *theoretically* by a jury of the county where the cause of it arose; and hence the fiction, alleging, for instance, an assault in Majorca, "*to wit; in the Ward of Cheap, in the City of London.*" This fiction is now abolished, but the plaintiff in every declaration must specify in the margin, some English county as that in which he intends that the cause should be tried.

As to actions generally, it is to be observed as generally true that the right of action is not assignable, so as to enable the assignee to sue at law in his own name; but in certain cases it is transferred by operation of law. Thus the rights of action of a bankrupt or insolvent pass (with certain exceptions) to the assignees; and upon the death of either of the parties between whom there is a cause of action, the right of maintaining such action survives in general to or against the executors or administrators.

In respect to suits which are more strictly personal, that is, affect only the person, as in the case of an action for slander, the maxim is that they die with the person. By the Common Law this extended to every case of tort; but it is now no longer the rule as regards torts committed in respect of property. The 4 Edw. III. c. 7, empowers executors or administrators to maintain an action for trespass to the goods of the testator or intestate; and by 3 & 4 Wm. IV. c. 42, executors or administrators may maintain an action of trespass for any injury to the real estate of the deceased, which was committed six calendar months before his death, provided the action is brought within one year after his death. The same action may also be maintained against executors or administrators for any injury done by the deceased to the real or personal property of another, if it was done within six calendar months before his death, and the action is brought within six calendar months after the executors and administrators have assumed office. The 9 & 10 Vict. c. 93, also allows an action for damages to be brought by the executor or administrator of a person whose death has been caused by the wrongful act, neglect, or default of another, if the act, neglect, or default would have intitled the party injured to maintain an action if death had not ensued. At Common Law, no such suit was maintainable. By the statute, it is to be for the benefit of the husband, wife, parent, or child of the deceased.

The regular parts of an action at law, that is to say of a personal action, are: 1. the Process, or those proceedings which have for their object the compelling of the defendant to appear; that is, to admit that he has a general intimation of the suit, and is ready to receive more particular notice of its ground and object. This is done by writ of summons served personally on the defendant. 2. the Pleadings, consisting of the *declaration*, in which the plaintiff fully sets out his grievances, the *pleas* on which the defendant answers the declaration by contradicting the allegations contained in it; asserting his own right, or justifying his conduct: to this the plaintiff may reply; and thus the parties may continue to altercate, in legal language, until material questions are distinctly asserted by one party and denied by the other. 3. the Trial, where the questions for decision which are called the *issues* are tried by the jury (or in some rare cases by a judge or the court), who after hearing the *evidence* of both parties, give their *verdict* either for the plaintiff or defendant. 4. the Judgment, which in pursuance of this verdict is pronounced by the court to which the proceeding belongs. 5. the Execution, issued by the court against the person or goods of the unsuccessful litigant, unless there be, 6. an Appeal, by error being brought on the judgment, which ends only in the judgment of the House of Lords.

It ought to be mentioned, that formerly, in all actions of debt, the plaintiff might commence by arresting the defendant where the debt amounted to 20*l*. Arrest on mesne process is now abolished. [ARREST.]

(For further particulars see *Blackstone's Commentaries*, Mr. KERR's ed. v. iii. *passim;* Jacob's *Law Dictionary*. See also as to real actions, DOWER; EJECTMENT; QUARE IMPEDIT.)

ACTION UPON THE CASE. [CASE, ACTION UPON THE.]

ACTION AND RE-ACTION. [MOTION, LAWS OF.]

ACTION, LEAST PRINCIPLE OF, is a name given by Lagrange to a law of motion which he has thus enunciated:—In a system of moving bodies, the sum of the products of the masses of the bodies by the integral of the products of the velocities and the elements of the spaces passed over, is constantly a maximum or a minimum.

The principle, in a limited sense, originated with Maupertuis, who, in the 'Mémoires de l'Académie des Sciences de Paris,' for 1740, designating it the 'Law of Rest,' states that when bodies in motion act upon one another, the sum of the products of the masses by the velocities, and by the spaces described, is a minimum; and from this principle he deduced the laws of the reflexion and refraction of light, and of the collision of bodies. Euler also, in his 'Traité des Isopérimètres' (Lausanne, 1744), showed that when isolated bodies describe curvilinear paths by the action of central forces, the integral of the product arising from the multiplication of the element of the curve by the velocity is always a maximum or a minimum. But the generality of the principle was established by Lagrange, who has extended it to the motion of a system of rigid bodies acting upon one another in any manner whatever; and his first applications of it to the solution of dynamical propositions are contained in the second volume of the 'Mémoires de l'Académie, &c., de Turin.'

The analytical expression of the principle is that $\Sigma m\int vds$, or $\int\Sigma mvds$, is a maximum or a minimum, and consequently that the infinitely small variation of that quantity is zero. It would be more correct to say that the variation is zero, whence, except in peculiar cases, the formula called the *action* is a maximum or a minimum. (Here m is the mass of a body, v its velocity, and ds the element of the space passed over.) But $ds = vdt$ (dt being the element of time;) therefore, $\int\Sigma mvds$ is equivalent to $\int\Sigma mv^2dt$. Now, Σmv^2 is the expression for the active or living force of a finite number of rigid bodies or molecules [VIS VIVA]; and it follows that the principle of 'least action' is the equivalent of the expression that the integral of the product of the vis viva of a system by the element of time, is in general a minimum.

The truth of the 'Principle of least action' may be readily proved from the general dynamical equation [VIRTUAL VELOCITIES], the sum of the terms containing X, Y, and Z, being made equivalent to $\delta(\frac{1}{2}\Sigma m.v^2)$, or to $\Sigma mv\delta v$, conformably to what is shown in the article just quoted; and the whole being transformed agreeably to the process used in the 'Mécanique Analytique' (sect. iii. No. 39). It will be needless, however, to give the details, since, as is observed by Poisson, the use of the principle is only to serve as a rule for forming the differential equations of motion, and these may be obtained at once from the General Equation to which reference has been made above. We have thus given what is sufficient, with reference to the *name* of this principle. But we warn the student that he must look for further explanation in full treatises: all that we say in so brief a space abounds with possibilities of misconception. On the physical view of the principle there are some instructive remarks in Nichol's *Cyclopædia of the Physical Sciences.*

ACTIVE OR LIVING FORCES. [VIS VIVA.]

ACTON BURNEL, STATUTE OF. This statute was passed at Acton Burnel, in Shropshire, at a Parliament held by Edward I., on his return from Wales. Acton Burnel was never even a market-town, and Leland says ('Itin.' vii. 19), that the Parliament was held in a great barn. The truth is, however, that it was held in the great hall of the castle of the Lord Chancellor Burnel, the author, no doubt, of this statute, and also of the 'Statute of Westminster the First,' passed in 1275. Its date is October 12, 1283.

The preamble reciting that merchants "be greatly impoverished because there is no speedy law provided for them to have recovery of their debts at the day of payment assigned;" enables a creditor to bring his debtor before the mayor of London, York, or Bristol, or before the mayor and a clerk appointed by the king to acknowledge the debt, and fix a time for payment. If the debtor neglected to pay his debt at the time appointed, the mayor ordered his chattels and devisable burgages to be sold, to the amount of the debt, by the appraisement of honest men; the moveables being to be delivered to the creditor if no buyer came forward. The most minute directions are given as to the mode of making and recording the acknowledgment, and levying the debt, if unpaid, by execution. If the debtor had no effects, he was to be imprisoned until he or his friends had come to some agreement with the creditor; and the creditor was bound to provide him with bread and water, if he were so poor as to be unable to support himself: but the cost of his maintenance was added to the original debt, and was required to be repaid before the debtor could obtain his release. The creditor might accept sureties or mainpernors, who by this act placed themselves precisely in the same situation as the debtor; but they were not liable till the goods of the principal had been sold and found insufficient.

The Statute of Acton Burnel was further explained, and new provisions added by 13 Edw. I., st. 3, passed in 1285, and called the 'Statutum Mercatorum.' If the debtor failed to make good his payment at the time, he was, if a layman, to be placed at once in prison. If he could not be found, the merchant might have writs to all the sheriffs in whose jurisdiction the debtor had lands; and as a last resource the merchant might have a writ to take the debtor's body. The keeper of the prison became answerable for the debt if he refused to take custody of the debtor. Within a quarter of a year, the chattels and lands were to be delivered to the creditor for sale in payment of his debt. If within the second quarter he did not make terms, all his goods and lands were to be delivered, the latter as if a gift of freehold, to the creditor, to hold until the debt was paid; the debtor being maintained on bread and water by the merchant. Precautions were taken against the debtor fraudulently making over his property. Lands given away by feoffment subsequently to the recognisances were to return to the feoffer. The death of the debtor did not bar the debt; for though the body of the heir could not be taken, his lands were answerable as much as during the lifetime of the debtor. Jews were excluded from the benefits of the statute. ('Stat. of Realm.' i. 98.)

Reeves ('Hist. of the English Law," ii. 162) observes that the above statute may be "considered as contributing to extend the power of alienating land." Any common creditor by judgment was empowered by the Statute of West. 2, to take half the debtor's land in execution, "but a merchant who had resorted to this security might have the whole." He adds that "a recognisance acknowledged with the formalities [here] described was in after times called a statute merchant;" and "a person who held lands in execution for payment of his debt, as hereby directed, was called tenant by statute merchant." Barrington ('Obs. on the more Ancient Statutes,' p. 119), states that in 1536 an ordinance of Francis I. was issued, which very much resembled the statutes merchant, and shows, he says, "the more early attention paid to commerce in this country."

It need scarcely be added that the Statute of Acton Burnel has long been practically obsolete.

ACTS OF SEDERUNT, in the law of Scotland, are rules made by the Lords of Council and Session, the Judges of the Court of Session, by virtue of Acts of Parliament for regulating the procedure and forms of administering justice. These are called Acts of Sederunt because they are made by the Lords of Session *sitting* in judgment.

ACTS OF THE APOSTLES. The authenticity of this book has not been doubted; it constitutes the second part of the Gospel according to St. Luke, which he dedicated to Theophilus (Luke i. 1; Acts i. 1). The Acts belong to the *Homologoumena*, or those canonical books which were by all parties recognised as genuine (Euseb., 'Hist. Ecclesiastica,' iii. 25). The Severians (Euseb., 'Hist. Eccles.,' iv. 29) and the Manichæans (Augustin. 'Epist.' 23) acknowledged the authenticity of the Acts, although they rejected, for doctrinal reasons, their authority. Although the authenticity of the Acts was well established, they were less read among the lower classes; and accordingly Chrysostomus, at the end of the 4th century, wrote at the commencement of his 'Commentary to the Acts,' "Many do not know even the existence of this little book, nor him who wrote and composed it."

The time at which St. Luke wrote the Acts may be gathered from the following circumstances:—The arrival of St. Paul in Rome took place in the spring of about the year A.D. 63. St. Paul, in his Epistles to the Colossians (iv. 14), to Timothy (2nd ep. iv. 11), Philemon (ver. 24), testifies to St. Luke being with him in Rome; and as this arrival is mentioned in the Acts, they must have been written after the year 63; and since the death of St. Paul, about the year 68 or 69, is not mentioned by St. Luke, the Acts were probably composed and circulated before this date. Theophilus, to whom the Acts were dedicated, may be considered as the representative of the inquiring heathen; consequently, it was proper that the Acts should be written, as they are, in the Greek language; and the style, like that of the Gospel of St. Luke, is much purer than most of the other writers in the New Testament, the few Hebraisms generally occurring in the reproduced speeches of some of his introduced personages.

The explanations and commentaries on the Acts of the Apostles are numerous from the times of the early fathers and in foreign languages, particularly the German. In England, all the commentators have bestowed much attention on this portion of the New Testament; and Paley subjected it to a searching examination in his 'Horæ Paulinæ,' in connection with Paul's Epistles, a labour which has been successfully continued by the Rev. W. J. Conybeare, M.A., and the Rev. J. Howson, in the 'Life and Epistles of St. Paul,' of which a second edition was published in 1856. For the dates of the recorded events there is a variance of opinions. Those of Mr. Greswell ('Dissertations,' &c., 1837), and Dr. Anger ('De Temporis in Actis App. Ratione,' Lips., 1833) are probably as close an approximation to correctness as can be made; the two very nearly agree, and their difference with Usher, Pearson, Michaelis, and others is, that Mr. Greswell fixes the Ascension in the year A.D. 30, while most of the others give the date as A.D. 33; that he assigns the stoning of Stephen, the conversion of St. Paul, and the first journey of St. Paul to Rome, to A.D. 27, 38, and 41 respectively, while the others give A.D. 34, 35, and 38,—the latter appearing to be more consistent with the data afforded by St. Paul himself in Gal. ii. as compared with Acts xi. 12. The other assigned dates are—St. Paul's second journey to Jerusalem, A.D. 44; the third journey (Acts xv.), A.D. 48; his arrival at Corinth, A.D. 52; fourth journey to Jerusalem (Acts xviii.), A.D. 54; his abode at Ephesus, A.D. 53—55; fifth journey to Jerusalem (Acts xxi.), A.D. 56; arrival at Rome, A.D. 61.

Messrs. Conybeare and Howson differ slightly from this, fixing the conversion of St. Paul in A.D. 36, his first journey to Jerusalem in A.D. 38, and the second in A.D. 45; but they all agree in fixing the visit in the year of the famine. The date of the fifth journey to Jerusalem also is given by these gentlemen as A.D. 58 instead of A.D. 56.

It may be worth mentioning, that the title of the book is an arbitrarily and not happily imposed one; the Acts of the Apostles are confined to those of Peter and of Paul, of the martyrdom of James, with a slight mention of the writer. The book was probably interrupted by the death of the writer, as it terminates abruptly, and records the death of neither of the principal personages.

ACTUARY, a word generally used to signify the manager of a joint-stock company under a board of directors, particularly of an insurance company: whence it has come to stand generally for a person skilled in the doctrine of life annuities and insurances, and who is in the habit of giving opinions upon cases of annuities, reversions, &c. Most of those called actuaries combine both the public and private part of the character. The actuaries now form by themselves a separate profession.

The name has acquired a legal character since it was recognised in the Friendly Societies Act of 1819, which enacted that no tables were to be adopted in any Friendly Society, unless the same should have been approved by "two persons, at the least, known to be professional actuaries, or persons skilled in calculation." The Committee on Friendly Societies of 1825 reported that "petty schoolmasters or accountants, whose opinion upon the probability of sickness and the duration of life is not to be depended upon," had been consulted under this title, and recommended that the actuary of the National Debt Office should be the only recognised authority for the purposes above-mentioned, in which recommendation the Committee of 1827 joined. The 10 Geo. IV, c. 56, made no alteration, but by the 9 & 10 Vict. c. 27, the power of certifying tables is confined to the actuary of the National Debt Office, or an actuary of not less than five years' standing in some public insurance company.

The registrar of the Lower House of Convocation is called the actuary. Bishop Gibson says that he is an officer of the archbishop, the president of the convocation, and cites as follows, from the fees established by Archbishop Whitgift (1583-1603) for the vicar-general's office: "Feoda Actuario Domus Inferioris Convocationis solvenda." (Gibson's *Synodus Anglicana*, 1702.)

The word actuary is from the Roman *actuarius*, which was used in various senses, but its earlier and more common meaning was short-hand writer.

ACUPUNCTURE, a term used to denote the insertion of a needle into the skin or flesh. Acupuncture is an operation which has been long in use in eastern countries, and which appears to have been adopted there from the notion that several diseases attended with severe pain arise from air or vapour pent up in the body, to which a puncture with a needle affords an outlet, and thereby removes the malady. Europeans travelling in those countries several times witnessed the practice, and were struck with the results; but either their reports were not credited, or the operation appeared to the physicians and surgeons of Europe so unpromising, that upwards of a century elapsed after the knowledge of it was familiar to many European practitioners before a single trial of it was made. As long back as the year 1679, a medical officer in the East India Company's service states that a guard of the Emperor of Japan, appointed to conduct the English to the palace, was seized with violent pain of the abdomen, attended with vomiting, in consequence of having drunk a quantity of iced water when heated. After trying in vain to relieve his complaint by taking wine and ginger, and conceiving that his suffering arose from air or vapour pent up in the walls of the abdomen, to which vapour the insertion of needles into the skin would afford an exit, he underwent the operation of acupuncture in the presence of the narrator, which was performed in the following manner:—He laid himself upon his back, placed the point of a needle upon his abdomen, struck its head with a hammer once or twice to make it pass through the skin, turned it round between the forefinger and thumb till it entered to the depth of an inch, and then, after about thirty respirations, withdrew it, and pressed the puncture with his fingers to force out the imaginary vapour. After having made four such punctures, he was instantly relieved, and got well. Some years afterwards, a physician, who accompanied a Dutch embassy to Japan, confirmed this account, by the statement that the Japanese are in the constant habit of performing this operation in various disorders attended with acute pain, and that he himself frequently witnessed the instantaneous cessation of the pain as if by enchantment. No further notice appears to have been taken of this mode of treatment in Europe for upwards of a century, when it was alluded to by the celebrated Vicq-d'Azyr in the 'Encyclopédie Méthodique,' merely for the purpose of congratulating the world that the statements of Ten Rhyne and Kæmpfer, the physicians who had given the first accounts of it, had not induced any European physician or surgeon to practise it. In the year 1810, however, some trials of it were made by Dr. Berlioz, a physician of Paris, who found, or fancied he found, it so efficacious a remedy, that he was induced to employ it very extensively, and many French practitioners imitated his example with the same apparent results. It has been subsequently tried in England, and sufficient experience of it has now been obtained to prove that the operation itself is attended with little or no pain, and that it may be employed at least with safety, if not with advantage.

There are two cases in which it seems likely to be beneficial,—first, in painful local affections unattended with change of structure in the part diseased, and without local inflammation or general fever,—and, secondly, in that species of dropsy termed anasarca, in which the water is accumulated in the cells of the cellular membrane that lies immediately beneath the skin. It is probable that all the cases of the first class consist of disordered states of the nerves of the parts affected [NEURALGIA]. There cannot be a question that this remedy has proved beneficial in cases of this kind sufficiently often to warrant the trial of it, whenever these disorders do not yield to the ordinary modes of treatment; and under these circumstances there is the greater reason for resorting to it, since the operation occasions no pain, and since no evil consequence of any kind has ever been known to result from it. But if the part affected be inflamed, and more especially if there be any degree of febrile action in the system, the acupuncture of the part will certainly do no good, and will very likely produce mischief.

In anasarca a few punctures made with the needle will allow a ready exit to the fluid, which may continue to drain during several days in succession; and when this is the case, it invariably affords relief, and sometimes saves, and oftener prolongs, life. Scarification is a remedy of the same kind in ordinary use, but the inflammation that results from this practice is sometimes severe, and occasionally runs into mortification. Acupuncture is affirmed by many who have made trial of it to be equally effectual, and to be much less apt to be attended with these evil consequences.

The needles employed in oriental countries are always made of the purest gold or silver; those of gold are preferred, and great care is taken to obtain them well tempered. In China their manufacture is a distinct occupation, understood by few, and those few are licensed by the emperor. Some of these needles are fine, about four inches in length, with a spiral handle, for the purpose of more easily turning them, and are kept by means of a ring, or a piece of silk thread, in grooves, each capable of holding one needle: the grooves are formed in each side of a hammer, usually made of the polished horn of the wild ox, ivory, ebony, or some other hard wood; the hammer is rather longer than the needle, and has a roundish head, covered on the side that strikes with a piece of leather, and rendered heavier by a little lead within. The needles employed in Europe are of steel, long and fine, and furnished either with a nob of sealing-wax at their head, or, what is more convenient, a little handle of ivory or wood, screwing into a sheath for the needle. They are best introduced by a slight pressure, and a semi-rotating motion, between the thumb and forefinger, and withdrawn with the same motion. In cases of neuralgic pain the needle should be allowed to remain in from a quarter of an hour to two hours. It would appear, that in cases of this kind, a number of needles introduced, and hastily withdrawn, is not as effectual as the introduction of a single needle that is allowed to remain for the space of a couple of hours. When the only object is to afford an exit to the fluid collected in anasarca, of course the mere puncture is sufficient; there is no use in allowing the needle to remain.

A modification of this operation has been recently proposed in cases of neuralgia. A tubular needle, connected with a syringe, is introduced into that part of the course of the diseased nerve which is most painful on pressure, and a weak solution of morphia is injected into the tissues. In many cases this has been followed with instantaneous relief. It requires, however, care, as, in some cases, profound narcotism has been induced.

AD LIBITUM, Latin, or *ad lib.* in music, denotes that the performer is at liberty to pause, or to introduce any cadence or addition of his own, according to his judgment. An accompaniment is said to be *ad libitum*, when it is not essential, and may be either used or omitted as circumstances may require, without materially affecting the composition.

ADA'GIO, in Music, an Italian adverb, signifying *slowly, leisurely,* and used to indicate the slowest movement in music. It has long been the custom to point out the quickness or slowness, as also the manner or character, of a piece of music, by some Italian word, placed at the beginning of the composition. These are sometimes very inadequate to the purpose, and much is commonly left to the judgment of the performer. The use of the metronome [METRONOME], fixes the intention of the composer as regards movement, that is to say, quickness or slowness. With respect to style, to the passion meant to be expressed, much must still depend on the taste and intelligence of those to whom the execution of a work is intrusted.

The five principal terms denoting the degrees of motion, beginning from the slowest and proceeding to the quickest, are—*Adagio*, very slow; *Largo*, slow; *Andante*, a moderate time; *Allegro*, quick; *Presto*, very quick. Other terms relating to slowness or quickness are but modifications of the above.

These words are also used substantively: thus we say, an 'Adagio' of Haydn; an 'Andante' of Mozart, &c.

ADAR, the twelfth month of the Hebrew year. (Esther, iii. 7.) The name of this month is Chaldee, and does not occur in the earlier books of the Bible, where the months are usually designated by their numerical order.

In the Jewish calendar, Adar is the sixth month. In ecclesiastical computations, it is still the last of the year. As the year being composed of twelve lunar months is shorter by about eleven days than a true year, an additional month is periodically inserted after Adar, and is called Ve-Adar, or another Adar. This intercalation occurs seven times in nineteen years.

Adar may begin as early as the 1st of February, or as late as the 3rd of March. In years of twelve months, there are twenty days in Adar; in those of thirteen months, there are thirty days in the month. A fast is observed by some Jews in memory of the death of Moses, on the 7th day of the month; another, on the 9th, for the schism in the schools of Shammai and Hillel. On the 13th day of the month, the Fast of Esther is kept by the whole Jewish nation. This fast is said to have been instituted in memory of the intended destruction of the Jews in the Persian empire on that day. (Esther, iii. 13.) If the 13th day should be a Saturday, the Fast of Esther is celebrated on the preceding Thursday: all other fasts (except the Great Fast of Expiation, which is never postponed) are, in similar cases, held on the Sunday following. The feast of Purim, which lasts two days, belongs to the 14th and 15th of the month, in memory of the defeat of the plans laid for destroying the Jews. (Esther, ix. 15—21.)

In the years in which the month Ve-Adar is inserted, the Purim and the Fast of Esther belong to that month; and the 14th of Adar is called the First or Little Purim. It appears, then, that in the intercalary year, it is the first Adar that is really the intercalary month, as the festivals remain to Ve-Adar. (Ideler, 'Lehrbuch der Chronologie,' Berlin, 1831.) The festival in honour of the dedication of the second Temple, is kept by some Jews on the 16th, and by others on the 23rd of this month. There is no exact account of the day of dedication; the temple was completed on the 3rd day of the month. (Ezra, vi. 15.)

Adar is the name of the seventh month of the Syro-Macedonian year, which coincides nearly with our March.

ADDISON'S DISEASE. [KIDNEYS, DISEASES OF.]

ADDITION, from the Latin *addo* to *give to*, is the putting together of two or more magnitudes into one. In arithmetic and algebra it also signifies the most convenient method of doing this, so that the sum or collection of added quantities may be counted or reckoned in the same manner as the parts of which it was composed. The sign of this operation is $+$, which is generally pronounced *plus*, the Latin for *more*. Thus $a+b$ directs us to add the number denoted by b to that denoted by a, and represents the sum of a and b.

Addition of whole numbers in arithmetic is performed partly by memory, partly by the aid of the decimal system of numeration. [NUMERATION.] The sum of every two numbers, each of which is not greater than 9, must be remembered; from whence the addition of such numbers as 28 and 9, 33 and 6, &c., can be performed in the head. The further process is the same in principle, whether the several quantities to be added together be tens, hundreds, &c., pence, shillings, &c., or any other denomination. Presuming that no reader will be ignorant of the ordinary methods, we show the general principle for all cases in the following question, in which any lines of headings may be taken:—

Hundreds. Shillings. Roods.	Tens. Pence. Perches.	Units. Farthings. Sq. Yards.
b	c	d
f	g	h
l	m	n

Add together d, h, and n, and if they be units, convert the sum into tens and units; if farthings, into pence and farthings, &c., meaning thereby, take the greatest number of tens out of all the units, of pence out of all the farthings, &c., in $n+h+d$, and write what is left under n. *Carry* (as it is called) the tens, pence, &c., to the next column on the left, and add successively m, g, and c to them, taking the hundreds, shillings, &c., as the case may be, from the result, and writing the remainder only under *m*. Carry the hundreds, &c., to the next line on the left, and so on.

The addition of fractions is, in principle, as follows: We cannot immediately express the sum of one-half of a foot and one-third of a foot otherwise than by writing $\frac{1}{2} + \frac{1}{3}$ of a foot. But if we recollect that *one-half* is *three-sixths*, and one-third is *two-sixths*, it is evident that the sum of one-half and one-third is *five-sixths*. The rule, therefore, is: Reduce the various fractions to others of equal value, and having the same denominator, add the numerators retaining the denominator: or, multiply every numerator by every denominator, except its own; add the results, which gives the numerator of the sum: multiply all the denominators together for the denominator of the sum. Thus, for—

$$\frac{2}{3} + \frac{3}{7} + \frac{4}{5} \text{ which is } \frac{199}{105}$$

$$\left.\begin{array}{r} 2 \times 7 \times 5 = 70 \\ 3 \times 3 \times 5 = 45 \\ 4 \times 3 \times 7 = 84 \end{array}\right\} \text{Add}$$

$$\begin{array}{rl} & 199 \text{ numerator} \\ 3 \times 7 \times 5 = & \overline{105} \text{ denominator.} \end{array}$$

To add decimal fractions, arrange them so that the decimal points shall fall under one another, proceed as in common addition, and let the decimal point in the sum total be placed under the other decimal points:—

$$\begin{array}{r} 2{\cdot}61 \\ {\cdot}04 \\ {\cdot}118 \\ \hline 2{\cdot}768 \end{array} \qquad \begin{array}{r} 14{\cdot}103 \\ 1{\cdot}04 \\ 118\phantom{{\cdot}000} \\ \hline 133{\cdot}143 \end{array}$$

To add algebraical quantities, write them all one after another, without changing any sign, and connect the terms, which before had no sign, with the rest, by the sign $+$. Thus $a + b$ and $a - 2b$ added, give $a + b + a - 2b$. This is the sum, which may be reduced to a simpler form, by observing that b subtracted twice and added once, is equivalent to b subtracted once, and that a is added to a. The expression then becomes $2a - b$.

When the quantities are fractional, the preceding rule follows the application of another similar to the rule in fractional arithmetic. Thus, for—

$$\frac{a}{a+b} + \frac{b}{a-b} \text{ the sum of which is } \frac{a^2+b^2}{a^2-b^2}$$

$$\left.\begin{array}{r} a \times (a - b) = a^2 - ab \\ b \times (a + b) = ab + b^2 \end{array}\right\} \text{Add}$$

$$\begin{array}{rl} & a^2 - ab + ab + b^2 \\ \text{or} & a^2 + b^2 \text{ numerator} \\ (a + b) \times (a - b) = & \overline{a^2 - b^2} \text{ denominator.} \end{array}$$

ADDITION OF RATIOS. A phrase which may, perhaps, at first, puzzle the mathematical student who reads old books, and which we therefore explain here. Take two ratios or proportions, say 3 to 7 and 5 to 9; the ratio of 3×5 to 7×9, or of 15 to 63 was formerly said to be the *sum* of the ratios of 3 to 7 and 5 to 9. Similarly the ratio of 25 to 4 was said to be *double* of the ratio, or the *duplicate ratio*, of 5 to 2; that of 125 to 8, *triple* or the *triplicate ratio*, and so on. [RATIO; LOGARITHM.] The sum of the first ratios in any modern work would probably mean $\frac{3}{7} + \frac{5}{9}$; but the term 'sum of the fractions,' would most likely be used in preference.

ADHESION. This term has generally been employed to denote the property by which two solids, a solid and a fluid, two solids and an interposed fluid, or two fluids, remain attached to each other when their surfaces are brought into contact. Adhesion may, in some instances, be considered as being but little if at all different from cohesion, and dependent upon the same cause, while, in other cases, it appears to be connected with, and probably to a considerable extent derived from, chemical affinity. When, for example, two surfaces of lead are pressed together, the adhesion resembles mere cohesion, it acts at insensible distances like that power, and no change of properties ensues in the metal. If, however, the surface of a piece of lead is put into contact with mercury, the two metals act upon and combine with each other, and an amalgam is produced by virtue of the chemical affinity existing between these two metals. There are other instances in which the adhesion is not distinctly to be referred to cohesion, and in which it certainly does not depend upon chemical affinity, as when a plate of glass adheres to the surface of mercury, or when liquids rise in small tubes by capillary attraction.

Among the earlier attempts to determine the force of cohesion are those of Dr. B. Taylor, in a paper on Magnetism ('Phil. Trans.' 1721). He performed various experiments to ascertain the force of adhesion between wood and water, by determining the force in weight required to separate them. He found it to be directly as the surface, and that a square inch of wood required fifty grains to raise it from the surface of the water.

M. Achard ('Berlin Memoirs,' 1776) made a vast number of experiments on the force of adhesion between plates of glass of different diameters, and many liquids, and upon the adhesion of twenty different substances with as many liquids. It had been supposed that adhesion was derived from atmospheric pressure, but M. Achard found that by varying the pressure no change occurred in the adhesive force of glass and water; and that the adhesion of fluids to solids was uniformly in the inverse ratio of the temperature. The diminution in the force of adhesion by increase of temperatures was attributed by Guyton de Morveau to the rarefaction of the fluid by heat, and the consequent reduction of the points of contact in the same space.

As the surfaces of the solids employed by Dr. Taylor and by M. Achard must have been wetted by the liquids, it has been objected to their experiments, and especially by M. Dutour in the 'Journal de Physique,' that they do not prove any adhesion between the solid and the liquid, but cohesion between the two portions of the liquid which have been separated. If this objection be valid, then those only can be considered as proper cases of adhesion, in which no particle of one substance remains with the other after the separation of their surfaces, as when glass is separated from mercury; M. Dutour found that a disc of glass 11 lines (French) in diameter adhered to mercury with a force of 194 grains.

M. Guyton published in 1777, in his 'Elémens de Chimie,' a series of experiments on the force of adhesion between eleven metals and mercury; his method was as follows: The metals were made chemically pure, circular, and one inch in diameter; they were all of the same thickness, and were suspended from a ring in the centre at the arm of an assay-balance and counterpoised; the surface of the mercury was then brought up to the plates, and the mercury was changed after each experiment: the weights required to detach them were as follow:—

	Grains.		Grains.
Gold	446	Zinc	204
Silver	429	Copper	142
Tin	418	Antimony	126
Lead	397	Iron	115
Bismuth	372	Cobalt	8
Platinum	282		

In these experiments the phenomena of adhesion appear to depend upon the degree of chemical affinity existing between the mercury and the metals applied to its surface. If the affinity were weak, the two surfaces would separate by the application of a slight force. Indeed, M. Guyton himself considers that the weight required to separate the different metals from mercury may directly express their affinity for it. It will be evident on a moment's consideration that the degree of adhesion is perfectly independent of the densities of the different metals.

The sixty-third volume of the 'Philosophical Magazine' contains a paper by Mr. Bevan, in which the subject of adhesion appears to be considered in a point of view which had previously excited but little attention, viz., the real force of adhesion of different nails when driven into wood of different species; the weight, without impulse, necessary to force a nail a given depth into wood, and the force required to extract the same when so driven. The term adhesion in this case is applied to the force, whether arising from friction, or cohesion, or partly from both, with which wood resists the drawing out of a nail. Mr. Bevan has given a table of the adhesion, &c. of different kinds of nails when driven into dry Christiania deal; in this table it appears that a sixpenny nail, 73 to the lb., $2\frac{1}{2}$ inches long, forced $1\frac{1}{2}$ inch into the wood, required 327 lbs. weight to extract it; the percussive force required to drive the sixpenny nail to the depth of one inch and a half into the dry deal, with a cast-iron weight of 6·275 lb., was four blows or strokes falling freely through the space of twelve inches, while the steady pressure required to produce the same effect was 400 lbs. With different kinds of timber the results varied greatly, and Mr. Bevan concludes that a sixpenny nail driven two inches into dry oak, would require a force of more than half a ton to extract it by steady pressure. Mr. Bevan ('Phil. Mag,' and 'Annals of Philosophy,' vol. ii. p. 291) has also determined the force required to draw screws out of different kinds of wood; the screws used were about two inches in length, ·22 diameter at the exterior of the threads, ·15 diameter at the bottom, the depth of the worm or thread, being ·35, and the number of threads in one inch = 12. These screws were passed *through* pieces of wood, exactly half an inch in thickness, and drawn out from the following dry woods by the annexed weights, beech 460 lbs., ditto, 790 lbs., ash 790 lbs., oak 760 lbs., mahogany 770 lbs., elm 655 lbs., sycamore 830 lbs. The force required to draw similar screws out of deal and the softer woods, was about half the above.

About twenty years ago, Professor W. R. Johnson undertook a series of experiments on the adhesion of iron spikes of various forms, when driven into different species of timber. The results of his experiments were published in the 'Franklin Journal.' This inquiry was important from the great use of spikes in the construction of railroads in America, where the cheaper flat rail was preferred to the edge rail, and was fastened to wooden sleepers by means of spikes. Whenever the speed of a train was suddenly checked by the break, the friction of the wheel tended to drive the rail lengthwise, and thus to force all the spikes with which it was fastened into closer contact with the ends of the fibres which had been cut through in driving them; and, as this partial or total dragging of the wheels may take place sometimes in one direction and sometimes in the other, the spikes must be subjected to alternate impulses on opposite sides. Indeed, the ordinary action of the common locomotive produces a constant succession of these opposite dragging forces, the driving-wheels of the engine urging the rails backward while the train tends to urge them forward. Professor Johnson has seen rails entirely detached on a line where the transit was all in one direction, and where the cars descended by gravity, while in other cases the inclined position of the heads of the spikes showed that they were pressed into an oblique or leaning position in the wooden sill. The mode of performing the experiments was to drive each spike to a certain distance above its cutting edge into the edge of a piece of plank or scantling, and to draw it out by a direct longitudinal strain by means of a suitable apparatus. This consisted of a strong band or strap of iron connected with a weighing-beam, which held the piece of plank, and a clasped pincers, with a suitable jaw, for taking hold of the head and projecting part of the spike; this was attached to the opposite part of the machine, which, being tightened by a strong screw, held the spike firmly while the application of weights upon the longer arm of the lever drew the timber away and released the spike. Care was taken to cause the strain to pass through the axis of the spike, and, by a very gradual application of weights, to avoid surpassing that force which was just sufficient for its extraction.

The first experiments were with Burden's patent square spikes with a cutting edge for driving across the grain of the timber. This spike was ·375 inch square, and was driven into a sound plank of seasoned Jersey yellow pine to the depth of $3\frac{3}{8}$ inches; the force required to extract it was 2052 lbs.; the weight of the part driven into the wood was 866 grs. Troy. The second trial was upon a flanched, grooved, and swelled spike, having the grooves between two projecting wings or flanches on the same sides as the faces of the cutting edge; the other two sides were planes continuing to the head. This spike was driven into the same kind of wood as before, and the weight required for extracting it was 1596 lbs.; the weight of the part driven in was $708\frac{1}{4}$ grs. The cutting edge was ragged and irregular, and the distance to which it was driven was $3\frac{3}{8}$ inches as in the first trial. "To know the relative values of the two forms of spikes, we have but to divide the weight required for the extraction of each by the number of grains in the part which had been buried in the wood. Thus, 2052÷866 =2·37, and 1596÷708·25=2·112. Hence, the plain spike had an advantage over the swelled and grooved one in about the proportion of 23 to 21. It should be mentioned, also, that the plain spike was drawn out by a very gradual addition of force; whereas the force of 1596 lbs. drew the grooved spike immediately after its application. In the first trial, an attempt was made to detect any yielding or gradual retreat of the spike before the final start, but none was perceived."

The third and fourth experiments were made with the same spikes respectively as the first and second; but instead of yellow pine the timber employed was thoroughly seasoned white oak. The plain spike, driven $3\frac{3}{8}$ inches into that timber, required for its extraction a force of 3910 lbs., and, as before, exhibited no signs of movement until the instant of starting, when it suddenly came out about a quarter of an inch, or as far as the range of motion and the elasticity of the machine would permit. The flanched, swelled, and grooved spike, driven $3\frac{3}{8}$ inches into another part of the same piece of plank, from which the plain one had been extracted, was drawn out with a force of 3791 lbs. A slow motion, to the extent of $\frac{1}{25}$ or $\frac{1}{20}$ of an inch, was in this trial perceived to precede the starting of the spike, and was accompanied by a gradual protrusion of the fibres of the timber immediately around the iron. In these experiments, though the plain spike bore the greater absolute weight, yet, when the weight of metal is considered, it is seen that the relative values of the two are 4·515 in the plain, and 5·354 in the grooved form. "Hence, it appears that in yellow pine the grooved and swelled form was about five per cent. less advantageous than the plain, while in the seasoned oak the former was $18\frac{1}{2}$ per cent. superior to the latter. It is also apparent that the advantage of seasoned oak over seasoned yellow pine, for retaining spikes, is, by a comparison of experiments 1 and 3, as 1 to 1·9; and by a comparison of 2 and 4, it is as 1 to 2·37." Other experiments were also tried upon a spike of given form, which was driven a certain distance into different timbers, and the order of retentiveness beginning with the highest was as follows: 1. Locust; 2. white oak; 3. hemlock; 4. unseasoned chestnut; 5. yellow pine. The results of numerous experiments are given in tables, from which it appears, among other conclusions, that the fibres of the wood should press the faces of the spike as nearly as possible in their longitudinal direction, and with equal intensities, throughout the whole length of the spike. The following arrangement gives the spikes in the order of their ratios of retention to weight:—

1. Narrow flat	7·049
2. Wide flat	5·712
3. Grooved, but not swelled	5·662
4. Grooved and notched	5·300
5. Grooved and swelled	4·624
6. Burden's patent	4·509
7. Square hammered spike	4·129
8. Plain cylindrical	3·200

In promoting the adhesion of surfaces, it is not unusual to make one of the solids semi-fluid or ductile by heat or otherwise, and on returning to its hard state, provided it does not crystallise, the adhesion is not diminished unless indeed the unequal contractions of the two substances by the same reduction of temperature forces them apart. The fitness of different cements for joining different substances depends chiefly on their expanding equally with those substances. Metals, being generally more expansible than other solids, will not adhere to ordinary cements, but require metallic ones, or *solders*, as they are called, and these must be so compounded as to have nearly the same rate of expansion as the metals which they are intended to unite. "Glass and stones, being both less expansible and less various in their rates of expansion, adhere to a greater variety of substances; and light porous solids, being very little affected by change of temperature, adhere still more generally to those of the same kind, which may be softened by heat or liquid solvents, and return to the solid state gradually and without tendency to crystallise. The most universally adhesive bodies (as pitch) are those which retain, even at low temperatures, a certain ductility by which they may readily yield to the various expansions and contractions of the rigid bodies in contact with them; and the rigid bodies most readily made to adhere are the worst conductors of heat, because they cannot undergo very sudden changes of temperature or bulk, and so allow time for the adhering body to accommodate itself. The non-adhesiveness of animal membranes is very remarkable, and probably a provision for their cleanliness and freedom from foreign matter. Crystallisation, by requiring a body while solidifying to obey with rigour certain internal laws of its own, is a great bar to adhesion. The adhesion of two solids is generally stronger than the cohesion of at least the weaker one. Hence, if two pieces of wood be glued, gummed, or pasted together, and then separated, a layer of cement adheres to each; and if there be a bank-note in the midst of the cement, it will be split into two layers, simply because its own cohesion is less than that of the cement, or of the wood, or the adhesion between the cement and either wood or paper." *

Adhesion between solids is the chief cause of that resistance to motion which is termed *friction*. Friction is generally greater between similar kinds of matter than between different kinds. Thus, an iron axle experiences more friction when moving in an iron socket than in a brass one, and in order to reduce the amount of friction in machinery, it is usual to interpose between the grinding surfaces some such lubricant as plumbago, or grease, the particles of which have but little tendency to cohere.

The adhesion of caoutchouc fits it for a variety of applications. Its complete adhesion to glass makes it useful for stopples, and enables the chemist to make air-tight and flexible joints in his apparatus. It is also well adapted, by its adhesion, to be employed for bands for driving machinery. Its adhesion is ingeniously employed in the manufacture of *cards*, used for carding cotton. A cotton-card consists of a wire-brush with a flexible back, the latter being supplied at one time by leather; but as the holes through which the wire teeth were passed, became enlarged by use, the teeth were no longer held in their places; but by making the flexible back of two pieces of linen with an interposed layer of caoutchouc, the adhesion of the latter to the wire caused it to follow the teeth when any strain was put upon them, and by its elasticity restored each tooth to its proper position when the strain was removed.

ADIPIC ACID (2HO, $C_{12}H_8O_6$). When oleic acid, spermaceti, fat, or wax is acted on by nitric acid, several new acids are formed, and amongst them adipic acid. It crystallises in hemispherical, radiated tufts, which fuse at 266°, and distils without decomposition. It is very soluble in hot alcohol or ether, and also in boiling water.

ADIPIC ETHER ($C_{12}H_8O_6 + 2C_4H_5O$), the compound of adipic acid with oxide of ethyl. It is an oily body, possessing a powerful odour of rennet apples. Its sp. g. is 1·001, and it boils at 446°.

ADIT. [MINING.]

ADIPOCIRE, a substance so named from *adeps*, fat, and *cera*, wax, because it possesses the properties partly of fat and partly of wax. It is a body of a peculiar nature, being intermediate between fat and wax, and bearing a close resemblance to spermaceti. This name was given by M. Fourcroy in 1786 to the substance in question, which he discovered on examining a piece of human liver that had remained for ten years exposed to the air in the laboratory of M. Poultier de la Salle. In the same year Fourcroy had the opportunity of observing an accumulation of adipocire on a scale of prodigious extent, under circumstances of a peculiar nature, which are highly curious. There was in Paris an immense burial-ground, called La Cimetière des Innocens. This place had been the receptacle of the dead for a considerable part of the population of Paris for several centuries. On account of some improvements in the neighbourhood it was determined to remove this cemetery. The number of burials in this place had amounted to some thousands annually. The bodies were deposited in pits or trenches about thirty feet deep; each pit was capable of holding from twelve to fifteen thousand bodies; and as the pits became full they were covered with a few feet of earth. The extent of the whole area was about seven thousand square yards, and this space became at last occupied by a mass which consisted almost entirely of animal matter, rising several feet above the general level of the soil. Scientific men were especially charged by the government to direct the precautions requisite for securing the health of the workmen in removing this immense mass of putrefying animal matter; among whom were Fourcroy and Thouret,

* Tomlinson's 'Cyclopædia of Useful Arts,' &c., Article ADHESION.

the latter of whom has given a most interesting account of the circumstances attending the opening of the ground; and the former an analysis of the new and singular object that presented itself for investigation. The most remarkable change was found in the bodies that had been heaped together in the trenches. The first of these trenches opened in the presence of Fourcroy had been closed for fifteen years. The coffins were in good preservation; the covers being removed, the bodies were observed at the bottom, leaving a considerble distance between their surface and the cover, and flattened, as if they had suffered a strong compression; the linen which had covered them was slightly adherent to the bodies; beneath the linen was found nothing but irregular masses of a soft ductile matter of a grey-white colour, resembling common white cheese, the resemblance being more striking from the prints which the threads of the linen had made upon its surface. The bones, which were surrounded by this matter, had no solidity, but were readily broken by sudden pressure. The head was environed with this peculiar matter; the face was no longer distinguishable; the mouth was disorganised; no trace remained of the viscera of the thorax and abdomen, which were all confused together and converted into this fatty matter; and this was also invariably the case with the brain. None of this matter was found in bodies isolated from each other, but only in those accumulated in the common graves. From various observations it was found that this fatty matter was capable of enduring in these burying-places for thirty or forty years, but that ultimately it became corrupted and was dissipated.

This substance thus presented for examination under such remarkable circumstances, is considered by M. Fourcroy as an ammoniacal soap, formed of a peculiar oil combined with ammonia. Its properties are,—that it melts at about 130° Fahr.; by a strong heat it is decomposed with the evolution of ammonia; alcohol acts only slightly upon it at common temperatures, but when boiling dissolves about one-fourth of its weight, the greater part of which separates on cooling in small acicular crystals; lime, potash, and soda decompose it with the evolution of ammonia; it is decomposed by nitric acid with the production of nitric oxide, and by sulphuric acid with the development of carbon. M. Chevreul ('Recherches sur les Corps Gras') finds that adipocire consists of a large quantity of margaric acid, and a small quantity of oleic acid, combined with a little ammonia, potash, and lime.

A'DJECTIVE, in Grammar, the name of one of the parts of speech, or one of those great classes into which, for the sake of convenience, grammarians have distributed the words of a language. The term *adjective*, which is of Latin formation, signifies something that *adds to* precision in describing the nature of any object of which we are speaking. An adjective, in our language, is most commonly prefixed to the name of some thing, in order to mark some quality by which it is distinguished from other things belonging to the same class; thus, a *bad* man, a *good* man, a *fat* man, a *troublesome* man, &c., a *black* horse, a *white* horse, &c. Here the terms *man* and *horse* are the most general or abstract (ABSTRACTION) terms by which we can express the idea of man or horse: but, by prefixing to them such adjectives as *bad*, *good*, &c., we limit, in some degree, the class of which we are speaking. Thus, when we speak of a *white* man, we exclude the consideration of black men, or men of any other colour. In like manner, when we say an *English* man, we limit the signification still further; and in this way we may descend to a Cheshire man, a Chester man, until we come to individuals indicated by a common name, such as Thomson, Smith, &c. By the aid of other words prefixed, such as John, William, &c., we at last come to some certain individual. It appears, then, that in the expressions John Page, William Smith, &c., John and William may have the names of adjectives as well as the words *black*, *white*, &c. And this leads us to observe that frequently *nouns* or names of things can be used like adjectives; thus we can say, a *silver ring*, a *gold stick*, *salt water*, *sea water*. Many words in English are, in fact, used both as nouns and adjectives. In the expression 'John's book,' *John's* may be considered as an adjective for the reasons just given. Some grammarians have wished to introduce the term *adnoun* instead of *adjective*, but though the word *adjective* is not a very good name, *adnoun* is no better.

There are two ways in which an adjective can stand in a proposition: we can say 'the horse is bad,' or 'a bad horse.' In the first example, *horse* is called the 'subject,' *is* the 'copula,' or connecting link, and 'bad' is the 'predicate' or qualifying term. According to the true idiom of our language, an adjective can stand at the end of any simple proposition, as, he walks *slow*, he rides *quick*, he speaks *loud*. It is true that usage is now beginning to be opposed to this mode of expression, and the adverb in *-ly* is gaining ground; yet there are cases where it is not possible to use the termination in *-ly* without making the spoken language at least very stiff and formal. Some words are used both as adjectives and adverbs.

Many adjectives are simple *roots*, such as *good*, *bad*, *hot*, &c., while others are formed by adding an affix or suffix to a noun.

The following list of adjectives formed by affixes, or by adding a complete word, belong to the Saxon part of our language:—

glad-some	care-less	for-ward
play-ful	child-ish	god-like
weight-y	holl-ow	man-ly
wood-en	fork-ed	out-er

The following terminations are of Latin and Greek origin

act-ive	coher-ent	period-ical
passion-ate	attend-ant	station-ary
adamant-ine	habit-able	transit-ory
sulphur-ic	aud-ible	Belgi-an
angul-ar	luc-id	humor-ous
duc-tile	autumn-al	verb-ose

There are other terminations of less importance, such as *ether-eal*, *advent-itious*, &c., which agree with the examples already given, as to the *last* syllable, but differ in having an additional syllable or syllables between the first part of the word and the termination.

ADJUDICATION, in the law of Scotland, is a process by which real property and its accessories is transferred by law from the debtor to the creditor, from the heir to the devisee, or from the vendor who refuses or has failed to convey, to the vendee. The origin of this process is to be found in an ancient practice called Apprising, by which the debtor who refused to satisfy his creditor, either with money or land, might be compelled to part with so much of the land as was commensurate with the debt. It was the object of legislation so early as 1469, when feudal superiors or lords were compelled to give the proper investiture to those who acquired lands by such procedure, which was again amended by the Act 1672, c. 19. The debtor is now to make over to the creditor land to the value of his debt and one-fifth more, redeemable within five years; or the property in general against which the process is directed adjudged to the creditor, liable to be redeemed within ten years, on payment of the debt, interest, &c. The latter alternative is universally adopted. The lands do not pass into the absolute property of the adjudger at the end of the ten years, without judicial intervention, in what is called "an action of declarator of expiry of the legal," whereby the creditor has the right of redemption in the debtor declared to have expired and ceased altogether.

There are arrangements for preserving equality among adjudgers, and preventing active creditors from carrying off all the estate. (Acts 1661, c. 62; 1672, c. 19; 54 Geo. III. c. 137, ss. 9—11.) When there are many adjudications against an estate, and when the debtor does not come within the class of persons liable to mercantile bankruptcy, it is usual to sweep all the operations into one process, called a 'Judicial Ranking and Sale.' A factor is appointed, by whom, under judicial inspection, the property is realised and distributed. (Acts 1681, c. 17; 1695, c. 24; 54 Geo. III. c. 137, ss. 6, 7; Act. Sed., 22nd Nov., 1711; 17th Jan., 1756; 11th July, 1794.) Where sequestration has been awarded against a person liable to bankruptcy, the sequestration involves an adjudication of all the bankrupt's property from him, and vests it in the trustee (official assignee). (19 & 20 Vict. c. 79 20 & 21 Vict. c. 19.)

This form of action has long been in use for the completion of defective titles to landed property, and when so employed, it is called 'adjudication in implement;' as for instance when the heir declines to convey an estate left to a devisee in a will.

ADJUSTMENT, in marine insurance, is the ascertaining the exact amount of indemnity which the insured is entitled to under the policy, after all proper allowances and deductions have been made. The contract of insurance is an agreement to indemnify the insured against such losses as he may sustain by the occurrence of any of the events expressly stated or by implication of law contained in the policy. When a ship is lost, or any of those contingencies arise against which the insurance provides, the owner of the ship or of the goods insured, as the case may be, or his authorised agent, reports the circumstance to the insurers or underwriters. In London, this notice is given by an insertion in a book kept at Lloyd's Coffee-House in the subscription-rooms, where the greater part of marine insurances are effected.

Before any adjustment is made, the underwriters require to be informed of all particulars, that they may be satisfied the loss has occurred through circumstances against which the insurance was effected. In ordinary cases the task of ascertaining these facts, and of examining the correctness of the demand made by the assured, rests with the underwriter who first subscribed the policy. In complicated cases of partial or average losses, the papers are usually referred to some disinterested party (generally a professional referee), to calculate and adjust the per centage rate of loss. Where the ship is wholly lost, of course little difficulty occurs in this part of the inquiry; but in cases of partial losses, where the insured has not exercised his right of abandonment [ABANDONMENT], very minute and careful examination is often necessary. The quantum of damage being ascertained, the amount which each underwriter has made himself liable to by subscribing the policy is settled; and this being done, it is usual for one of the underwriters, or their agent, to indorse on the policy, "adjusted a partial loss on this policy of so much per cent." To this indorsement the signature of each underwriter is affixed, and this process is called the 'adjustment' of the loss.

After an adjustment has been made, it is not usual in mercantile practice for the underwriter to require further proof, but at once to pay the loss. The reason for which adjustments have been introduced into the business of maritime insurance is, that upon the underwriter signing an adjustment, time is given him by the assured to pay the money. In law, however, it seems to be as yet undecided how far the adjustment is conclusive and binding upon the underwriters. The better opinion is that the adjustment is merely *primâ facie* evidence against an insurer; so that where an adjustment has taken place, and the liability to pay the loss is disputed, while the adjustment, without further proof, will be sufficient to entitle the insured to recover in an action on the policy, the underwriter will not be debarred from showing facts which may have the effect of relieving him from liability. (Arnould on the *Law of Marine Insurance.*)

ADJUTAGE, or AJUTAGE, is a name given to a tube, generally not exceeding a few inches in length, which may be applied to a vessel or reservoir, in order to facilitate the discharge of a fluid from such vessel. [HYDRODYNAMICS.]

ADJUTANT. } [STAFF, MILITARY.]
ADJUTANT-GENERAL. }

ADMINISTRATION AND ADMINISTRATOR. An administrator is a person appointed to administer or distribute the goods of a person who has died without making a will. The right of appointment, which had for centuries been lodged in the ordinary or bishop of the diocese, has by a recent statute (20 & 21 Vict. c. 77) been transferred to the Queen's Court of Probate. In very early times, the king, in his character of *pater patriæ*, was supposed entitled in such a case to seize upon the goods, in order to apply them to the burial of the deceased, the payment of his debts, and the making of a provision for his family. This power of the crown was doubtless abused; for, by Magna Charta, "if a freeman shall die intestate, his chattels shall be distributed by the hands of his near relations and friends, under the inspection of the Church." This probably formed the foundation upon which the prelates afterwards built their right to administer by their own hands the goods of an intestate. At all events, the power of taking possession of the goods of an intestate was, at a later period, transferred from the crown to the bishops. The property was, in the first instance, placed in the custody of the bishop of the diocese in which the intestate died; and after the deduction of what were technically called *partes rationabiles* (two-thirds of the whole, which the law gave to the widow and children), the remaining third part vested in the bishop upon trust to distribute in charity to the poor, or in what were then termed "pious uses," for the benefit of the soul of the deceased. This trust was greatly abused by the prelates, who unscrupulously converted the whole residue of the property to the use of their order, without even paying the just debts of the deceased; to remedy which the statute of Westminster the Second was passed in the reign of Edward I., providing that the debts of the deceased should be paid by the ordinary in the same manner as if he had been an executor appointed by a will. The remainder, after payment of debts, continued applicable to the same uses as before. Farther to prevent abuse of the power still retained by the ordinary, and to take the administration entirely out of his hands, the statute 31 Edward III. c. 2, directed the ordinary, in case of intestacy, to depute "the nearest and most lawful friends" of the deceased to administer his goods; and these administrators are put upon the same footing with regard to suits and to accounting, as executors appointed by will.

This is the origin of administrators: they were merely the officers of the ordinary, appointed by him in pursuance of the statute, which selects the nearest and most lawful friend of the deceased; these words being interpreted to denote the nearest relation by blood who is not under any legal disability. The subsequent statute of 21 Henry VIII. c. 5, enlarged the power of the ecclesiastical judge, and permitted him to grant administration either to the widow or the next of kin, or to both of them. Where several persons were equally near of kin, he was empowered to select one at his discretion. If none of the kindred were willing to administer, a creditor was permitted to do so; and in the absence of any person entitled to demand letters of administration, the ordinary might appoint whomsoever he might think proper. The powers and discretion of the ordinary are now vested in the judge of the Court of Probate.

Administrators may be nominated even in a case where a will has been made, if by the will no executors are appointed, or if the persons named refuse, or are not legally qualified to act. In these cases the administrator only differs from an executor in the name of his office and mode of his appointment. In practice, when the executor *refuses*, administration is granted to the residuary legatee; that is, to the person to whom, by the will, the residue of the property, after payment of debts and legacies, is given.

In the case of a complete intestacy, it was formerly much doubted whether an administrator appointed under 31 Edward III. could be compelled to distribute the effects which remained in his hands after payment of debts; for though the administration had been transferred from the ordinary to him, he stood in the same position as the former had occupied, and was consequently not legally bound to administer. The spiritual courts endeavoured to enforce distribution by taking bonds from the administrator for that purpose, but these were declared void by the common law courts. The Statute of Distributions (22 & 23 Charles II. c. 10), which now regulates these matters, enacts that the surplus effects, after payment of debts, shall, after the expiration of one year from the death of the intestate, be distributed in the following manner: One-third to the widow, and the remainder in equal proportions to the children of the intestate, or, if dead, to their legal representatives—that is, their lineal descendants; or, if there be no children, or children's legal representatives, one moiety to the widow, and the other moiety to the next of kin, in equal degrees of relationship, or to their representatives: if no widow, the whole to the children or their representatives in equal portions: if neither widow nor children, the whole amongst the next of kin or their representatives.

By the same statute, it is directed that no child of the intestate (except it be his heir at law) on whom he settled in his lifetime any estate in lands or pecuniary portion, equal to the distributive share of the other children, shall have any part of the surplus to be administered; but if the estate given by way of advancement is not equivalent to the others' share, the child so advanced shall have enough to put him on an equality with his brothers and sisters. The 29 Charles II. c. 3, gives administration to the husbands of women dying intestate.

The Statute of Distributions expressly reserved the customs of the city of London, of the province of York, and of all other places having peculiar customs of distributing intestates' effects. These customs have been abolished by the statute 19 & 20 Vict. c. 94, and the distribution of the estates of intestates is thus rendered uniform throughout England. ('Blackstone's Comm.' Mr. Kerr's ed. vol. ii. p. 554.)

For further information see EXECUTORS, and PROBATE, COURT OF.

ADMIRAL, the title of the highest class of naval officers. Various fanciful etymologies of the word have been given; but the word is said to be merely a corruption of the Arabic *Amir* or *Emir*, a lord or chieftain. The *al* is the Arabic definite article *al* (the), without the noun to which it belongs. Eutychius, patriarch of Alexandria, writing in the 10th century, calls the Caliph Omar *Amirol Mumenim*, which he translates into Latin *Imperator Fidelium* (Commander of the Faithful). To form the word Admiral the first two terms of some title similar to this have been adopted, and the third has been dropped. From this it appears that the word ought properly to be written, or rather ought at first to have been written, Amiral, or Ammiral, as we find it in Milton's expression:

> "The mast
> Of some great Ammiral."

Milton, holding to this principle of orthography, wrote in Latin *Ammiralatûs Curia* (Court of Admiralty). The French say *Amiral*, and the Italians *Ammiraglio*. The *d* seems to have got into the English word from a notion that Admiral was an abridgement of *Admirable*. The Latin writers of the middle ages sometimes, apparently from this conceit, style the commander of a fleet *Admirabilis*, and also *Admiratus*; the Spaniards say *Admirante* or *Almirante*.

Under the Greek empire, the term *Emir* or *Amir* (Αμηρ) was used most commonly to designate the governor of a province or district, which was itself called Αμηραδιας. Gibbon states that the Emir of the fleet was the third in rank of the officers of state presiding over the navy; the first being entitled the *Great Duke*, and the second the *Great Drungaire*. ('Decline and Fall,' ch. liii.) The holy wars of the 12th and 13th centuries seem to have introduced the term Admiral into Europe. The Admiral of Sicily is reckoned among the great officers of state in that kingdom in the 12th century; and the Genoese had also their admiral very soon after this time. In France and England the title appears to have been unknown till the latter part of the 13th century: the year 1284 is commonly assigned as the date of the appointment of the first French Admiral; and the *Amiral de la Mer du Roy d'Angleterre* is first mentioned in records of the year 1297. The person to whom the title is given in this instance is named William de Leybourne. Yet at this time England, although she had an admiral, had, properly speaking, no fleet; the custom being for the king, when he engaged in a naval expedition, to press into his service the merchant-vessels from all ports of the kingdom, just as it is still the prerogative of the crown to seize the men serving on board such vessels. This circumstance is especially deserving of notice, as illustrating what an admiral originally was. The King of England's Admiral of the Sea was not necessarily the actual commander of the fleet; he was rather the great officer of state who presided generally over maritime affairs. Sometimes he was not a professional person at all; at other times he was one of the king's sons, or other near kinsman yet in his nonage, on whom the office was bestowed, as being one of great dignity and emolument; the duties were performed by persons who acted in his name. But these duties were usually not to command ships in battle, but merely to superintend and direct the naval strength of the kingdom, and to administer justice in all causes arising on the seas. The former of these duties is now executed by the department of government called the Admiralty, and the latter by the legal tribunal called the High Court of Admiralty.

Anciently, two or more admirals used often to be appointed to exercise their powers along different parts of the coast. Thus, in 1326, mention is made of Admiral of the King's Fleet, from the mouth of the Thames northward, and of another officer, with the same title, commanding from the mouth of the Thames westward. Besides these, there were also Admirals of the Cinque Ports. There are still a vice-admiral and a rear-admiral of the United Kingdom, which places are now sinecures, and are usually bestowed upon naval officers of high standing and eminent services. They are appointed by royal patent, and it is said would exercise the authority of the Lord High Admiral in case of his death, until a successor was appointed. There is also a vice-admiral of the coast of Yorkshire, a nominal office, usually given to a nobleman. It is the opinion of some writers that the first admiral of all England was appointed in the year 1387. Even the officer bearing this title, however, was not then the person possessing the highest maritime jurisdiction. Above him there was the King's Lieutenant on the Sea (*Locum tenens super mare*). Also, before the term Admiral was used at all, there was an officer designated the Custos Maris, or Guardian of the Sea.

From the year 1405 (the sixth of Henry IV.) there is an uninterrupted series of Lord High Admirals of England, the office being always held by an individual, till the 20th of November, 1632, when it was for the first time put in commission: all the great officers of state were the commissioners. During the Commonwealth, the affairs of the navy were managed by a Committee of Parliament, till Cromwell took the direction of them himself. On the Restoration, the king's brother, the Duke of York, was appointed Lord High Admiral; and he retained the place till the 22nd of May 1684, when Charles took it into his own hands. On the duke's accession to the throne, in the beginning of the following year, he declared himself Lord High Admiral. On the Revolution the office was again put in commission; and it continued to be held in this form till 1707, when Prince George of Denmark was appointed Lord High Admiral, with a council of four persons to assist him. On his death in November, 1708, the Earl of Pembroke was appointed his successor, with a similar council. The earl resigned the office in 1709, since which time, till now, it has always been in commission, with the exception of the period of about sixteen months (from May 1827, till September 1828), during which it was held by King William IV., then Duke of Clarence. The Commissioners, styled the Lords Commissioners of the Admiralty, were formerly seven, and are now six in number; and the first lord is always a member of the cabinet. It is the first lord, indeed, who principally exercises the powers of the office. The patent constituting the commission is issued by writ of privy seal, in the king's name, and after mentioning the names of the commissioners, it appoints them to be "our commissioners for executing the office of our High Admiral of our said United Kingdom of Great Britain and Ireland, and of the dominions, islands, and territories thereunto belonging, and of our High Admiral of Jamaica, Barbadoes, Saint Christopher, Nevis, Montserrat, Bermudas, and Antegoa, in America, and of Guiney, Binny, and Angola, in Africa, and of the islands and dominions thereof, and also of all and singular our other foreign plantations, dominions, islands, and territories whatsoever, and places thereunto belonging, during our pleasure; giving, and by these presents granting unto you, our said commissioners, or any two or more of you, during our pleasure, full power and authority to do, execute, exercise, and perform all and every act, matter, and thing which do belong or appertain to the office of our High Admiral," &c., as well in those things which concern the navy as in the things which concern "the right and jurisdiction" of the High Admiral.

Till the reign of Queen Anne the salary of the Lord High Admiral was only 300 marks; and the emoluments of the place, which were very large, arose chiefly from perquisites, or droits, as they were called, of various descriptions. Prince George of Denmark resigned all these droits into the hands of the crown, and received in their stead a salary of 7000*l.* a year. The salary of the First Lord is 4500*l.*, and his official residence is the Admiralty, Whitehall. The salary of the junior lords is 1000*l.*, and they have official residences; or, in case of the government not appropriating to them an official residence, a sum of 200*l.* is allowed instead.

The title of Admiral is also given in modern times to naval officers of the highest rank; of which we have in England three classes, namely, Admirals of the Red, of the White, and of the Blue. Admirals bear their flag at the main top-gallant-mast head; vice-admirals, at the fore top-gallant-mast head; and rear-admirals, at the mizen top-gallant-mast head. After the union with Scotland in 1707, the use of the red flag was discontinued, the union-jack being substituted for it; but it was resumed at the naval promotion which took place in 1805, after the battle of Trafalgar. There are also vice-admirals and rear-admirals of each flag, the former ranking with lieutenant-generals, and the latter with major-generals in the army. A full admiral ranks with a general, and an admiral who is actually the commander-in-chief of a fleet with a field-marshal. The title of Admiral of the Fleet is merely an honorary distinction. The sea-pay of the two admirals of the fleet, is 6*l.* per day; admirals, 5*l.* per day; vice-admirals, 4*l.* per day; and rear-admirals, 3*l.* per day. In addition to this pay, every commander-in-chief receives a further sum of 3*l.* per day while his flag shall be flying within the limits of his station.

There is no officer with the title of admiral in the navy of the United States of America (one has just (1859) had this rank and title conferred for his life). The highest office is that of commodore, which is given to captains commanding on stations.

ADMIRALTY COURTS, in Law, are courts having jurisdiction over maritime causes, whether of a civil or criminal nature. In England, the Court of Admiralty is held before the Lord High Admiral or his deputy, who is the judge of the court: when there was a Lord High Admiral, the judge of the Admiralty usually held his place by patent from him; but when the office of admiral is executed by commissioners, he holds his place by commission under the great seal.

The Court of Admiralty is usually called the Instance Court, to distinguish it from the Prize Court. The commissions to the judges are perfectly distinct, but are usually given to the same person. The Prize Court is only constituted n time of war. Neither is a Court of Record.

The Instance Court is usually held at Doctors'-Commons. The law it administers is composed of such parts of the civil law as treat of maritime affairs, together with the laws of Oleron and other maritime laws, and such alterations or amendments as have been introduced by Acts of Parliament, or usage which has received the sanction of legal decision. Its practice has been improved and its jurisdiction extended by the stat. 3 & 4 Vict. c. 65. An appeal from its judgments lies to the Queen in Council.

In criminal matters the Court of Admiralty has, partly by common law, partly by a variety of statutes, sole cognisance of piracy and all other indictable offences committed either upon the sea or on the coasts, beyond the limits of any English county (13 & 14 Vict. cc. 26, 27.) Its proceedings were according to the civil and maritime laws, until the statute 28 Henry VIII. c. 15 enacted that its proceedings should be according to the common law. The statute 7 & 8 Geo. IV. c. 28, next directed all offences tried in the Court of Admiralty to be punished in the same manner as if committed on land. A similar provision was made by 9 Geo. IV. c. 31. Ultimately, the Central Criminal Court in London was, by 4 & 5 Wm. IV. c. 36, empowered to determine offences committed within the jurisdiction of the Admiralty. By 7 & 8 Vict. c. 2, authority was given to the judges of assize and commissioners of oyer and terminer to try all offences within the jurisdiction of the Admiralty; so that, practically, the ordinary criminal courts now determine all prosecutions for offences within the Admiralty jurisdiction.

The civil jurisdiction of the Instance Court extends generally to marine contracts, that is, to such contracts as are made upon the seas,—as where the vessel is pledged during the voyage for necessary repairs; and to some few others, which, though entered into on land, are executed entirely upon the sea,—such as agreements for mariners' wages. If part of a cause of action arise on the seas and part on the land, the jurisdiction of the Admiralty Court is excluded. In contracts made abroad, they exercise in most cases a concurrent jurisdiction with the Courts of Common Law. The Admiralty Court has no cognizance of contracts under seal, except where, from the nature of the subject matter, it has exclusive jurisdiction; as in the case of an hypothecation bond, under which a ship is given in pledge for necessaries furnished to the master and mariners. This security binds the vessel on which the money is advanced. It imposes no personal contract on the borrower, and so does not fall within the cognizance of the common law. The Instance Court likewise regulates many other points of maritime right, such as disputes between part-owners of vessels, and questions relating to wreck and salvage. (9 & 10 Vict. c. 99.) It has also power to inquire into certain injuries committed on the high seas, such as collision, and in such cases to assess the damages to be paid to the party injured.

The Vice-Admiralty Courts established in our colonies are regulated by the 2 Wm. IV c. 51. They have a jurisdiction as to seamen's wages, pilotage, collisions, &c. (9 & 10 Vict. c. 99.) There is an appeal to the Queen in Council, that is, to the Judicial Committee of the Privy Council. (3 & 4 Wm. IV. c. 41.)

Offences committed on the sea may be dealt with in the colonies, as if the offence had been committed on waters within the local jurisdiction of the courts of the colony (12 & 13 Vict. c. 96. s. 1); and questions relating to the attack and capture of pirates may now also be determined in the Vice-Admiralty Courts abroad. (13 & 14 Vict. cc. 26, 27.)

The Prize Court is the only tribunal for deciding what is lawful prize, and for adjudicating upon all matters relating to prize. By 'prize' is understood every acquisition made *jure belli* (by the law of war), which is either itself of a maritime character, or is made, whether at sea or by land, by a naval force. All acquisitions by right of war belong, by the law of war, to the sovereign power in the state, but are usually, by the law of each particular state (as in England by several acts of Parliament), distributed in certain proportions among the persons who took or assisted in taking them. But agreeably to the law of nations, the property in the thing captured is not considered to be taken from the original owners until, by the sentence of a properly authorised court, it has been condemned as lawful prize. We have, as it should appear, no court authorised to adjudicate on property captured by land forces, or *booty*, as it is commonly termed by writers on the law of nations; but, when occasion requires (as when property to an immense amount was captured by the British army in the conquest of the Deccan), commissioners are specially appointed for the purpose. The 3 & 4 Vict. c. 65 enacts that the High Court of Admiralty shall have jurisdiction to decide all matters and questions concerning booty of war, that is, property captured by land-forces, when referred to it by the Privy Council. But property captured by the naval force forms the peculiar province of the Prize Court of the Admiralty. "The end of a Prize Court," says Lord Mansfield, "is to suspend the property till condemnation; to punish every sort of misbehaviour in the captors; to restore instantly, if upon the most summary examination there does not appear sufficient ground to condemn; finally, if the goods really are prize, against everybody, giving everybody a fair opportunity of being heard." (Douglas's Reports, p. 572, &c.) The Prize Court has also jurisdiction in matters of capture in port or on land, when the capture has been effected by a naval force, or a mixed naval and military force.

From prize causes, whether in the Court of Admiralty in England, or in the Vice-Admiralty Courts, an appeal lies directly to certain commissioners of appeal in prize causes, who are appointed by the crown under the great seal.

Vessels taken under the treaties for the suppression of the slave-trade are adjudicated by a mixed commission, composed of English and foreign commissioners.

In 1840 an act was passed (3 & 4 Vict. c. 66) to make provision for the judge, registrar, and marshal of the Court of Admiralty. It fixes the salary of the judge at 4000*l.*, with a retiring pension of 2000*l.* after fifteen years' service, or on becoming permanently disabled from performing his duties. The salary of the registrar is 1400*l.*, without fees. The registrar is appointed by the judge, and must be a proctor of not less than ten years' standing. One of the duties of the registrar is to attend the hearing of appeals before the Privy Council, instead of the registrars of the Court of Chancery, on whom this duty devolved under 3 & 4 Wm. IV. c. 41. On the next vacancy in the office of judge of the Admiralty, or judge of the Probate Court, these offices are to be united (20 & 21 Vict. c. 77).

All sovereign states which are engaged in maritime war, establish Admiralty Courts, for the trial of prizes taken by virtue of the commissions which they have granted. In determining prize cases, the Admiralty Courts proceed on certain general principles which are recognised among civilised nations. Thus the commission which empowers the Prize Court to determine cases of prize, requires it to "proceed upon all and all manner of captures, seizures, prizes, and reprisals of ships and goods, which are or shall be taken, and to hear and determine according to the course of the Admiralty and the law of nations."

The Court of Admiralty for Scotland was abolished by 1 Wm. IV. c. 69. The cases in their nature civil, formerly brought before this court, are now prosecuted in the Court of Session, or in that of the sheriff, in the same way as ordinary causes. The Court of Justiciary is the tribunal for the decision of the more important maritime offences. The inferior jurisdictions not dependent on the High Court of Admiralty were not abolished by the above act. (Burton's 'Manual of the Law of Scotland.') There is an Admiralty Court in Ireland, but a prize commissioner has never been sent to it. By s. 108 in the Corporations Reform Act (5 & 6 Wm. IV. c. 76) all chartered Admiralty jurisdictions were abolished; but that of the Cinque Ports, attached to the office of Lord Warden, was expressly reserved. (Stokes 'On the Colonies,' p. 357.)

(Dr. Browne's *View of the Civil Law*, and the *Law of the Admiralty*; Comyns's *Digest*, tit. 'Admiralty;' Blackst. *Comm.* Mr. Kerr's ed. iii. p. 76; iv. p. 314.)

ADMIRALTY, DROITS OF. [DROITS OF THE ADMIRALTY.]

ADMISSIONS, in a suit in equity, are those facts necessary to support the case of a plaintiff, or of a defendant, the necessity of proving which is removed by the opposite party admitting them.

Admissions are either, 1, Upon the record; or, 2, By agreement between the parties.

1. Admissions upon the record, again, are either Actual or Constructive.

Actual Admissions are those which appear in the bill or in the answer. A plaintiff cannot read any part of his bill in evidence, unless it is corroborated by the answer.

Of *Constructive Admissions*, the most ordinary instance is when a plea has been put in either to the whole or part of a bill; in which case the bill, or that part of it pleaded to, and not controverted by the plea, is admitted to be true.

A plaintiff may rest satisfied with the admission, and need not prove the fact not controverted by evidence.

Again, the statement of facts contained in a plaintiff's bill is in equity (but not at law) constructive admission as against him of the facts as stated, when the allegation is positive, as of his own acts, or of facts within his knowledge, but not when they are stated hypothetically, for the purpose of raising an answer to an anticipated defence, with a protest against their being considered as admitted; and the bill may be read as evidence of the facts so positively averred, not only in the suit in which the bill is filed, but in another suit.

There is a difference between actual and constructive admissions, in the manner in which they are presented to the court. The former are read to establish the case of the party reading them, in the same manner as the other evidence in the cause; the latter are stated to the court when the pleadings are opened, for the purpose of showing what are the matters in issue between the parties, and what are the facts which by the form of the pleadings they are precluded from disputing.

In an answer, not only the simple admission of a fact, but the statement of a defendant that "he believes," or has been "informed, and believes" such a fact to be true, is sufficient, unless the statement be accompanied by some clause to prevent its being considered as an admission. The answer of an infant, being in fact the answer of his guardian, cannot be used against the infant. But the rule is different with respect to the answer of an idiot or lunatic put in by his committee, or that of a person of weak intellect put in by his guardian. In these cases, admissions in the answers are evidence against them. The joint answer of a husband and wife may be read against them in matters relating to the wife's personal estate; but neither the joint answer, nor the separate answer of the husband, with relation to her inheritance. The answer of one defendant is not evidence against a co-defendant, unless where a defendant makes it so by referring to a statement in the answer of his co-defendant.

The courts of equity permit the plaintiff to read any portion of the answer which he thinks will support his case, provided that, in reading the admission of a fact, he reads at the same time any admissions or qualifications with which it is accompanied, and the whole of the passage in which the admission is contained. The rule is different in courts of law, in which, if an answer in equity is offered in evidence against a party, he has a right to insist upon the whole being read.

2. Admissions by agreement between the parties are those which the parties or their attorneys or solicitors agree upon between themselves, for the sake of saving expense or preventing delay. They are usually made in writing, and signed by the parties or their solicitors, but not necessarily so. Agreements for admissions will not be sanctioned by the court if they violate any known principles of law. Thus, there can be no agreement to waive an objection to an instrument for want of a stamp.

(Daniell's *Chancery Practice*, by Headlam, 3rd. ed. vol. i. p. 669, et seq.)

ADMITTANCE. [COPYHOLD.]

ADOPTION (from *adoptare*) means taking by choice. By the Roman law, if a person had no children of his own, he might appoint any other person's, whether related to him or not, to be his children *by adoption*. In order to understand the ordinary mode of adoption and its legal effects, it must be remembered that the relation of father and son was very analogous to that of master and slave, both in the rights and duties attached to it, and in the manner in which it was dissolved. Hence, under the old law (that is prior to Justinian's time) if a person wished to adopt the son of another, the natural father sold the boy to him by a regular sale before a magistrate. In order that he might be emancipated from his father's authority, so as never to fall under it again, it was requisite that this sale should be repeated *three* several times. In strict accordance with the direction of the old law, which is thus laid down in the XII Tables, "Si pater filium *ter* venumduit filius a patre liber esto." [EMANCIPATION.] The father thus lost all his paternal rights over the child, who by this triple sale as regarded the purchaser, was put *in mancipio*, and did not become his filius familias until a fictitious suit or feigned recovery took place (called *cessio in jure*) when the child became, to all intents and purposes, a member of the family of his purchaser or adopter. If the person to be adopted was *sui juris*, that is, his own master, the mode of proceeding was by a bill (analogous to our private acts of parliament) proposed to the people in the comitia curiata. (Aul. Gell. 'Noct. Att.' v. 19, Cicero 'Pro Domo,' 29.) This was called *Arrogation*, from *rogare*, to propose a bill. In either case the adopted child became subject to the authority of his new father; passed into his family, name, and sacred rites, and succeeded to his property. Clodius, the enemy of Cicero, passed by this ceremony from the patrician to the plebeian rank, in order to qualify him to be tribune. (Cic. 'Pro Domo,' 12, 13; Suet. 'Tiber. Nero,' 2.)

The history of Rome abounds with instances of adoption. One of the sons of Paulus Æmilius, the conqueror of Macedonia, was adopted by the son of Scipio Africanus the Elder, and having thus passed from the *Æmilian* into the *Cornelian gens*, acquired the name of Publius Cornelius Scipio Æmilianus, to point out the family of his birth and adoption; when he destroyed Carthage in the third Punic War, he received, like his adoptive grandfather, the appellation of Africanus, and is usually spoken of as Scipio Africanus the Younger.

Under the emperors the mode of adoption became the subject of reform; and that which for many ages could be effected only by a circuitous course of arbitrary forms, founded upon legal fictions, was allowed to be done by a short and simple process before a magistrate.

There was also a custom of adopting children by will, which was not only in vogue in the days of the Republic, but was even known in very ancient times, when it was not unusual for the Romans to adopt (*adsci scere*) their *heredes sui* or children into their nomina. (Cic. 'de Offic.' iii. 18; Corn. Nep. 'Offic.' c. 5; Suet. 'Jul.' 83; Tacit. 'Annal.' 3, 30; and Ovid, 'Metamorph.' xv. 818.) Julius Cæsar thus adopted his great nephew Octavius, who was thenceforth called Caius Julius Cæsar Octavianus, but is generally known under the appellation of Augustus, which he afterwards assumed. (Heineccius, 'Antiquitates Romanæ,' lib. i. tit. xi.) In like manner, several emperors adopted their successors; for instance, Augustus adopted his grandson Agrippa, and his step-son Tiberius. (Tacit. 'Ann.' i. 3; Suet. 'Aug.' 65.) So Tiberius, by the order of Augustus, adopted his nephew Germanicus, who died in the lifetime of Tiberius; and on the death of Tiberius, Caligula, the son of Germanicus, became emperor. At a subsequent period, Claudius went so far as to adopt his step-son Domitius, afterwards the Emperor Nero, to the exclusion of his own son Britannicus. Tacitus remarks, that Nero was the first stranger in blood ever adopted into the Claudian family. (Tacit. 'Annal.' xii. 25.) At various periods of Roman history so great inconvenience was experienced in consequence of the general disinclination to marriage, that rewards were held out for its encouragement, and penalties imposed upon celibacy. Immunities from state burdens were given to those who possessed many children; and to obtain these, the adoption of children became a great abuse. Aulus Gellius, in his short notice of the legal forms and effects of adoption, cites an oration of P. Scipio the Censor, who complains of the custom prevalent in his time, that "an adoptive son should entitle his adoptive father to privileges in the state." (Aul. Gel. 'Noct. Att.' v. 19.) Under Julius Cæsar, after the wars, laws for the encouragement of population were proposed, but not carried into effect; but under Augustus the Julian law was proposed, A.U.C. 736, which contained heavy penalties upon celibacy, and proportionate rewards for the possession of children. This law was so unpopular, that, Suetonius says, it could not be executed. (Sueton. 'Aug.' 34.) Afterwards however a law passed, called from the consuls who introduced it, 'Lex Papia Poppæa,' by which, among other privileges given to those who possessed children, it was declared that, of candidates for prætorships and other offices, those should have the preference who had the greatest number of children. This occasioned what Tacitus calls, in speaking of the time of Nero, a "pestilent abuse, which was practised by childless men, who, whenever the election of magistrates was at hand, provided themselves with sons by fraudulent adoptions; and afterwards, when in common with real fathers they had obtained prætorships, instantly released themselves from their adopted sons." The genuine fathers petitioned for relief, which produced a decree, that in the pursuit of any public employment whatever, no feigned adoptions should be of any avail, nor in taking estate by will. (See Tacit. 'Annal.' xv. 19.)

The eleventh title of the first book of Justinian's 'Institutes' relates to adoption. There were then two kinds of adoption, one called *arrogatio*, when by a rescript of the emperor (*principali rescripto*), which had, it will be recollected, replaced the authority of the comitia, a person adopts another who is *sui juris;* the other, when by authority of the magistrate (*imperio magistratûs*), he who is under the control of his parent (*alieni juris*) is made over to another person, and adopted by him either as his son, his grandson, or a relation in any inferior degree. Females might be adopted in the same manner. But when a man gave his child to be adopted by a stranger, the parental authority did not pass from the natural to the adoptive father; the only effect was, that the child succeeded to the inheritance of the latter if he died intestate. It was only when the adopter was the child's paternal or maternal grandfather, or otherwise *in loco parentis*, so that the right of nature concurred with that of adoption, that the new connection became the same as an original one. The adopter must in all cases have been at least eighteen years older than the person he adopted. Women, according to the laws of Justinian, were not entitled to adopt; but after having lost children by death, they might, by the indulgence of the emperor, be permitted to receive those of others in their place. A slave, on being named a son by his master before a magistrate, became free, but acquired no filial right.

The intimate connection between the *Patria potestas* and *adoptio* must never be lost sight of; because that explains the importance of the subject now under discussion, and the reason why its rules were so carefully and accurately developed; for adoption really was the act by which an individual was received into the position of a son or grandson, not so much from motives of affection on the adopter's part as from those of policy, enabling the adopter to acquire a *patria potestas*, and thus conferring by a fictitious parentage civil and agnate rights. Hence we may see the force of the expression, "Filios familias non solum natura verum et adoptiones faciunt" (D. 1, 7, 1); and "Adoptio non jus sanguinis, sed jus agnationis affert" (D. 1, 7, 23).

The German system of adoption is derived from the Roman law, though it cannot be said, according to the proper meaning of the word, to have been in force before the 15th or 16th century. Any adoption, in order to be strictly and properly a legal process, must take place before a court, or be confirmed by the proper authorities. The adopted son retains his family name, and prefixes or adds to it that of his adoptive father; but in case a nobleman adopts a commoner, the son does not succeed to the rank, unless it is confirmed by the sovereign. The more modern German institutes still keep to the principles of the Roman system of adoption, though the whole is modified so as to be more in harmony with German usages. The Prussian law does away with all distinction between *adoption* and *arrogation;* and allows the adopted son who is of age to manage his own property. The Austrian law does the same. Both also agree in requiring the age of the adoptive father to be fifty at least. The Prussian law, with respect to the adopted son, merely requires him to be younger than the father; while the Austrian code requires him to be eighteen years younger than the adoptive father. (Ersch and Gruber's 'Encyclopädie,' art. 'Adoption.')

The French law is to be found in the eighth title of the first book of the 'Code Civil.' Adoption is permitted to persons of either sex, provided they are above the age of fifty, having neither children nor other legitimate descendants, and being at least fifteen years older than the individual adopted. It can only be exercised in favour of one who has been an object of the adopter's constant care for at least six years during minority, or of one who has saved the life of the adopter in battle, from fire, or from drowning. In the latter cases, the only restriction respecting the age of the parties is, that the adopter shall be older than the adopted, and shall have attained his majority, or his twenty-first year, but he or she must also be without children or lawful descendants, and if married must obtain the consent of the conjunct. In every case the party adopted must be of the age ef twenty-one. The form is for the two parties to present themselves before the local judge (*juge de paix*) for the place where the adopter resides, and in his presence to execute an act of mutual consent; after which the transaction, before being accounted valid, must be approved of by the next superior court, the *tribunal of first instance*, within whose jurisdiction the domicile of the adopter is. The adopted takes the name of the adopter in addition to his own; and no marriage can take place between the adopter and either the adopted or his descendants, or between two adopted children of the same individual, or between the adopted and any child who may be afterwards born to the adopter, or between the one party and the wife of the other. The adopted acquires no right of succession to the property of any relatives of the adopter; but as to the property of the adopter he has the same rights as a child born in wedlock, and that, even although there should be other children of the latter description born after his adoption. It has been decided in the French courts that aliens cannot be adopted.

Adoption is still practised among the Turks, and other eastern nations. It is common for a rich Turk, who has no children of his own, to adopt as his heir the child of persons even of the poorest class. The bargain is ratified before the Cadi, and their mutual consent recorded; after which the child cannot be disinherited by his adoptive father. D'Herbelot states, that, according to the law of Mohammed, a person becomes the adopted son of another by undergoing the ceremony of passing through his shirt; whence the expression, to draw another through one's shirt, signifies to adopt him for a son. In India the same thing is said to be frequently done by the two parties merely exchanging girdles. In the Code of Gentoo Laws published by Mr. Halhed, the 9th section of the 21st chapter is entitled 'Of Adoption.' The law permits a child under five years of age to be given up for adoption by its father for a payment of gold or rice, if he have other sons, on the parties going before a magistrate and having a *jugg*, or sacrifice, performed. A woman, however, it is added, may not adopt a child without having her husband's consent; and there is even some doubt if she may with that. "He," concludes the law, "who has no son, or grandson, or grandson's son, or brother's son, shall (may?) adopt a son; and while he has one adopted son, he shall not adopt a second."

There is no *Adoption* in the English or Scottish system of law: though we find mention of it in Bracton l. 2 c. 29 n. 4, 5 (but see Coke, 2 'Inst.' 97). The courts have, however, recognised it as a matter of feeling and affection, in the case of seduction allowing an adopter to stand *in loco parentis*, and a compensation to be given, not only for mere loss of services, but also for the aggravated injury done to the object of affection. (Edmonson *v.* Machell, 2 T. R. 4; Irwin *v.* Dearman, 11 East. 23.)

ADULT-SCHOOLS are establishments for instructing in reading and other branches of knowledge, those persons who had not been educated in their youth. They were designed to meet the wishes of people who were no longer contented to remain uninstructed, and who did not think that the privation of an early education should necessarily entail upon them the evil of perpetual ignorance.

The first school avowedly established for the purpose of instructing adults, was formed in 1811, through the exertions of the Rev. T. Charles, a clergyman in Merionethshire. Some grown-up persons had previously attended his parish Sunday-school, but they showed a disinclination to learn with children, and this circumstance led to the adoption of more extended views for their benefit. Considerable success both in the number and progress of the pupils, and their improved conduct and character, caused the establishment of other adult-schools throughout Wales.

About the same time, and without any concert or connection with the schools in Wales, a school was established at Bristol through the instrumentality of W. Smith. This person, "who collected the learners, engaged the teachers, and opened the two first schools in England for instructing adults exclusively, in borrowed rooms, and with borrowed books" (Pole's 'History and Origin of Adult Schools'), was the door-keeper to a dissenting chapel. He devoted three out of eighteen shillings, his weekly earnings, to defray the expense of giving to his brethren the means of studying the Scriptures, and of obtaining knowledge from other sources. A short time after these first efforts were made, a society was formed for the furtherance of his benevolent views. In the first report of this society, dated April, 1813, it was stated, that 222 men and 231 women were already receiving education. Adult-schools were soon afterwards established in different parts of the kingdom, at Uxbridge, Norwich, Ipswich, Sheffield, Salisbury, Plymouth, and other places.

The extension, however, and the great improvements made in the education of the young, seems to have interfered very materially with such schools as are mentioned above. Few, except under particular circumstances or the patronage of some benevolent individuals, now exist. What may now be called adult-schools are of a far higher character, and have been instituted to enable young men who have received the rudiments of an early education to continue their progress, either in particular departments or in general knowledge, in the hours which they can spare from their business occupations. Of such a nature are the classes in various Mechanics' Institutes, the Crosby Hall evening classes for young men, at the Working Men's Colleges in Sheffield, at Salford, at Wolverhampton, and in Great Ormond Street, London; by the lectures to working-men given at the Geological Museum in Jermyn-street, the Edinburgh Apprentice Schools, and various other places of a similar character. These are very numerous, and productive no doubt of great advantage, not only to individuals but to society; there is, however, no record by which we can ascertain the numbers. The evening classes at King's College, London, are of a somewhat higher character, as giving the privilege of an university examination, and they are numerously attended. A great portion of those attending are young men, but not a few are men of middle age.

But though progress has thus far been made, there is yet a lamentable deficiency of education among the labouring classes. In 1856, there were 29 per cent. of the men, and 40 per cent. of the women, who could not write their names on their marriage. Still, this is an improvement: in 1841, the per centage was 33 of the men, and 49 of the women. As the improvements in education are of course among the more youthful, it is to be expected that even the later numbers will now rapidly decrease. The number of persons who could not write their names in the marriage register of 1856, indicates the state of education some twelve or fifteen years earlier.

ADULTERATION (from the Latin *Adulteratio*) is the use of ingredients, in the production of any article, which are cheaper and not so good, or which are not considered so desirable by the consumer, as other or genuine ingredients for which they are substituted. The sense of the Latin word is the same. (Pliny, 'Hist. Nat.' xxi. 6.) The law does not consider adulteration generally as an offence, but relies apparently on an evil of this nature being corrected by the discrimination and good sense of the public. The selling of unwholesome provisions, as meat or fish, is generally punishable under local acts. The 51 Hen. III. st. 6 prohibited the sale of unwholesome flesh, or flesh bought of a Jew, under pain of fine and imprisonment. In Paris, malpractices connected with the adulteration of food are investigated by the Conseil de Salubrité, acting under the authority of the prefect of police. In this country, strict regulations have been resorted to in order to prevent adulteration.

Tobacco-manufacturers are liable to a penalty of 200*l.* for having in their possession sugar, molasses, honey, roots of malt, ground or unground roasted grain, ground or unground chicory, lime, ochre, or other earths, sea-weed, ground or powdered wood, moss or weeds, or any leaves, or any herbs or any substance, syrup, liquid or preparation, capable of being used as a substitute for, or to increase the weight of, tobacco or snuff (5 & 6 Vict. c. 93, § 5). Any person engaged in the preparation of articles to imitate tobacco or snuff, or who shall sell such articles to any tobacco-manufacturer, is liable to a penalty of 200*l.* (§ 8). The penalty for adulterating tobacco or snuff is 300*l.* (§ 1); and for having such tobacco or snuff in possession, 200*l.* (§ 3). The t ade in tobacco as to licences, &c., is regulated by the above-mentioned statute, and the 3 & 4 Vict. c. 18.

The ingredients used in the adulteration of beer are enumerated in the list of articles which brewers or dealers in beer are prohibited from having in their possession under a penalty of 200*l.* (56 Geo. III. c. 58, § 2). These articles are—molasses, honey, liquorice, vitriol, quassia, cocculus Indicus, grains of Paradise, Guinea pepper, and opium. Preparations from these articles are also prohibited. They are used as substitutes for hops, or to give a colour to the liquor in imitation of that which it would receive from the use of genuine ingredients; § 3 of the act imposes a penalty of 500*l.* upon any chemist, or other person, who shall sell the articles mentioned to any brewer or dealer in beer. The penalties against dealers are extended to beer-retailers under the 11 Geo. IV. and 1 Wm. IV. c. 64, and 4 & 5 Wm. IV. c. 85, which contain special provisions against adulteration applicable to this class of dealers. These provisions are continued and extended by the 3 & 4 Vict. c. 61. The 5 & 6 Vict. c. 30, makes regulations for the preparation and use of roasted malt in brewing, and the 10 Vict. c. 5, 13 & 14 Vict. c. 67, and 17 & 18 Vict. c. 30 allow sugar to be used, subject to regulations of the Commissioners of Inland Revenue.

Selling 'corrupted wine' is punishable under the 51 Hen. III. st. 6. By the 12 Car. II. c. 25, the adulterating of wine is punishable with a fine of 100*l.* on the merchant, 40*l.* on the vintner; and additional regulations are made by 1 Wm. & M. st. 1. c. 39.

Tea, another important article of revenue, is protected from adulteration by several statutes. The act 11 Geo. I. c. 30, § 5, renders a teadeal r liable to a penalty of 100*l.* who shall counterfeit, adulterate, or manufacture any tea, or mix with tea any leaves other than leaves of tea (§ 5). Under 4 Geo. IV. c. 14, tea-dealers who dye, fabricate, or manufacture any sloe-leaves, liquorice-leaves, or the leaves of tea that have been used, or other leaves in imitation of tea; or use terra japonica, sugar, molasses, clay, logwood, or other ingredients, to colour or dye such leaves; or sell or have in their possession such adulterated tea, are liable to a penalty of 10*l.* for every pound of such adulterated tea found in their possession (§ 11). The 17 Geo. III. c. 29, also prohibits adulteration of tea (§ 1).

The adulteration of coffee and cocoa is punished under 43 Geo. III. c. 129. Any person who manufactures, has in his possession, or sells burnt, scorched, or roasted peas, beans, grains, or other grain or vegetable substance prepared as substitutes for coffee or cocoa, is liable to a penalty of 100*l.* (§ 5). The object of § 9 of 11 Geo. IV. c. 30, is similar. Chicory is extensively used in the adulteration of coffee. This root came into use on the Continent in consequence of Bonaparte's decrees excluding colonial produce, and coffee with which a fourth or a fifth part of chicory has been mixed is by some persons preferred as a beverage to coffee alone. The Excise has for some time permitted the mixture of chicory with coffee. Besides the quantity imported, chicory is also grown in England.

The manufacturer, possessor, or seller of adulterated pepper is liable to a penalty of 100*l.* (59 Geo. III. c. 53, § 22).

The act 9 Geo. IV. c. 44, § 4, extends the various acts relative to the excise on tea, coffee, cocoa, pepper, &c., to the United Kingdom.

All penalties prosecuted by the Excise are by § 2 of the same statute to be recovered according to 8 Geo. IV. c. 53 (see 12 & 13 Vict. c. 1); but if they are incurred within the limits of the chief office of Inland Revenue in London, the information may, by the 15 & 16 Vict. c. 61, be determined by justices of the peace.

As regards the important article of bread, the act 6 & 7 Wm. IV. c. 37 (which repealed the several acts then in force relating to bread sold beyond the city and liberties of London, and ten miles of the Royal Exchange), was also intended to prevent the adulteration of meal, flour, and bread beyond these limits. No other ingredient is to be used in making bread for sale except flour or meal of wheat, barley, rye, oats, buckwheat, Indian corn, peas, beans, rice, or potatoes, mixed with common salt, pure water, eggs, milk, barm, leaven, potato or other yeast, in such proportions as the bakers think fit (§ 2). Adulterating bread, by mixing other ingredients, is punishable by a fine of not less than 5*l.* nor above 10*l.*, or imprisonment not exceeding six months: and the names of the offenders are to be published in a local newsp per (§ 8). Adulterating corn, meal, or flour, or selling flour of one sort of corn as flour of another sort, subjects the offender to a penalty not exceeding 20*l.* and not less than 5*l.* (§ 9). The premises of bakers may be searched, and if ingredients for adulterating meal or flour be found, the penalty for the first offence is 10*l.* and not less than 40*s.*; for the second offence 5*l.*, and for every subsequent offence, 10*l.*; and the names of offenders are to be published in the newspapers (§ 12). There are penalties for obstructing search (§ 13). Any miller, mealman, or baker acting as a justice under this statute, incurs a penalty of 100*l.* (§ 15).

The above act did not apply to Ireland, where the baking trade was regulated by an act (2 Wm. IV. c. 31), the first clause of which, relating to the ingredients to be used, was similar to the English act just quoted. In 1838 another act was passed (1 Vict. c. 28), which repealed all former acts relating to the sale of bread in Ireland. The preamble recited that the act 6 and 7 Wm. IV. c. 37, had been found beneficial in Great Britain; and the clauses respecting adulteration are similar to the English act.

The several acts for regulating the making of bread within ten miles of the Royal Exchange (which district is excluded from the operation of 6 & 7 Wm. IV.) were consolidated by the act 3 Geo. IV. c. cvi. Under this act any baker who uses alum, or any other unwholesome ingredient, is liable to the penalties mentioned in § 12 of 6 & 7 Wm. IV. c. 37. Any ingredient or mixture found within the house, mill, stall, shop, &c. of any miller, mealman, or baker, and which shall appear to have been placed there for the purpose of adulteration, renders him liable to similar penalties.

Other articles besides those which have been mentioned are adulterated to a great extent, and there is scarcely an article, from arrowroot to guano, which escapes. The interference of Government with the practice of adulteration, except in the case of bread and drugs [APOTHECARIES' COMPANY], has had no other object than the improvement of the revenue.

Adulteration and the deceitful making up of commodities attracted the attention of the legislature in the 16th century, and several acts were passed for restraining offences of this nature.

ADULTERY, the offence of incontinence between two married persons, or between two persons, one of whom is married. In the latter case it is called *single*, in the former, *double* adultery. (Cowel, 4.)

This crime was punished by the Jewish law with death; but the adultery which by the Mosaic law constituted a capital crime, was not every violation of chastity of which a married person might be guilty, but only the sexual connection of a wife with any other man than her husband. This distinction was part of the Jewish marriage-law, by which the husband and wife had not an equal right to restrain each other from infidelity. The former might marry other wives, or take concubines and slaves to his bed, without giving his first wife a right to complain of any infringement of her matrimonial rights. The punishment, however, of incontinence in a married woman with a stranger, was, by the Levitical law, death by stoning, both in the case of the stranger and the adulteress. (Levit. xx. 10, and Michaelis, 'Mosaisches Recht.') By the Athenian law, the husband might kill the adulterer, if he detected him in the act of dishonouring him. (Lysias's 'Oration on the Death of Eratosthenes.')

The Roman corresponds with the Hebrew law. Civilians define adultery to be the violation of another man's bed (*violatio tori alieni*); so that the infidelity of a husband could not constitute the offence. The more ancient laws of Rome, extremely severe against the offence of the wife, were silent as to that of the husband. By an old law, an adulteress was to be slain by her husband and his relations (*adulterii convictam vir et cognati uti volent necanto*). At a later period, by the Lex Julia (Dig., l. 48, t. 5; Paulus, Sentent. Recept. ii. 26), passed in the time of Augustus, about 17 B.C., adultery in the wife was punishable by banishment; she forfeited half her dowry and a third part of her property. The adulterer forfeited half his goods to the public use, and was also banished. But although by the Julian law adultery was not punishable with death by legal sentence, the father, natural or adoptive, of the adulteress was in some cases permitted to kill both her and her paramour; and in some cases the husband had the same power. A constitution of Constantine made adultery a capital offence in the male. (Cod. ix. t. 30.) Justinian (Novel. 134, c. 10) confirmed the law of Constantine, and added confinement in a convent as the punishment of the adulteress, after she had been whipped.

By the canon law, now more or less interwoven into the municipal laws of most Christian countries, adultery is defined to be the violation of conjugal fidelity. Consequently, incontinency in the wife or the husband stand on the same foundation. Hence arises the distinction between single and double adultery, already alluded to, which are punishable in various ways in most of the countries of modern Europe, but in none of them, at the present day, is either of these offences capital, and in few of them, in fact, is the public offence punished at all.

There are faint traces of the punishment of adultery as a crime in the early periods of the history of English law. Lord Coke says that in ancient times it was within the jurisdiction of the sheriff's tourns and court-leet, and was punished by fine and imprisonment (3 Inst. 306); but at the present day adultery is not the subject of criminal prosecution. Till quite recently it was only cognisable as an offence in the Ecclesiastical Courts; but instances of criminal prosecutions there are extremely rare. If instituted and followed out to the conviction of the parties, the infliction of a slight fine or penance "for the benefit of the offender's soul" (*in salutem animæ*), as it is termed, would be the only result. In 1604 (2 James I.) a bill was brought into Parliament "for better repressing the detestable crime of adultery," but it was dropped. (Parl. History, vol. v. p. 88.) During the Commonwealth, adultery in either sex was made a capital felony (Scobel's 'Acts,' part ii. p. 121); at the Restoration this law was discontinued.

Adultery however, till the erection of the Court for Divorce [DIVORCE], came under the cognisance of the temporal courts in England as a private injury to the husband. A man might maintain an action against the seducer of his wife, in which he might recover damages as a compensation for the loss of her services and affection in consequence of the adultery. This was felt to be a scandal and a reproach to the law of England, and the action of *crim. con.* was accordingly abolished (20 & 21 Vict. c. 85), "but by an unpardonable omission in legislation, this is accomplished in words only, whilst in effect—indeed in words equally plain—a similar right of action is given to the husband through the instrumentality of the Court, but to be tried by a jury. A man may now recover damages for his wife's infidelity without seeking for a divorce, but may continue to live with her upon the damages recovered from the paramour, which may be settled upon her and upon the children. Even when a divorce is obtained, the damages may be settled upon the children of the marriage; and the father may live with his children whilst they are maintained and educated with the price of their mother's dishonour." (Lord St. Leonard's, 'Handy Book,' p. 77.)

In Scotland, the Act 1563, c. 74, punished the notorious and habitual adulterer, man or woman, with death. The latest instance of sentence of death in Scotland for adultery is perhaps that of Margaret Thomson, May 28, 1677. All the statutes on the subject have, according to the peculiar practice of Scotland, expired by long desuetude. In the 17th and the commencement of the 18th century, the church courts were very active in requiring the civil magistrate to adjudicate in this offence; but this means of punishment was rendered nugatory by the 10th Anne c. 7, § 10 (the Toleration Act), which prohibited civil magistrates from giving effect to ecclesiastical censures. Of late years the doctrine has been admitted by Scottish lawyers, that the seduction of a wife is good ground for an action of damages; but such prosecutions are wholly unknown in practice. Adultery alone is in Scotland a good ground on which to obtain a divorce. (Hume, 'On Crimes,' i. 452–458; Stair's 'Institutes,' b. i. tit. 4, s. 7; Erskine's 'Institutes,' b. i. tit. 6, s. 43.)

The French law (Code Pénal) makes it excusable homicide if the husband kill the wife and the adulterer in the act of adultery in his own house. The punishment of a woman convicted of adultery is imprisonment for not less than three months, and not exceeding two years; but the prosecution can only be instituted at the suit of the husband; and the sentence may be abated on his consenting to take back the wife. The paramour of a wife convicted of adultery is liable to imprisonment for not less than three months, or for a period not exceeding two years; and to a penalty of not less than 100 francs, or not exceeding 2000 francs.

In the state of New York, the Court of Chancery is empowered to pronounce a complete divorce in the case of adultery, and in no other cases, upon the complaint either of the husband or the wife. The process is by bill filed by the complaining party. If a divorce is pronounced, the defendant is disabled from marrying during the lifetime of the other party.

ADVENT, literally, the approach or coming, is the space of four weeks preceding Christmas, appointed in the English and other Christian Churches to be kept holy in celebration of the approach of our Saviour's nativity or manifestation. Anciently, the season of Advent consisted of six weeks, and, commencing therefore about Martinmas, used to be called the *Sancti Martini Quadragesima*, or the Forty Days' Lent of St. Martin. It is still of this duration in the Greek Church. The first Sunday in Advent, commonly called Advent Sunday, is now the Sunday, whether before or after, which falls nearest to St. Andrew's day (the 30th of November).

ADVENTURE, BILL OF, a writing signed by a merchant, stating that the property of goods shipped in his name belongs to another, the adventure or chance of which the person so named is to stand, with a covenant from the merchant to account to him for the produce. In commerce an 'adventure' is a speculation in goods sent abroad under the care of a supercargo, to dispose of to the best advantage to his employers.

ADVERB, in grammar, the name given to a class of words employed with verbs, adjectives, &c., for the purpose of qualifying their meaning, just as the adjective itself is attached to substantives. In the English language a very large majority of adverbs are distinguished by the termination *ly*, which in the Anglo-Saxon has the fuller form *lice*, and in German, *lich*. Our own language possesses the same suffix in the form *like*, as *godlike, gentlemanlike*. These, however, and many other words in *ly*, are adjectives, as *manly, ugly*; and it is difficult to draw the line between these two classes, many words, especially in the older writers, being used indifferently for both [ADJECTIVE]. The word to which the adverbial suffix *ly* is added is generally an adjective, but occasionally the adjective has become obsolete in the present form of our language, and must be sought in the Anglo-Saxon. Thus *early* is derived from the Anglo-Saxon *aer*, which indeed still appears in the now poetical forms *ere*, and the superlative *erst*. But though the termination *ly* is derived from the Teutonic portion of our language, it has been applied most freely to adjectives of Latin origin, as *publicly, privately*; and with these may be classed the adverbs from adjectives in *ble*, as *horribly, agreeably*, in which the liquid belongs at once to the adjective and the suffix. An important class of adverbs are formed by prefixing the old Saxon preposition *an* or *on* to nouns, in which a careless pronunciation afterwards left nothing but the vowel *a*, as *on fote*, now *a-foot*. Lastly, we have an interesting though ludicrous formation depending upon alliteration, *helter-skelter, hurry-skurry, pell-mell, higgledy-piggledy*, &c. The same love of alliteration, which is said to have formed an important element in Anglo-Saxon versification, has also given rise to some adjectives and substantives, as *hum-drum, slip-slop, tip-top, tittle-tattle, hurly-burly*.

ADVERTISEMENT, from the French *avertissement*, which means an announcement or notice of any kind, is the general name of those announcements published in newspapers, magazines, and other works appearing periodically, whatever be their peculiar character. The first English advertisement which can be found, is in the 'Impartial Intelligencer,' for 1649, and relates to stolen horses. In the few papers published from the time of the Restoration to the imposition of the Stamp Duty, in 1712, the price of a short advertisement appears seldom to have exceeded a shilling, and to have been sometimes as low as sixpence. [Nichols's 'Literary Anecdotes,' vol. iv.] The practice of advertising soon began to increase, till the tax was imposed upon advertisements in 1712. This might check, but could not stop, the increase of a practice found to be so advantageous in all commercial transactions as well as in many other affairs. Advertisements continued to multiply, not only in number, but in the organs through which they were diffused, and soon began to be not only a considerable means of support to the medium in which they appeared, especially to the newspapers, but a source of revenue to the country. The tax on each advertisement, whatever its length, was formerly 3*s*. 6*d*.; and in the year 1832, the total number of newspaper advertisements in the United Kingdom was 921,943, viz., 787,649 in England, 108,914 in Scotland, and 125,380 in Ireland—the duty amounting to 172,570*l*. But the tax was felt to be an unfair and an oppressive one, and the number and the amount continued nearly stationary for several years. In 1833, therefore, the act of 3 and 4 Wm. IV. cap. 23, passed June 28, reduced the duty to 1*s*. 6*d*. on each advertisement in England, and to 1*s*. in Ireland, the loss to the revenue being estimated by the Chancellor of the Exchequer at 70,000*l*. Advertising again took a start, and in 1841 the total number of advertisements in the United Kingdom amounted to 1,778,957, and the duty to 128,318*l*. The income thus derived to the newspapers was largely expended in improving them; their size was universally enlarged, in some cases doubled; and as the number of newspapers did not materially increase, the circulation also doubled. The 'Times,' which had been for many years a large advertising paper, contained 1474 superficial square inches of print on each side, and in 1836 it commenced issuing supplementary sheets, frequently of equal size, and at other times of half that size. In 1845 during nine weeks from Sept. 6 to Nov. 1, it was stated in an interesting article on the curiosities of advertising, in Vol. xcvii. of the 'Quarterly Review,' that the receipts of the 'Times' for advertisements were 44,056*l*. On Aug. 4, 1853, by the 16 &

17 Vict. cap. 63, the duties on advertisements were remitted altogether. In the year ending Jan. 5, 1851, there had appeared in English and Scotch newspapers 2,016,422 advertisements, and 236,128 in Irish newspapers, producing together a revenue from the tax of 326,075*l.* 11*s.* In June 1855 the compulsory stamp on newspapers was also remitted, the stamp being used solely for postage purposes. This has given a fresh impulse to advertising, by occasioning the establishment of extremely cheap newspapers, many of which contain a printed superficies of about 1300 square inches on each side, and are sold for a penny. To give an example of the extent of advertising, we may state that the double number of the 'Times' for January 5, 1859,—being an average number—contains 2305 advertisements. In nearly every case advertisements supply the fund out of which newspapers are supported, as the price, even of the higher-priced papers, is insufficient to pay the cost of the paper, the printing, the editing, the collecting of news—a most important and heavy item, and the management. The prices charged for advertisements vary according to the amount of circulation of the paper, and in some degree according to the character of the advertisement, short advertisements, not exceeding three lines, of persons wanting situations, being charged in some cases as low as 1*s.* Now the duty is off, there are no returns made for fiscal purposes, and it has become nearly impossible to ascertain the exact number of advertisements published annually, but it may be confidently stated that they have at least doubled; that is, they now amount to upwards of four millions in the United Kingdom. In the United States of America, where no duty is imposed, they are estimated to amount to ten millions. It was certainly wise to remove all obstructions, in our complicated state of society, to the means of informing the public of new improvements, of inventions, of the wants of some, and of the resources for supplying them possessed by others; in short, of bringing together, from the most distant parts of the empire, the information calculated to promote both the individual and public advantage.

ADVICE, in its legal signification, has reference only to bills of exchange. The propriety of inserting the words "as per advice," depends on the question whether or not the person on whom the bill is drawn, is to expect further directions from the drawer. Bills are sometimes made payable "as per advice;" at other times "without further advice;" and generally without either of these words. In the former case the drawer may not, in the latter he may, pay before he has received advice.

Advice, in commercial language, means information given by one merchant or banker to another by letter, in which the party to whom it is addressed is informed of the bills or drafts which have been drawn upon him, with the particulars of date, &c., to whom payable, &c., and where.

ADVOCATE, from the Latin *advocatus*. Among the Romans, an advocate was a person skilled in the laws. Advocates in Rome owed their origin to the institution of *patron* and *client*, by which every head of a patrician house had a number of dependents, who looked to him as a protector, and in return owed him certain obligations. It was the principal, and one of the most ordinary duties of the patron, to assist the client in his suits by advice and advocacy, so that the relation was gradually contracted to this extent.

Though the word 'advocate' is now used to express a person who manages a case in court, this is not the meaning of the Roman word. The Advocatus was any person who gave another his aid in any business, as a witness, for instance, or otherwise. It was used in a restrictive sense to signify one who gave his aid in a cause. The Advocatus of the republican period was not the modern Advocate. He who appeared for plaintiff or defendant was termed Orátor or Patronus. Ulpian, however, who wrote in the beginning of the third century, A.D., defines Advocatus to be one who assisted another in the conduct of a suit (Dig. b. 50, tit. 13), and under the Empire we find Advocatus used as synonymous with Orátor. Hadrian established an Advocatus Fisci, whose functions were to look after the Fiscus, or imperial revenue.

In the early period of the Roman republic, the Advocate was held in high estimation. It was then the practice to plead gratuitously; those who aspired to honours in the state taking this course to render themselves distinguished. As the simplicity of ancient manners disappeared, the services of advocates became venal. At first, presents were given, as acknowledgments of gratitude for services rendered; but these gradually assumed the character of debts, and at length became a kind of stipend periodically payable by clients to those of the patrician order who devoted themselves to pleading. In this form it became an abuse; so much so, that the Tribune Cincius, about 200 years before Christ, procured a law, called from him Lex Cincia, prohibiting advocates from taking money or gifts from their clients. In the time of Augustus this prohibition had become obsolete; for the Cincian law was revived, and advocates commanded to plead gratuitously, under a penalty of four times the amount of the fee they received. Notwithstanding these restrictions, the tendency was always to recur to a pecuniary remuneration; for in the time of Claudius we find a law restraining advocates from taking exorbitant fees, and fixing as a maximum the sum of 10,000 sesterces, equivalent to about 80*l.* sterling, for each cause pleaded. (Tacit. Ann. xi. 5.) Some years afterwards, Pliny mentions a decree passed in his time, that all litigants in courts of justice, previously to the hearing of their causes, should take an oath that they had neither given, promised, nor secured, any reward of money to any person employed as their advocate.

In later periods, as the Roman law diffused itself over Europe, these restrictions upon the remuneration of advocates entirely disappeared in practice. In form, however, the fee was merely an honorary consideration (*quiddam honorarium*), and was generally, but not necessarily, *prenumerated*, or paid to the advocate before the cause was pleaded. It was a rule that, if once paid, the fee could never be recovered, even though the advocate was prevented by death or accident from pleading the cause; and where an advocate was retained by his client at an annual salary (which was lawful and usual), the whole yearly payment was due from the moment of the retainer, though the advocate died before the expiration of the year. (Heineccii, 'Elementa Juris Civilis.' p. 132.) Manifest traces of this practice are still to be found in all countries into which the civil or Roman law has been introduced, and are also discernible in the rules respecting fees to counsel at the present day in England.

In countries where the Roman law prevails, pleaders in courts of justice are still called advocates; their character, duties, and liabilities being extremely various under different governments. [ADVOCATES, FACULTY OF; BARRISTER.]

ADVOCATE, LORD, the name given to the principal counsel for the crown, and the public prosecutor in Scotland. He is asisted by a solicitor-general and some junior counsel, generally four in number, who are termed Advocates-Depute. He appears as prosecutor when any person is tried for an offence, and in all actions where the Crown is interested. The inferior courts have their respective public prosecutors, called Procurators Fiscal, who act under his instructions. This officer generally makes the preliminary inquiries as to crimes committed in his district; and after transmitting the papers to the office of the Lord Advocate, he, or one of his assistants, either directs the case to be prosecuted before the superior court, that is, the Court of Justiciary, or leaves it to the conduct of the Procurator Fiscal in the inferior court. When a private party prosecutes, which is of very rare occurrence, it is part of the formal practice for him to obtain the concurrence of the Lord Advocate. The Lord Advocate sat in the Scottish Parliament in virtue of his office as one of the officers of state. Like any other party to a cause, he never acts as a magistrate in his own person, but obtains such warrants as he may require from the Court of Justiciary. He and his assistants are always members of the ministerial party, and it is their practice to resign when there is a change of ministers. The Lord Advocate is virtually Secretary of State for Scotland. His duties in this capacity are multifarious, and the extent of his power not clearly defined.

ADVOCATES, FACULTY OF. The Faculty of Advocates in Edinburgh constitute the Bar of Scotland. It consists of about 400 members, but only a small portion are practising lawyers. It is usual for country gentlemen to acquire the title of advocate, in preference to taking a degree at the Scottish universities. The members may plead before any court in Scotland where the intervention of counsel is not prohibited by statute, in the House of Lords, and in parliamentary committees. Their claim to act as counsel is generally admitted in the colonial courts; and in those colonies where the civil law is in use, such as the Cape of Good Hope and the Mauritius, it is usual for those colonists who wish to hold rank as barristers to become members of the Faculty of Advocates. A candidate, who must at the outset either possess a degree at one of the Universities, or pass an easy preliminary examination, is next examined in Justinian's 'Institutes,' and required to translate passages from the 'Pandect.' After the lapse of a year he is examined in the municipal law of Scotland, and he then prints a thesis or essay on some title of the 'Pandect' assigned to him by the Faculty, the conclusions of which he must defend in a public meeting of the Faculty held to impugn them, after the method formerly followed in the universities. The thesis and impugnation are however mere forms. He is then admitted by ballot, which has likewise become a mere form, and on taking the oaths, is formally admitted to the privileges of the bar by the Court of Session. The expense of becoming a member of the Faculty, including stamp duty, subscription to the widows' fund, the subscription to the library, &c., amounts to about 380*l.* The Faculty choose a dean or chairman annually, but the office is generally held until the dean is promoted to the bench, a step which nearly always follows his election by the Faculty. The Lord Advocate, the Dean of Faculty, and the Solicitor-General, are the only persons who have precedence at the Scottish bar, independent of seniority. The Lord Advocate and Solicitor-General alone wear silk gowns and sit within the bar.

ADVOCATES' LIBRARY. The idea of establishing a library, for the use of the Faculty of Advocates in Scotland, seems first to have been entertained a few years before the Revolution. The author and active promoter of the plan was Sir George Mackenzie of Rosehaugh; but the precise date when Sir George's scheme was first approved and adopted by the faculty cannot be fixed. Mr. Alexander Brown, who was librarian to the Faculty of Advocates in 1772, says in the preface to 'Ruddiman's Catalogue,' which he edited, "The plan of forming a public library appears to have been adopted by the Faculty of Advocates about the year 1680."

At first, the Advocates' Library had no fixed fund, but subsisted and increased by means of donations, not from advocates only, but also from other individuals, and from such sums as the faculty, from time to time, placed at the disposal of the curators. Thus then it happened that, although the Advocates' Library, strictly speaking, belonged to the Faculty of Advocates as an exclusive body, it still was early considered as a public library, and was open to the public. This characteristic has rendered the institution very popular, and at the same time promoted its increase. In the year 1700 the greater part of the collection was consumed by fire. During the first nine years after its restoration the library must have increased considerably, since, in the eighth year of Queen Anne's reign, it obtained the privilege of receiving a copy of every new book which, by chapter 19 of the Acts of Parliament of that year, was conferred on it, with eight other libraries. Of these, five were Scotch libraries; and the disproportionate privilege may have originated in the desire of the legislature to grant some benefit to Scotland at the time of the Union. Shortly after the Union with Ireland, the same privilege was granted to two Irish libraries. This privilege has now ceased.

In Great Britain there are probably only two libraries, namely, the British Museum and the Bodleian, that out-number it. As might be expected, the collection of law books is very large, but far more complete in ancient than in modern works. Many important modern works of foreign jurisprudence are still wanting. The historical collection is exceedingly valuable, containing almost every work of importance that has been published in England, France, Italy, Spain, Portugal, Denmark, and Sweden. The collection of Greek and Roman classics is choice and extensive; the same may be said of that of modern poetry and *belles lettres*; there is also a very considerable divinity collection, and one of voyages and travels. Science has, however, been much neglected. There is a collection of MSS., by no means a large one; several of them are said to be important and available for Scottish history. They are, however, chiefly of local interest. In the year 1825, about 100 vols. of Icelandic MSS. were purchased from Professor Magnuson of Copenhagen. In the following year, Mr. Erskine, late of Bombay, made a donation to the library of a few valuable Persian and Sanscrit MSS. There are also a few MSS. of Latin classics, but of no great importance. There is a beautiful MS. of the Hebrew Bible, in two large folio volumes: the Pentateuch has, besides the Original, also the Chaldaic paraphrase.

The building which contains the Advocates' Library is not only confined, but dark and inconvenient, being distributed in several rooms, for the most part vaults or cellars below the old parliament-house, in which the Court of Session is now held. Some of these rooms are completely dark, and lighted by lamps; others have only borrowed light; and only three are properly lighted.

The Advocates' Library is governed by five curators, of whom one goes out of office by rotation every year, and one is chosen in his stead from among the body of the Faculty of Advocates. Under the curators there are, a keeper of the library, an assistant keeper, and two or three assistants. When the funds of the Faculty had somewhat increased, by raising the fees of entrants, the Faculty during a considerable period set apart 100*l.* from the fees of each entrant, and placed the amount at the disposal of the curators. The average of entrants each year has been stated to be seventeen, but this number is considerably above the average for many years past; and thus the annual income of the library at the period here alluded to, along with some additional fees, amounted to 1780*l.* In the year 1728, this system was altered, and the treasurer of the Faculty was ordered to pay 600*l.* annually out of the Faculty's income to the curators for the use of the library. This system still continues.

As to *ease of access*, there is no public institution in Great Britain, and very few in Europe, managed with greater liberality than the Advocates' Library; but we ought in candour to admit, that this is a somewhat equivocal compliment. It is however surprising that, although it has become almost a sort of bazaar, or a common lounging-place for a number of idle people, the library has suffered very little in consequence. Any stranger arriving in Edinburgh is admitted without introduction; but some introduction is required for habitually resorting to and reading in the library. Even borrowing of books is subject to very slight restriction. Each advocate enjoys the privilege of borrowing twenty volumes at a time; if he wishes to favour an individual who is not a member of the Faculty of Advocates with the loan of a book, he has only to sign the initials of his name in the journal or receipt-book, as a security. As there commonly are about two hundred advocates residing in Edinburgh, and as they are almost without exception remarkably liberal in lending books, it is in that city by no means difficult to obtain a free use of a very extensive library.

While the Court of Session sits, the Advocates' Library opens at nine o'clock in the morning, and shuts at four o'clock, p.m.; during vacation it is open from ten till four.

ADVOCATION, in the Law of Scotland, is the process by which a judgment in an inferior court is brought under the review of the Court of Session. In giving judgment, the court begins formally by advocating the cause.

ADVOWSON. The right of presenting a fit person to the bishop to be by him instituted to a certain benefice within his diocese which has become vacant. The person enjoying this right is called the patron, and the right is termed an advowson (*advocatio*), because the patron is bound to advocate or protect the rights of the Church, and of the incumbent whom he has presented.

This patronage might be liable to be misused by the intrusion of improper persons into the Church, so the law has provided a check, by giving to the bishop a power of rejecting the individual presented, for just cause. The ground of rejection is however not purely discretionary, but is examinable at the instance, either of the clergyman presented, or of the patron, by process in the ecclesiastical and temporal courts. [DUPLEX QUERELA; QUARE IMPEDIT.]

According to the best authorities, the appointment of the religious instructors within any diocese formerly belonged to the bishop: but when the lord of a manor, or landowner, erected a church, and set apart land or tithe for an endowment, it was the practice to give to the founder and his heirs the right of nominating a person in holy orders to be the minister as often as a vacancy should occur, the right of judging of the spiritual and canonical qualification of the nominee being reserved to the bishop. (Du Cange, 'Gloss.' tits. 'Advocatus,' 'Patronus.')

This seems to be the most satisfactory account of the origin of advowsons and benefices, and it corresponds with many historical records still extant, of which examples may be seen in Selden's 'History of Tithes.' It also serves to explain some circumstances of frequent occurrence in the division of parishes, which might otherwise appear anomalous or unaccountable. Thus the existence of detached portions of parishes, and of extra-parochial precincts, and the variable extent and capricious boundaries of parishes in general, would seem to indicate that they owe their origin rather to accidental and private dotation, than to any regular scheme for the ecclesiastical subdivision of the country. It is observable, that the boundaries of a parish either coincide with, or have a manifest relation to, manorial limits, and numerous instances are to be seen in different parts of England, in which the parochial place of worship is closely contiguous to the ancient mansion of its founder and patron, sometimes within the immediate inclosure of his demesne. As an illustration of the respect inculcated to the patron, we find also that the canons of the Church permitted him alone to occupy a seat within the chancel or choir, at a time when that part of the building was partitioned off from the nave, and reserved for the exclusive use of the clergy. (Kennett's 'Paroch. Antiq.' Glossary, tit. 'Patronus.')

An advowson which has been immemorially annexed to a manor, is called an *advowson appendant*, and is transmissible by any conveyance which is sufficient to pass the property in the manor itself. It may however be detached from the manor, and is then termed an *advowson in gross*, after which it can never be re-annexed, so as to become appendant again.

An advowson is regarded by law in the double light of a temporal property, and a spiritual trust. In the former view, it is a subject of transfer by sale, by will, or otherwise, and is available to creditors in satisfaction of the debts of the patron. It may be aliened for ever, for life, or for a term of years; or the owner may grant one, two, or any number of successive rights of presentation on future vacancies, subject always to certain restrictions imposed by the law, for the prevention of corrupt and simoniacal transactions.

On the other hand, the spiritual trust is guarded and enforced by very jealous provisions. The appointment of a duly qualified incumbent is secured, as far as the law can secure it, by requiring the sanction of the bishop. And in order to guard against the danger of a corrupt presentation, the immediate right to present is absolutely inalienable, if a vacancy has actually occurred. On a similar principle, a purchase of it during the mortal sickness of the incumbent is equally prohibited. [SIMONY.]

When the patron exercises his patronage, three persons are immediately concerned: the patron, the clergyman presented, or *clerk*, and the bishop in whose diocese the living is situate, or *ordinary*. The presentation is usually a writing addressed to the bishop, alleging that the party presenting is the patron of a church which has become vacant, and requesting the bishop to admit, institute, and induct a certain individual into that church, with all its rights and appurtenances. A period of time, limited to twenty-eight days, is allowed to the bishop for examining the candidate, at the expiration of which he is admitted and instituted to the benefice by formal words of institution read to him by the bishop, from an instrument to which the episcopal seal is appended. A mandate is then issued to the archdeacon or other officer to *induct*, that is, to put the new incumbent into the actual possession of the church and its appurtenant rights; and then, and not before, his title as legal *parson* becomes complete.

It sometimes happens, that two of the three characters of patron, clerk, and ordinary are united in one person. Thus the bishop may himself be the patron; in which case presentation being superfluous, institution alone is necessary. The bishop is then technically said to *collate* to the benefice, and the advowson is said to be *collative*.

So the clerk may be patron, in which case he may pray to be admitted by the bishop; or he may transfer to another the right of presentation, *pro hâc vice*, before the vacancy occurs, and then be presented.

The patronage and the parsonage are sometimes united in *appropriations*. Where the advowson, together with the church, its revenues and appurtenances, were in former times conveyed to some ecclesiastical body, they became both patrons and perpetual incumbents of the living, the immediate duties being devolved on a *vicar*, or a stipendiary *curate*.

There are advowsons, the patrons of which have power to appoint an incumbent without any resort to the bishop. These are called *donative*, because the patron exercises a direct and unqualified privilege of *giving* his church to a clerk selected by himself. The only check upon the incumbent in such cases, is the power of the patron to visit, and even to deprive him, when the occasion demands it; and the right in the bishop to proceed against him in the spiritual court for any ecclesiastical misdemeanour. Donatives are said to have their origin in the king, who had authority himself to found any church or chapel exempt from the episcopal jurisdiction, and might also, by special licence, enable a subject to do the same.

Sometimes the *nomination* is distinct from the right to present: thus, the owner of an advowson may grant to another the right to nominate a clergyman, whom the grantor and his heirs shall be thereupon bound to present. Here the person to whom the nomination is given, is substantially the patron, and the person who presents merely the instrument of his will. Where an advowson is mortgaged, the mortgagee is bound to present the person nominated by the mortgagor.

This species of property is coupled with a trust, in the faithful performance of which the public are deeply interested. If, therefore, upon the vacancy of a living, no successor, or an insufficient one, shall be presented, it is put under *sequestration* by the bishop, who must provide for the spiritual wants of the parish by a temporary appointment, the profits of the benefice being secured after deducting expenses, until another incumbent shall be inducted. If a vacancy of six months occurs by the default of the patron, the right to present *lapses* to the bishop himself; on default by him, to the archbishop, and from him to the king as paramount patron; six calendar months being allowed to pass in each case before the right is forfeited. A donative advowson, however, is excepted from this rule; for there the right never lapses by reason of a continued vacancy; the patron is only compellable to fill it up by the censures of the ecclesiastical court.

When the incumbent of a living is promoted to a bishopric, it is thereby vacated, and the king, in virtue of his prerogative, has a right to present to it in lieu of the patron. This claim on the part of the crown appears to have grown up since the Reformation, and was the subject of complaint and discussion down to as late a period as the reign of William and Mary. It is difficult to reconcile it to principle, although it has been urged by way of apology, that the patron has no ground to complain, because the king might, if he pleased, enable the bishop to retain the benefice, by the grant of a *commendam*; so that the patron sustains no other injury than what may result from the substitution of one life for another. It is certain that, by successive promotions, the crown may deprive the patron of his right for an indefinite time, and an instance actually occurred wherein the patron of the metropolitan parish of St Andrew was prevented by several such exertions of the royal prerogative, from presenting to his own living more than once in 100 years. ('Shower's Reports,' vol. i. p. 468.) So that, as was truly observed by the counsel in that case, the safest course that could be adopted by an unconscientious patron, with a view to retain in his own hands the future enjoyment of his right, would be to present a clergyman whose qualities are not likely to recommend him to higher preferment.

If a man marries a female patron, and a vacancy happens, he may present in the name of himself and wife.

Joint tenants and tenants in common of an advowson must agree in presenting the same person; and the bishop is not bound to admit on the separate presentation of either. Co-heiresses may also join in presenting a clergyman; and if they cannot agree in their choice, then they shall present in turn, and the eldest shall have the first turn.

When the patron dies during a vacancy, the right to present devolves to his executors. Where the patron happens to be the incumbent, his heir, and not his executor, is entitled to present.

When the patron is a lunatic, the lord chancellor presents; and he usually exercises his right in favour of some member of the lunatic's family, where it can with propriety be done.

An infant of the tenderest age may present to a living in his patronage, and his hand may be guided in signing the requisite instrument. In such a case the guardian who dictates the choice or directs the pen, is the real patron.

As to presentations to livings by the crown, see CHANCELLOR.

(Burn's *Ecclesiastical Law*, tits. 'Advowson,' 'Benefice,' 'Donative;' Selden's *History of Tithes*; Gibson's *Codex*, vol. ii.; Blackstone's *Commentaries*, Mr. Kerr's ed. vol. ii. p. 18.)

ADVOWSONS, VALUE OF. The following plain rules for estimating the value of advowsons, may be of use. The bargains which are usually made with respect to advowsons are, either for the advowson itself, that is, the right of presentation for ever, or for the right of presenting the next incumbent, that is, the next presentation. In both these cases there may be circumstances peculiar to the living itself, which fall under no general rule, but which must be considered and allowed for in valuing the advowson as a property. For example, a curate may be necessary; the parsonage-house may be in a state which will entail expenses on the next incumbent; and so on. Again, the property itself is of a nature more likely to be altered in value by the act of the legislature than the fee-simple of an estate. The following rules, therefore, give the *very highest value* of the advowson, and any purchaser should think twice before he gives as much as is found by them:—

To find the value of the perpetual advowson of a living producing 1000*l*. a year, the present incumbent being forty-five years of age, and money making four per cent., we must first find how many years' purchase the incumbent's life is worth, and here we should recommend the use of the government, or Carlisle tables [ANNUITIES], in preference to any other. Taking the latter, we find the annuity on a life of forty-five at four per cent., to be worth fourteen and one-tenth years' purchase; but at four per cent. any sum to be continued annually for ever is worth twenty-five years' purchase. The difference is ten and nine-tenths years' purchase, or for 1000*l*. a year, 10,900*l*, which is the value of the advowson.

In finding the value of the next presentation only, other things remaining the same, the seller will presume that the buyer means to make the best of his bargain by putting in the youngest life that the laws will allow, that is, one aged twenty-four. The value of an annuity on such a life at four per cent. according to the Carlisle tables, is seventeen and eight-tenths years' purchase. And as we are giving the highest possible value of the advowson, omitting no circumstance which can increase it, we will suppose the next incumbent to come into a year's profits of the living immediately on his taking possession. The present value of the next presentation is the value of an annuity for 17·8 years, beginning from the present year. The rule is this: Take four per cent. of the value of the incumbent's life, or 14 1 × ·04, which gives ·564; subtract this from 1, which gives ·436; divide by 1 increased by the rate per cent., or 1·04, which gives ·419; add one year's purchase to the presumed value of the next incumbent's life (17·8), which gives 18·8; multiply this by the last result, ·419, which gives 18·8 × ·419, or 7·88 nearly—the number of years' purchase which the next presentation is now worth—which, if the living be 1000*l*. a year, is 7880*l*.

We have thus given the very highest value: we will now state some of the circumstances which reduce it. If a curate must be kept, the yearly expense must be deducted from the income of the living. Again, expenses at entry, first fruits, &c., may be expected, one case with another, to swallow up the first year's income; accordingly, at least the year's purchase added in the above rule may be left out. But even when these deductions are made, there is *another curate* who has not been mentioned; the incumbent himself, whose mere salary for the work done must be put at the value for which a curate could be found to do it. A person who buys a living on which a curate must be kept, and deducts only for *one* curate, pays the salary of the rector or vicar out of his own pocket. By deduction of all the salaries (the incumbent's included), and expenses of entry, the lowest value is found. What it may be worth the while of any particular buyer to give, must depend upon a variety of circumstances which no actuary can value.

For all necessary tables, we may refer to Jones on Annuities.

A'DYTUM, ἄδυτον, a Greek term signifying *a place that may not be entered*, and applied to the innermost and secret chamber of a temple.

In the ancient Egyptian temple, the adytum is placed at the end of a series of propylæa, porticoes, and vestibules, and surrounded by galleries and chambers which afforded every facility for concealing the mysteries of the interior. In the temples of the Greeks there was sometimes an adytum, but nothing has been found corresponding to the adytum of the Egyptian temples, unless it be the chamber which, in the Parthenon at Athens, has been called the treasury. The temples of the Romans, also, are without obvious adyta, though the exhumation of Pompeii has discovered to us, in the temple of Isis there, a small chamber behind and under the altar and statue of the goddess, with means of secret access, from which probably the oracular responses were delivered.

The 'most holy place,' or the Sanctum Sanctorum, the holy of holies, was the adytum of the temple of Solomon at Jerusalem.

ÆDI'LES, from *ædes*, a building; the name given to certain magistrates in ancient Rome. They were four in number, two entitled *curule* ædiles, and two *plebeian*. It is difficult to mark the limit between the duties of these magistrates. The former however must have been originally connected with the patrician order, and elected by the *comitia curiata*. Their insignia of office were the same as those of the kings had been, namely, the purple robe called the *toga prætexta*, and the chair ornamented with ivory, or *sella curulis*. They had the care of the temples, baths, porticoes, aqueducts, sewers, and roads of the city. They presided at the religious celebrations, of which theatrical exhibitions formed an important part; and, in performing this duty, the ædiles under the republic were often guilty of the most lavish expenditure, with the view of acquiring popularity, and thus paving their way to the higher offices of the state. The plebeian ædiles were, as their name imports, specially magistrates of the *plebes* or commonalty. They were subordinate to the tribunes of the *plebes*, and acted as judges in such causes as were referred to them by their superiors. The temple of *Ceres*, which constituted the treasury of the commonalty, was under their peculiar guardianship. They here received the fines paid for offences against the plebeian magistrates, and made a distribution of bread among the poor of their order. In the same temple, too, they preserved the public records connected with their own body, and the decrees of the senate. The care of the public buildings and streets on Mount Aventine and in the immediate neighbourhood, which in early times formed the chief residence of the commonalty, and was without the limits of the city, must have been, we may infer from their title, entrusted to the plebeian ædiles. Their persons, like those of the tribunes, were inviolable. There were other duties connected with the office of ædile, whether curule or plebeian, such as the inspection of the markets, and the superintendence of the corn trade, the examination of weights and measures, the registration of courtesans, and perhaps the general management of all matters of police in Rome and the suburbs: they had, of course, their courts for inquiring into and punishing offences connected with their office. The curule ædileship was the second in the series of honours through which the Roman candidate proceeded to the consulship; and the laws required an interval of a whole year after the close of the quæstorship, before any one could be a candidate for the ædileship. The title of ædile was known also in the municipal towns of Italy.

ÆGINE'TAN ART. Several ancient writers, particularly Pliny and Pausanias, make frequent mention of Æginetan works of art; and in such a manner, as to show that the productions of the school of Ægina, to use a modern and well-understood phrase, were highly esteemed. Many names of Æginetan sculptors had thus come down to us as almost synonymous with excellence in their art, but the works of none of these could be recognised among those which had escaped the ravages of time and the desolation of barbarism; so that their merits and reputation rested on report alone. The discovery of the sculptures which adorned the tympana of the supposed Panhellenium, the national temple of the Æginetans, was believed, however, to have furnished us with undoubted specimens of Æginetan art, and of that period too in which the most celebrated Æginetan sculptors flourished. This conclusion there is reason to think was too hastily adopted. That the sculptures referred to are of great beauty and merit, and are for many reasons highly interesting, will be admitted by all; but that they are of the class and date from which the school of Ægina derived its celebrity, may fairly be questioned. It may now be regarded as beyond doubt that the building was a temple of Minerva and not of Jupiter (Müller, 'Archaeologie der Kunst,' s. 90; Wordsworth, 'Greece,' p. 190, ed. 1859), and it is highly probable that it was wholly, or in part, rebuilt by the Athenians when in possession of Ægina. The sculpture is evidently of different dates, and it may be, as has been suggested (Scharf, in Wordsworth, p. 46), that the figures of the western pediment, which are of a smaller size and less advanced in style than those in the eastern, are really Æginetan works; while those in the eastern pediment are by Athenian sculptors.

The figures principally consist of perfect statues, or statues in the round, as they are termed; those in the eastern pediment about the size of life, those in the western somewhat smaller, of men armed with spears, swords, shields, and bows. The bowmen have quivers of arrows suspended from their waists; most of the figures are helmed or bonneted, some with greaves on the legs, and two or three with armour on the body, or close-fitting garments on the body and limbs; but for the most part they are naked, except the head, and all are either engaged in active combat or have fallen from the effect of wounds. Besides the male combatants, one helmed and draped female figure, with a spear and a shield in her hands, and the helmed head of another, evidently belonged to the groups. These were all so distributed on the ground with reference to the temple, and are of such peculiar attitudes with respect to one another, and to the places they occupied, that there appears to have been no great difficulty in determining their original arrangement in groups, after the fragments into which many of the figures were broken, were once brought together; especially as the frames which inclosed the pictures they formed, were otherwise determinable, and thus assisted materially in fixing the relative positions of the parts composing the groups. Thus, the perfect female figure, evidently a statue of Minerva, standing upright and in full face, occupied the central position under the highest part of the tympanum of the western pediment; and the combating warriors of that end arranged themselves on her right and left, in attitudes upright and advancing, kneeling, stooping, and falling, until the inner acute angles terminated in the wounded and recumbent. The goddess stands in quiet dignity, prepared, nevertheless, for action, while the battle, of which she appears to be the umpire, rages around her. Of this picture or group, the arrangement is so fitting and complete, and the action so perfect, that there is no reason to think, that any essential portion of it is undiscovered. But unfortunately it is not so with the group of the eastern or principal front; a few only of these figures can be restored, and it is only from the analogy afforded by the western group, that their arrangement can be aptly determined. As far as the figures can be made out, the persons seem to be nearly, if not quite, identical, and another period of the same action appears to be represented. The helmed female head is that of Minerva again, and Mr. Cockerell restores her figure as in the act of raising her spear and extending her vest, as if to stop the contest, or to protect the fallen. The exact subject or subjects intended by these groups, is not known: though all the critics who have offered opinions seem to agree that they represent some actions of the distinguished Æginetan family of heroes, the Æacidæ, or descendants of Æacus, the mythological founder of the nation. Colonel Leake's opinion, as given by Mr. Cockerell ('Journal of Science and the Arts, No. 12, p. 334, note), is that they represent two periods in the contest over the body of Patroclus, from the 'Iliad,' in which Ajax (one of the Æacidæ) and Hector were the principal combatants: that this was the subject of the western pediment, there can be little doubt. That something connected with the Trojan war is intended in each, seems very evident, from the Phrygian bonnet worn by one of the warriors; and the greaves on the legs of those who may be supposed to be Greeks, in the eastern group, especially, and the absence of this covering on the figures of the opposite party, seem clearly indicative of their national difference. Thiersch's opinion is, that the group on the eastern pediment represents the expedition of Telamon, the son of Æacus, and Hercules, against Laomedon, king of Troy. The archer he considers to be the representation of Hercules. The other group, he thinks, may represent the death of Achilles, and the struggles of Ajax to save his body from the Trojans. (Thiersch's 'History of Greek Sculpture,' p. 249, note.) The sculptures are now in Munich, having been purchased by the late king of Bavaria, when crown prince. Such of the statues as were capable of repair were very carefully put together, and the deficient parts supplied by Thorwaldsen. Casts of the figures, as restored, are placed in the Phigalian Saloon of the British Museum, within two tympana of exactly the same form and dimensions as those of the eastern and western ends of the temple at Ægina, in which they originally stood.

There is scarcely anything in the combination of sculpture and architecture more admirable than the manner in which the various actions and attitudes, in the western group of the figures, have been adapted to the situations which they occupied; and this too, without the slightest appearance of constraint; they are all natural and graceful, and in perfect keeping with the design of the subject, and the character of the architecture. The energy of action, the grace of attitude, and the truth of proportion displayed in these works, are also admirable, and the expression of many of the figures is excellent. But there is a degree of dryness and rigidity observable in the bodies and limbs, which give the works an archaic character, whilst the countenances, the hair, and the draperies, clearly betoken their near approach to, if not absolute connection with, the archaic period. The faces are almost entirely devoid of expression, the lips are thick, the nose is short, but angular and prominent; the eyes are protruded, the forehead is flat and retiring, and the chin is long and pointed; the hair is formally laid in tiers with convoluted ends, and the draperies, though not devoid of grace, are heavy and monotonous. (Lyon's 'Outlines of the Ægina Marbles.') Now these are peculiarities which could scarcely have existed in the works of men whose names are mentioned with those of Phidias and his compeers and immediate successors; but they pretty clearly mark a more remote period. The comparative fulness of form, and freedom of action of the bodies and limbs of the figures in the eastern pediment, indicate, on the other hand, a date not far removed from excellence. On every part of the figures, except the face, traces of colour are plainly discernible; there are holes in many of the figures for affixing bronze armour, and the hair was partly of wire.

The temple of Ægina is described and figured at the end of the article ÆGINA, in the GEOGRAPHICAL DIVISION of the ENGLISH CYCLOPÆDIA, vol. i. col. 72, &c.

ÆNEID, the most celebrated epic poem of antiquity, after the 'Iliad' and 'Odyssey.' It was written by Virgil in the time of Augustus Cæsar; and relates the wanderings of Æneas after the siege of Troy, his arrival in Italy, and his adventures previous to his marriage with Lavinia, with his final establishment in Latium. The poem, however, does not carry its hero so far as this, but closes with a single combat between Æneas and Turnus, and the death of the latter. In some respects Virgil has deviated from the legend related in the article ÆNEAS. [BIOG. DIV. ENG. CYCL., vol i. col. 46.] He has multiplied the Trojan ships and increased the number of the Trojans; he has carried his hero to Carthage, though we do not know whether Carthage existed at the supposed date of Æneas's wanderings: he has made the death of Turnus precede the marriage of Æneas and the foundation of Lavinium, and has allowed Latinus to survive, instead of making his daughter wed the author of her father's death. The poem consists of twelve books, of which the first six are occupied in relating the wanderings of Æneas, and seem to be modelled on the 'Odyssey;' the last six contain his descent into Italy, and the war which ensued between the Trojans and the natives, and seem to be modelled on the 'Iliad.' In the minute details of ornament as well as in the general notions of his work, Virgil has borrowed largely from Homer. This poem was written later than his other works, the 'Eclogues' and 'Georgics.' It was commenced about A.U.C. 724, or B.C. 30; and the author continued to labour on it till his death, in B.C. 20; at which time he was so little satisfied with the state of his production that, it is said, he gave earnest injunctions on his death-bed that it should be burnt. The order was not fulfilled, at the desire of Augustus, who intrusted the publication to two learned friends of the author, Tucca and Varus. Many lines are left imperfect; some suppose this to be one proof that the finishing hand of the master was never applied; but we doubt whether it is, and think it possible that they were purposely left so. This great work of Virgil called forth the enthusiastic admiration of his contemporaries. Propertius wrote—

"Yield, Roman poets; lords of Greece, give way;
The Iliad soon shall own a greater lay;"

and some writers, even in modern times, have expressed the same opinion. It is enough to say that, compared with the 'Iliad,' the 'Æneid' is wanting in originality and power; it is the laboured performance of a learned man, possessed of an elegant mind, who has availed himself freely of the labours of those who preceded him. Virgil is characterised by Niebuhr as possessing "a genius barren for creating, great as was his talent for embellishing." The characters of the 'Æneid' are deficient in the individuality and freshness which mark the description of those who have mingled in scenes and been familiar with characters such as they portray. The brave Gyas and the brave Cloanthus are hardly distinguishable, except by name: Achates, the friend of Æneas, is a mere shadow, always attending on his chief; and, indeed, with the exception of Dido, no character is well defined. Æneas himself, though the hero of the poem, neither excites any strong interest nor leaves any powerful impression. In this respect Virgil is immeasurably inferior to Homer. The strength of Virgil lay in the pathetic rather than in the sublime; and many passages of the 'Æneid,' which admitted of the former quality, are exquisitely beautiful.

The 'Æneid' has been frequently translated into most European languages. In our own, we may notice one peculiarly interesting to the literary antiquary; a translation, by Gawin Douglas, Bishop of Dunkeld, of the whole 'Æneid' into the old Scottish dialect, about 1512; and said by Warton to be the first translation of a classic into the language of Britain. The Earl of Surrey translated the second and fourth books, printed in 1577. There are complete translations by Ogilby, Pitt, &c., but the energetic version of Dryden has nearly superseded all others.

ÆNI'GMA, a Greek term for what is commonly called a Riddle. It is the description of a thing by certain of its qualities selected and disposed, with the object of hiding what the thing is, and of occasioning its discovery to come as a surprise.

An ænigma differs from a definition or other direct statement, not in being false, but only in being obscure and misleading. The one is an instance of the application of language to make known our thoughts, and the other of its application to the purpose of concealing them; but the words of a good ænigma, when properly understood, are as true as those of a good definition. It is also an indispensable quality of the latter, as well as of the former, that it shall be intelligible, in its whole import, only in one sense.

The object of a direct statement is to convey information; that of an ænigma is to exercise the ingenuity. The former, in its simplest and most legitimate form, has only to be received by the mind; the latter demands to be solved. An ænigma, therefore, may be regarded as one of the complex or ornamented modes of composition, that is to say, one of those which do not merely appeal to the apprehension, but excite and gratify other intellectual faculties.

In very ancient times, accordingly, the ænigma was a common and favourite medium for the conveyance even of truths of the highest importance. Formal composition in the earliest state of society, that it might be the better distinguished from ordinary speech, naturally affected an elaborately artificial character; and the ænigma or riddle presented itself among other devices for that end. It had, besides, the peculiar recommendation of giving an air of mystery to the sentiment which it involved, and so making it seem to be something still more remote than it might really be from common experience and speculation. The term ænigma, indeed, was probably used originally to describe any short composition, such as apologue, or fable, or other portable sample of wisdom or entertainment. Ænigma is something dark and obscure, and the corresponding verb (αἰνίττεσθαι) always means *to speak ænigmatically*, according to our meaning of the word, or to speak with a certain degree of mystery and obscurity.

In the progress of civilisation and literature, it came to be felt that obscurity and difficulty were qualities which, whatever pleasure they might convey to those who tried to master them, were inconsistent with all the higher and more appropriate objects of speaking and writing. Whether the purpose be simply to communicate information, or whether it be to appeal also to the imagination and the passions, a style is good exactly in proportion as it is expressive, that is to say, as it conveys directly and completely the thoughts of the writer or speaker. The ænigma, therefore, the very end and nature of which is the reverse of this, instead of being an ornament, must be regarded as one of the worst faults of style. Whatever approaches towards the ænigmatical, is, for the same reason, a fault in writing—whatever figure, for example, is introduced in poetry or rhetoric more in order to surprise the reader by its ingenuity than for any other purpose. Amongst those writers who have vitiated their works by what may be called an ænigmatic turn of phraseology, Young is an instance, in his 'Night Thoughts.'

ÆO'LIAN HARP, a musical instrument, the sounds of which are drawn from it by a current of air acting on the strings. In the last century, the Æolian Harp was brought forward in London as a newly invented instrument; and Dr. Anderson, in a note to Thomson's 'Ode on Æolus's Harp,' ascribes the invention of it to Mr. Oswald. However, it is possible that an instrument of the kind was very anciently known; for the Talmudists say that the *kinnor*, or harp of David, sounded of itself when the north wind blew on it. But the merit of the invention in the form it now takes, is due to Athanasius Kircher, who describes it in his 'Musurgia Universalis' (lib. ix. 352).

The following are detailed directions for the construction of the Æolian harp: Let a box be made of as thin deal as possible, of a length exactly answering to the width of the window in which it is intended to be placed, four or five inches in depth, and five or six in width. Glue on it, at the extremities of the top, two pieces of oak, about half an inch high and a quarter of an inch thick, to serve as bridges for the strings; and withinside, at each end, glue two pieces of beech about an inch square, and of length equal to the width of the box. Into one of these bridges fix as many pegs, such as are used in a pianoforte, (though not so large), as there are to be strings; and into the other, fasten as many small brass pins, to which attach one end of the strings. Then string the instrument with small catgut, or *first* fiddle-strings, fixing one end of them, and twisting the other round the opposite peg. These strings, which should not be drawn tight, must be tuned in unison. To procure a proper passage for the wind, a thin board, supported by four pegs, is placed over the strings, at about three inches distance from the sounding-board. The instrument must be exposed to the wind at a window partly open; and to increase the force of the current of air, either the door of the room, or an opposite window, should be opened. When the wind blows, the strings begin to sound in unison; but as the force of the current increases, the sound changes into a pleasing admixture of all the notes of the diatonic scale, ascending and descending, and these often unite in the most delightful harmonic combinations.

A curious suggestion was made in 1857, for playing the Æolian harp by the sun's heat instead of a current of air. Provide a leather case, which should be so made as to join the harp in the form of a trough, extending from one end to the other. This case must be air-tight, and must have at its furthest extremity a valve opening inwards. The sun's heat, expanding the air in the case, will (according to this supposition) cause it to act upon the strings, and produce the sound; while the pressure of the external atmosphere will open the valve, to supply the case with air.

Dr. Matthew Young entered fully into the principle of the Æolian harp in his 'Enquiry into the principal Phænomena of Sound.' In what way different sounds can be heard from the same string, without any fingering or pressure, he thus explains: "Let us consider what will be the effect of a current of air rushing against a stretched elastic fibre. The particles which strike against the middle point of the string will move the whole string from its rectilineal position; and as no blast continues exactly of the same strength for any considerable time, although it be able to remove the string from its rectilineal position, yet, unless it be too rapid and violent, it will not be able to keep it bent: the fibre will, therefore, by its elasticity, return to its former position; and by its increased velocity, pass it on to the other side, and so continue to vibrate and excite pulses in the air, which will produce the tone of the entire string. But if the current of air be too strong and rapid, when the string is bent from the rectilineal position, it will not be able to recover it, but will continue bent and bellying like the cordage of a ship in a brisk gale. However, though the whole string cannot perform its vibrations, the subordinate aliquot parts may; which will be of different lengths in different cases, according to the rapidity of the blast. Thus when the velocity of the current of air increases, so as to prevent the vibration of the whole string, those particles which strike against the middle points of the halves of the string, agitate those halves as in the case of sympathetic and secondary tones; and as these halves vibrate in half the time of the whole string, though the blast may be too rapid to admit of the vibration of the whole, yet it can have no more effect in preventing the motion of the halves, than it would have on the whole string were its tension quadruple; for the times of vibrations in strings of different lengths, and agreeing in other circumstances, are directly as the lengths; and in strings differing in tensions, and agreeing in other circumstances, inversely as the square roots of the tensions, and, therefore, their vibrations may become strong enough to excite such pulses as will affect the drum of the ear; and the like may be said of other aliquot divisions of the string."

ÆO'LIAN MODE, in ancient music, one of the five principal modes of the Greeks, which derived its name from Æolia, a country of Asia Minor. Authorities differ most essentially as to the character of this mode. Rousseau says it was grave; the Abbé Feytou contradicts him; Sir F. Stiles tells us that this mode was the same as our E flat; Dr. Burney makes it F minor; and Rousseau says F, meaning, of course, F major. [MODE.]

ÆOLI'NA, a very small musical instrument, consisting of a number of short, elastic, metallic laminæ, or springs, fixed in a frame, and acted on by the breath of the performer. The best of the kind comprise three octaves of diatonic sounds, and are also capable of giving the three simple harmonies of the key. This instrument was the first formed on such a principle that appeared in England, and became exceedingly popular for a time; but was superseded by a much more perfect thing of the kind, the accordion, in which the impulse of air is managed by bellows or a wind-chest instead of by the breath. [ACCORDION; CONCERTINA.]

ÆOLIPYLE, ÆOLIPILE, *Æoli pila, the ball of Æolus*, an instrument made use of formerly in experimenting, consisting of a hollow ball, with a small orifice in which a tube might be screwed. It served to boil water in, for the purpose of creating steam. This instrument is mentioned by Des Cartes, in his treatise on 'Meteors,' chap. iv., as used in his time. It is now entirely out of use, unless we choose to consider the boiler of a steam-engine as an ælopile. This is by no means the first instance in which a philosophical toy has been made of use to the arts.

ÆRA, a point of time from which *subsequent* years are counted, and in some instances *preceding* years, as in the Christian æra. The origin of the word *æra* is very doubtful.

All nations who have any history to record have fixed their æra at some remote period, in order to embrace in their annals as large an extent of time as practicable. The creation of the world would most naturally present itself to those who might have any means of ascertaining the time of its occurrence, and the Bible would be the source from whence the information might be obtained. But, unfortunately for chronology, the Bible is not sufficiently explicit on the subject; and, although the Jews and some Christian nations do date from the Creation, their computations of the period at which this event took place differ to the extent of nearly 2000 years. Those whom this uncertainty has deterred, or who have had no knowledge of the Scriptures, have contented themselves with more recent periods. The ancient Romans adopted the epoch of their first supposed political existence, and the Greeks that of the first celebration or revival of the Olympic Games, which were with them an important national festival. Many nations have assumed some event closely connected with their religious faith: thus, the early Christians of the East dated from the persecution under the Emperor Diocletian, and those of Europe and America, at the present day, from the birth of Christ. All the followers of Mohammed have adopted, as an æra, the retreat of their prophet from Mecca to Medina, which they call the Hegira.

Many of these æras are arbitrarily and incorrectly fixed, and even our own is erroneous by four years. But an error at the commencement will not invalidate the dates of events recorded subsequently, as any æra once assumed will be sufficient to show the succession of time, however incorrectly assigned to the period whose name it bears.

With one or two exceptions, all nations have reckoned time in accordance with the course of the seasons; they have always begun their year at the same season, sometimes perhaps a little earlier, and sometimes later, but invariably keeping near the original commencement.

Here follows a list of the æras which have been or are most in use among the civilised nations of the world, with the year of the Christian æra in which they began:—

1. The year of the world according to the reckoning of Constantinople, which was used in Russia until the beginning of the 18th century, and is still employed by the Greek Church . . . . B.C. 5509
2. The year of the world as reckoned at Antioch, now used in the Abyssinian Church . . . . . B.C. 5492

[The Church of Alexandria originally assumed the year B.C. 5502 as the year of the Creation, but in the year A.D. 285 they discarded ten years, and thus acceded to the computation of Antioch.]

3. The year of the world used by the Jews . . . . B.C. 3761
4. The Caliyuga, employed by the learned throughout India, may be called an æra of the Creation, being considered by the Hindoos as the commencement of the present state of the world, or 'Iron Age' . . B.C. 3102
5. The Olympiads; the æra of the victory of Corœbus at the Olympic games, used chiefly by the Greek historians after the age of Alexander . . . . . B.C. 776

[N.B. An Olympiad is a period of four years.]

6. The Building of Rome: this is generally called the Varronian æra . . . . B.C. 753
7. The Catonian æra of the building of Rome is* . . B.C. 752
8. The æra of Vicramaditya, in common use throughout India . . . . B.C. 56
9. The Spanish æra, from the Conquest of Spain by Augustus, was employed in Spain, Portugal, Africa, and the South of France. In some provinces this æra was in use until the middle of the 15th century. B.C. 38
10. The æra of Salivahana, in common use through the southern and western states of India . . . . A.D. 78
11. The æra of Martyrs, or of Diocletian, so called from the persecution of the Christians in the reign of that emperor, was much used by the early Christians, and is still employed in the churches of the East . . A.D. 284
12. The Hegira, used by all Mohammedans, dates from the flight of Mohammed to Medina . . . . . . A.D. 622
13. The Christian æra dates from the birth of Christ; the year in which he was (erroneously) supposed to be born is called 1 B.C., the following year 1 A.D. Many authors call the year of our Lord's birth 0, and consequently make the dates of all preceding events one year less than by the common practice.

* See Ideler's 'Chronology,' p. 334.

The following rules will serve to show the year of the Christian æra corresponding with that of any given æra:—

1. When the commencement of the given æra precedes the birth of Christ, subtract from the given year the number affixed to the æra in the above list, and the remainder will be the year of Christ in which the given year began.

If the given year be less than the affixed number, subtract it from that number, adding one; the result will be the date before Christ.

Examples.—Required the Christian date answering to the year of Rome 1754.

From 1754
Deduct 753

The year 1001 A.D. corresponds with the year 1754 A.U.C.

Required the year B.C. answering to 707 A.U.C.

From 753
Deduct 707

46
Add 1

The year 47 B.C. coincides with 707 A.U.C.

The reason is this: A.U.C. 707 means that an event took place *in* that year: and therefore 753—706 or 47 years B.C. remain, and as all the years B.C. *before* B.C. 47 have expired, the event must take place *in* the year B.C. 47.

Required the year of Christ in which the year of the Jews 5613 began.

From 5613
Deduct 3761

Answer A.D. 1852

2. When the commencement of the given æra follows the birth of Christ, add to the given year the number affixed to the æra in the list, less one. The sum will be the year of Christ in which the given year began.

Example.—Required the Christian year in which 1031 of Martyrs began.

To the given year 1031
Add the number in the list less one 283

The year A.D. 1314 answers to the year 1031.

All the above dates may be reduced to the Christian æra by the same formula, except that of the Hegira, as the Mohammedans allow only 354 days to the year. Mohammedan reckoning is thus at variance with the course of the seasons; their year now (1859) begins in July, and gains at the rate of a little more than three years in a century. It will, therefore, be necessary to prepare any given date from the Hegira by subtracting three years for every hundred, before reducing it to the Christian æra.

Required the year of the Hegira 1268.

From 1268
Subtract 3 years for every hundred 38

1230
Add the number in the list less one 621

1851
The year of the Hegira 1268 began in the year 1851 A.D.

3. The computation by Olympiads may be thus explained: for instance, Ol. lx. 3 means that an event took place *in* the *third* year of the *sixtieth* Olympiad, and consequently *in* the year that followed the expiration of 59 Olympiads (or 59 periods of 4 years each), and 2 more years belonging to the 60th Olympiad; or after the expiration of 238 years, and therefore *in* the year B.C. 538.

AËRATED WATERS. The term mineral waters has generally been applied to those drinks in which water is combined, naturally or artificially, with mineral ingredients having medicinal qualities; but when the water is simply impregnated with gases, the term aërated waters becomes preferable.

Bakewell's apparatus is one among many contrivances for producing such liquids, for effervescing, aperient, tonic, and other purposes. Let us select the manufacture of soda-water, as one example: The apparatus employed consists of an upright vessel supported on a stand, and furnished with pipes and valves. In the lower part of the apparatus is a vessel called the generator, divided into two compartments by a horizontal partition. Sulphuric acid is placed in the uppermost of these compartments, and carbonate of soda in the lower. While the vessel is at rest, the two substances are kept wholly separate; but when a working motion is given to it by making it oscillate on two pivots whereby it is suspended, the acid drops at regular intervals through a hole in the side of the upper compartment, and falls into the lower one, where it mixes with the carbonate. A chemical interchange immediately takes place; the soda leaves the carbonic acid and combines with the sulphuric; so that, instead of sulphuric acid and carbonate of soda, we obtain carbonic acid and sulphate of soda. The carbonic acid assumes the gaseous form, and ascends to an earthenware vessel in the upper part of the apparatus. This vessel contains water; and as the apparatus is kept oscillating, the water is sufficiently agitated to absorb the gas passed up into it. With a small apparatus capable of holding a gallon at a time, a quarter of an hour's oscillation will suffice to impregnate the water with gas to a pressure of five atmospheres. The apparatus must of course be strong to resist this pressure; it is made of iron, and there is a pressure gauge at the top, to measure the amount of the pressure. There is a tap for draining off the aërated liquids. Dr. Venables states that for a gallon of water to be impregnated to the extent of five atmospheres, would require about six ounces of carbonate (or rather sesqui-carbonate) of soda and four ounces of sulphuric acid. The apparatus admits of being used in many ways; for the aërator or upper vessel may be either filled with pure water, and modified only by the gas which ascends from the generator, or the water may previously be made acid or alkaline, and receive a further change by the aëration. The resulting beverage will thus depend, not only on the aëration, but also on the state of the water before aëration.

Numerous other machines have been introduced for making and bottling soda and other aërated waters. Messrs. Cooper and Bursell, Messrs. Mayo, Messrs. Tylor and Son, Messrs. Tyler and Hayward, Messrs. Masters, and Mr. Cox, are all patentees of apparatus of this kind; and M. Savaresse and other manufacturers in France have displayed their ingenuity in a similar direction. The first-named manufacturers have patented an aërating machine and a carbonating machine, adapted to the manufacture of aërated waters. Messrs. Mayo's patent siphon vase, for containing aërated waters, and made by a combination of metal and pottery, affords the means of withdrawing at pleasure such quantity of the beverage as may be required, and keeping the rest in a state fit for effervescence. Messrs. Tylor and Son have invented a small fountain soda-water machine, a double soda-water machine (with a gasometer similar to those used in gasworks), and a bottling or corking machine. Messrs. Tyler and Hayward have a double soda-water machine for two bottles, capable of making 300 dozen per day.

There are two or three of these machines which deserve a little attention for the ingenuity displayed in them. In Cox's apparatus the impregnating gas may be sustained at a pressure sufficient to cause its absorption by the liquid to be aërated without the aid of force-pumps. The machine can aërate 50 gallons in an hour. There is a vessel called a generator, in which lime-water is placed; another vessel containing dilute sulphuric acid; a third vessel, the purifier, containing water; and a fourth, containing the liquid which is to be aërated. The acid is admitted into the generator, where it is kept agitated or stirred with the lime-water; carbonic acid gas is formed by the decomposition of the lime, and is admitted into the purifier, where it is cleansed from some of its impurities by passing through the water; the gas then passes into a cylinder containing the liquid to be aërated, where a constant agitation is kept up to facilitate the aëration. The gas is generated under such circumstances as to give it an intense pressure, which renders necessary great strength in the apparatus. There are contrivances in the cylinder for facilitating the bottling of the aërated liquid.

Messrs. Masters's aërating apparatus is very simple in construction, and is adapted for domestic rather than for manufacturing uses. It consists of two globular-shaped glass vessels, the upper one of which receives the water to be aërated, while the lower is that in which the gas is generated. The machine can hold about liquid enough for six ordinary tumblers or goblets. To make soda-water, the upper globe is filled with the proper liquid, and the materials for generating carbonic acid are introduced into the lower; there is a connection between the two globes, which are in other respects air-tight. The aëration or carbonating is speedily effected, and the soda-water can then be drawn off at pleasure by means of a patent siphon tap worked by a spring. Any kinds of beverage, such as wine, lemonade, nectar, ale, beer, &c., can be brought into an effervescing state in a similar way; and the ready mode in which this is effected constitutes a recommendation of the machine.

M. Savaresse's machine aërates from 300 to 3000 bottles per day, according to its size. It is intended for the aëration or effervescing of drinks generally; it is somewhat complex in arrangement, but can be worked by one person. Belonging to but detached from this is a vessel called a *siphoid*, to transfer the aërated liquid to a glass; the siphoid is filled from the large machine, and may then be emptied by glassfuls without any deterioration of quality.

Messrs. Knight patented an air-tight stopper in 1844, for flasks intended to contain the aërated water, when required to keep it some time for further operations, or to transfer it to the common glass-bottles. It is an ingenious piece of apparatus, strong enough to resist the expansive force of the gas, yet easily adjusted for the entrance or exit of liquids.

AËRIAL IMAGES is a term applied to those images which are caused by the convergence of reflected or refracted rays of light, when they appear to be suspended in the air. [LIGHT; MIRAGE.]

AËRIAL PERSPECTIVE, a term in painting, implies, in its simple definition, the receding of objects into distance, as seen through the medium of air. In its general application, however, it is to be understood in a more enlarged sense. Linear perspective may be considered the material guide of the artist, originating in, and governed by, mathematical science; but aërial perspective is, in whatever relates to *effect*, amenable to no positive law or established rule, and depends for its application on the perceptions and capacity of the artist. Although entering into every variety of subject, in graphic representation, it is in open scenery that aërial perspective is exhibited in its proper sphere. To feel this, it will only be necessary to recollect in how different an aspect the same scenery may present itself under different modifications of the atmosphere. A prospect, which at noon day, or in a clear and bleak morning, appears tame and uninteresting, will often assume an ideal character, and start into combinations of beauty, if seen at sunrise or at sunset, or under the influence of any atmospheric phenomenon favourable to the development of picturesque effect.

It is, of course, in those schools of painting, wherein the study of external nature, especially of landscape, has been most cultivated, that we are to look for the finest examples of aërial perspective. The Roman and Florentine masters, whose object, almost exclusively, was human form and character, seem to have felt or understood but little of it. The Dutch and Flemish painters exhibit very considerable excellence in this particular, as is shown in the works of Rubens, Rembrandt, Cuyp, Ruysdael, &c. France, however, has the glory of having produced the artist Claude Lorraine, who, in this great quality of art, bore off the palm from all competitors. He rarely painted any other effects than those of the rising or the setting sun; but whatever be his subject, an ancient port, or ruins, or temples, the great and presiding charm of Claude is his consummate skill in aërial perspective; but the aërial perspective of a calm and placid atmosphere. If there be any of the older masters who, in the treatment of aërial perspective, can compete with Claude, that competitor, perhaps, is Cuyp. His pictures are direct portraits of the scene before him,—the willowy lake, the marsh, the meadow, the drowsy shepherd, and the ruminating cow. But, in spite of the simplicity of these materials, and an horizon, in general, perfectly flat, he communicates to his works an effect of air and distance, and consequently of reality, which must rank them among the most remarkable efforts of art. To these may be added the English Wilson, whose mastery in the practice of aërial perspective, gives him a right to rank with Claude and with Cuyp in this quality; and Turner, whose representations of a wide expanse of country under the influence of atmospheric phenomena, are unequalled by any painter, ancient or modern, for the almost unlimited variety of their range, and the brilliancy and accuracy of their aërial effects. Indeed, in his numberless oil paintings and water-colour drawings, nearly every variety of aërial effect, from the calmest and most unruffled sky to the fiercest tempest, may be found represented with the most surprising force and fidelity—allowance being made for occasional exaggeration of colour—the accurate perception of the relative distances of the various objects, and whatever is understood under the term aërial perspective being still strictly maintained.

AËRO-DYNAMICS, signifies the science which treats of the motion of the air, or of the mechanical effects of air when in motion. In its widest sense, it might be taken to include the effects of the motion of any gaseous substance or vapour; and even the properties of steam might be considered as a part of the science. We shall however confine ourselves to the explanation of the few general principles which can be relied upon, with regard to air *alone*, leaving the others for their proper places, with their chief applications, such as ANEMOMETER, WIND-MILL, AIR-GUN, SAIL, STEAM-ENGINE, RESISTANCE, GUNNERY, &c.

If there be one part of dynamical science more abstruse than another, it is the doctrine of the propagation of motion in fluids, especially elastic fluids, like the air. In this case, the acting forces may be said to consist (1) in local dilation of parts of the atmosphere by the sun's heat during the day, and contractions by cold during the night; (2) in the permanent difference in temperature of the equatorial and polar regions; (3) in evaporation from some parts of the earth's surface, by which the air, being entangled, so to speak, in the meshes of the vapour, is displaced upwards, and in condensation as rain, &c., in other parts, by which air is carried downwards with a large quantity of transferred latent heat; (4) in the effect of the diversities of land and sea, mountains and valleys, lakes and rivers, all of which forces act so as to cause *motion* in the aërial ocean; (5) in the rotation of the earth on its axis. Vapour introduced into the air by evaporation acts as a moving power in *two* ways: (1) By a simple addition of volume. The tension of the vapour is, by Dalton's law, added to the elastic force of the air. (2) Since vapour of water is of a less specific gravity than air, in the ratio of 0·6235 : 1, being the lightest of vapours, and, except hydrogen and ammonia, the lightest of gases, its upward diffusion is much more rapid than its horizontal, and acts in producing ascensional motion in the air itself.

The dilatation of the air by heat acts rather differently. Air is only dilated by $\frac{1}{10}$th of its bulk by an increase of 50° F., so that its effect in producing up-rushing currents is very small, unless it be violently heated. It, however, acts chiefly by upheaving the superincumbent strata, and causing them to flow over on other cooler regions. For aërial motions caused by the earth's rotation, see WIND, TRADE-WINDS.

For the tide-waves produced in the atmosphere, by the attraction of the sun and moon, see PNEUMATICS; METEOROLOGY.

As soon as we begin to move, we feel more or less the resistance of the air. At an ordinary rate of motion this is not very perceptible; but the jockey, who rides at the rate of from thirty to forty miles an hour, feels it sensibly, and is obliged to wear a cap which may *cut* the wind, as the bow of a ship *cuts* the water, or otherwise it would be blown off his head, although, in the common sense of the word, there might be no *wind* stirring at the time. Whenever we attempt to put any matter in motion, we feel what is denominated *pressure*, or *resistance*, which is the greater, the greater the quantity of matter which we attempt to move, and the velocity which we attempt to communicate to it. Thus, two violent pressures, of equal force, applied for an instant to weights of ten and twenty pounds, will make the weight of ten pounds move twice as fast as that of twenty; or, if we would have the two move equally fast, we must apply twice as much pressure to the twenty pounds weight as to that of ten pounds. If we now conceive a number of equal balls placed in a line, along which we move the hand uniformly, so as to set them all in motion one after the other, we might at first imagine that if we move the hand at the rate of two feet in a second, and afterwards at the rate of four feet in a second, that we exert twice as much force, and encounter twice as much resistance, in the second case, as in the first; because, we say, we move each ball in the second case twice as fast as in the first. But there is another consideration: we not only move each ball twice as fast, but we meet with twice as many balls in a second, so that not only the velocity which we communicate in a second is doubled, but also the quantity of matter to which we communicate that velocity is doubled, or, there is four times as much resistance to twice the velocity, as there was to the single velocity. Similarly, at three times the rate of motion, we meet with three times as much matter, and communicate to each portion three times the velocity: whence we meet with three times three, or nine times the quantity of resistance. If we transfer this reasoning to the case of a body moving through the air, we should infer, that the resistance is, to speak mathematically, as the *square* of the velocity: that is, if the velocity be suddenly made ten times as great, the resistance is made ten times ten, or a hundred times as great. And this, which was the first theory proposed on the subject, is sufficiently near the truth for practical purposes, when the velocities are not very great; for example, up to eight or nine hundred feet in a second.

But one or two circumstances have been neglected. (1) The successive particles of air which the moving body strikes, instead of being moved out of the way completely, are forced upon those in front, so that there is a condensation of air before the moving body; which condensation, as we have seen in ACOUSTICS, is propagated onwards at the rate of about 1125 feet in a second. (2) In the meanwhile, the space through which the body moves, or has moved, is, or has been, entirely cleared of air; and though the air is forced with great rapidity into the vacant space, yet this is not done instantaneously, as we shall presently see from experiment. Therefore though, when at rest, the atmospheric pressures before and behind the body counterbalance each other, yet, when in motion, there is an increase of the pressure before the body, and a diminution of that behind it; both which circumstances increase the resistance.

From theory, tolerably well confirmed by experiment, it appears, that if air of the ordinary pressure be allowed to rush into a *vacuum*, or space entirely devoid of air, it will be driven in at first with a velocity of about 1340 feet per second; or, to avoid an appearance of accuracy of which we are not actually in possession, we may say between 1300 and 1400 feet per second. If now, instead of rushing into a vacuum, the air which comes through the orifice meets with other air of a less density, say one-fourth of its own density, the velocity above-mentioned will be diminished in the proportion of 1 to the square-root of $(1 - \frac{1}{4})$, or of 1 to $\sqrt{\frac{3}{4}}$, or of 2 to $\sqrt{3}$, or of 100 to 87, very nearly. By a similar process any other case may be computed. Let us now imagine a ball, *a b* (Fig. 1), to move forwards in the direction BA, with an initial velocity less than 1000 feet per second.

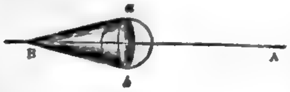


Fig. 1.

Let B be the last point of its track at which the air has completely recovered its former state. The air in the cone B*ab* will not have entirely recovered its state, but will all be more or less rarefied; so that in addition to the loss of motion arising from communication to the particles of air, there is a part of the atmospheric pressure on the front of *ab*, not counterbalanced from behind. The condensation in front of *ab* is propagated [ACOUSTICS] quicker than the ball moves; so that the air in front continues, if not entirely, at least very nearly, in its natural state. We cannot say that the cases of air rushing through an orifice into a vacuum, and of air filling up the space left by a ball, have any decided similarity; nor can we say the contrary, owing to the very imperfect state of the mathematical analysis of this part of the subject. We may however conjecture that when the ball moves with a velocity greater than that of sound, thereby condensing the air before it, and leaving a perfect vacuum behind it, or nearly so, the resistance will be much greater than the theory already stated would lead us to expect. And this proves to be the case at even less velocities than the one just specified; for though up to 1000 feet per second, or thereabouts, the resistance increases very nearly with the square of the velocity, yet from that point it increases in a much quicker ratio; so that to a ball moving at the rate of 1700 feet per second, it is three times as great as we should obtain from our first hypothesis. The resistance to an iron ball of twelve pounds weight, moving at the rate of twenty-five feet per second, is equivalent to a pressure of half an ounce avoirdupois; if we increase twenty-five feet per second to 1700 feet per second, or multiply the first sixty-eight times, the square of which is 68×68 or 4624, we might, from what has been stated, expect a resistance of 4624 half ounces, or $144\frac{1}{2}$ pounds; instead of which it was found to be $433\frac{1}{2}$ pounds; about three times the preceding, as we said. At a velocity of 1600 feet per second, the resistance was found to be more than twice that given by the theory. Without entering further into details, for which the reader may consult the article GUNNERY, to which they particularly apply—and also without considering the effect which the different forms of bodies have upon the RESISTANCE (to which we refer),—we give some of the conclusions to which Dr. Hutton was led by a long and careful repetition of the experiments of Mr. Robins, his predecessor in the same track. For the method of conducting these experiments, see WHIRLING MACHINE; BALLISTIC PENDULUM.

1. The resistance is nearly in the same proportion as the surface exposed, but a little greater than this proportion on the larger surface. That is, if we take two bodies of the same figure and material (two iron spheres for example), the surface of the second being twice that of the first, the resistance to the larger sphere is a little more than twice that of the smaller, the velocities being the same in both.

2. The round ends and sharp ends of solids suffer less resistance than the flat ends. Thus, the sharp end or vertex of a cone is less resisted than the flat end or base.

3. Two solids, having the parts presented to, or which push the air, the same, are not equally resisted unless the hinder parts are also the same.

Though we have hitherto considered the resistance offered to a body moving against still air, and the pressure which is necessary to maintain it at a given velocity, yet the problem is exactly the same, if we suppose the body to remain still, and the air, or as we now call it, the *wind*, to move against it with the same velocity. Suppose the body to move 100 feet in a second, and that the spectator is carried along without his knowledge at the same rate. He will, therefore, always be in the same place with respect to the body, and will at the same time imagine that the air or wind is coming towards him at the rate of 100 feet per second. The force which, when he imagined the body moving, he called the pressure necessary to maintain its velocity, he will now say is the pressure necessary to steady it against the wind.

If we suppose both the wind and the body to be in motion, the resistance is variously modified, according to the direction of the motions of the two. If the wind and the body move in the same direction, with the same velocity, there is no resistance; for no air is displaced by the body. If the wind move 50 feet per second, and the body 100 feet, the pressure on the body is the same as if it were at rest, with a *contrary* wind of 50 feet per second blowing on it. If the wind and the body move in contrary directions, with velocities of 100 feet, the resistance is that of a wind of 200 per second; and so on. If the spectator move with the body unknowingly, the magnitude and direction which he will assign to the wind is that which will produce such a pressure on the body *at rest*, as it really sustains when in motion. [APPARENT MOTION.]

The following well-known table, first given by Mr. Smeaton in the 'Philosophical Transactions' for 1759, and confirmed by the experiments of Dr. Hutton, shows, in pounds avoirdupois, the pressure which different winds will exert upon a square foot of surface exposed directly against them. The first column is a rough representation of the second.

Velocity of Wind.		Force on one square foot in pounds avoirdupois.	Character of the Wind.
Miles per Hour.	Feet per second.		
1	1·47	·005	Hardly perceptible.
2	2·93	·020	Just perceptible.
3	4·40	·044	
4	5·87	·079	Gentle, pleasant wind.
5	7·33	·123	
10	14·67	·492	Pleasant, brisk gale.
15	22·00	1·107	
20	29·34	1·968	Very brisk.
25	36·67	3·075	
30	44·01	4·429	High winds.
35	51·34	6·027	
40	58·68	7·873	Very high.
45	66·01	9·963	
50	73·35	12·300	Storm or tempest.
60	88·02	17·715	Great storm.
80	117·36	31·490	Hurricane.
100	146·70	49·200	Destructive hurricane.

For the method of obtaining these results see ANEMOMETER.

Let us suppose the square foot of surface to be placed obliquely, so as to make an angle A B C (Fig. 2), with the direction A B of the wind. Let D B represent the velocity of the wind per second. Then, if D E be drawn perpendicular to B C [COMPOSITION OF VELOCITIES] the wind which strikes the plane at B does not strike it directly with its whole velocity, but only with the velocity D E; it being the same thing as if we supposed the wind to be carried directly against the plane with the velocity D E, and at the same time shifted on the surface from C towards B with the velocity E B. This last will only make different particles of air strike the point B, but not with different forces. This line D E is in trigonometry proportional to the *sine* of the angle D B E. Again, if we draw E F perpendicular to D B, the whole of the velocity D E is not in the direction of the wind, A B, but only the part of it D F; the other component, F E, being employed in moving the plane in a direction perpendicular to that of the wind. This line, D F, which represents the *effective* velocity of the wind in the direction A B, is, as the *square* of the sine of the angle D B E, since D F = D E sin D E F = D E sin D B E and D E = D B sin D B E. The line, D F, is a third proportional to D B and D E, so that if we suppose the wind to move at the rate of 100 feet in a second, and the plane to be so inclined that the wind strikes it directly with only 80 feet of velocity, we have, for the real effective velocity 100 : 80 :: 80 : 64, or we must consider this plane as resisting a wind of only 64 feet of velocity. This theory is liable to the objections of the former one, as it does not allow for any condensation, but supposes the particles to disappear after they have struck the plane. Nevertheless, it is found in practice to answer well enough when the plane is not very oblique to the wind. For the mathematician, we may state that the following empirical formula is found from Smeaton's experiments to be much nearer the truth, which, as he will see, is nearly equivalent to the square of the sine of the angle of inclination, when the latter is nearly a right angle. Let the angle of inclination of the surface be θ, and the velocity of the wind V, then the effective velocity is

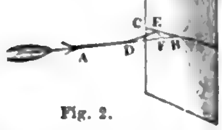

Fig. 2.

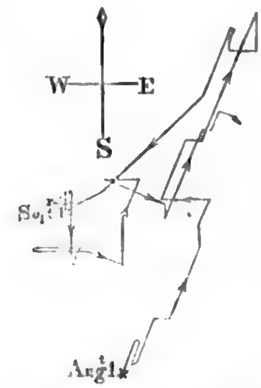
$$V \sin \theta^{1\cdot 842 \cos.} \text{ nearly.}$$

Every meteorological observatory is furnished with an instrument called an *anemometer*, which registers the *direction*, the *duration*, and the *force* of the wind. Hitherto it has not been possible to obtain sufficient data for accurately determining the mean monthly or annual direction and force at a large number of different stations, by reason of the costliness of the apparatus required. Meanwhile, it has been the practice to assume that the force of all winds may be regarded, on the average, as measured by the frequency of their occurrence. Kämtz and Dove have computed the mean annual force and direction, and their monthly variarions, for many stations in Europe and America, of which the following Table is a synopsis :—

	Direction.	Force.
England	S 66° W	0·198
France and Holland . . .	S 88° W	0·135
Germany	S 76° W	0·177
Denmark	S 62° W	0·170
Sweden	S 77° W	0·228
Eastern Europe	N 87° W	0·167
N. of United States . . .	S 86° W	0·182

The mechanical means by which these results are obtained will be described under ANEMOMETER; but we may here state the value of those recorded results in furnishing the *integral* of the wind for each point of the compass; or, in other words, the entire quantity of wind which has blown from each point during a given period. If the force of the wind were constant, the integral would be obtained by multiplying the length of time that the wind blows by the rate at which it travels. The integral is proportional to both these quantities taken jointly, just as the area of a rectangle is proportional to its length and breadth taken jointly. If we were to construct a figure the length of which should represent the *duration* of the wind, and its breadth the *force*, the latter being a constantly varying quantity, the breadth of the figure must vary, in order that its area may represent the integral of the wind correctly. The results furnished by Mr. Osler's anemometer enable us to construct such a figure; but in Dr. Whewell's anemometer the integral is represented simply by the depth which the pencil descends. Whewell's instrument is so far defective that it makes no attempt to record the *time* during which each wind blows, the times of its *changes*, or its *force* at any given moment; but only the order of its changes of direction and the integral or entire quantity that blows from each point, or rather from each rhumb of 11¼° : this is known by the length of the pencil-mark in each vertical division of the cylinder measured vertically and not following the windings of the track, for these must be neglected so far as they are confined to one rhumb, the centre of which corresponds with one of the points of the compass. Hence, any wind which does not deviate from any one of those points more than 5⅝°, if the cylinder be divided into 32 parts, or 11¼° if it be divided into 16 parts, is regarded as blowing exactly from that point; which is a serious defect common to wind-registers. But, supposing that we are in possession of the lengths of line described by the pencil in each division of Whewell's cylinder during a certain period, such lengths or proportionate ones may be laid down in their proper order with directions so as to form a crooked line expressive of all the quantities and changes of the wind for that particular place and period. This is called the *type* of the wind. For example, Fig. 3 represents the type

Fig. 3.

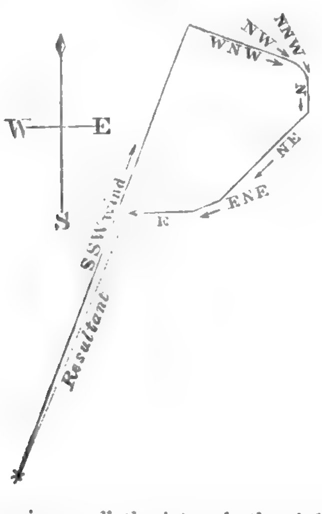


of all the wind that blew over Plymouth during August and part of September 1843. If the two ends of this line be joined by a straight line we shall get the direction of the *resultant* or average effect of all the winds which blew over Plymouth during that period, which, in the case before us, is about N. 23° E. or about equivalent to a S.S.W. wind. This average direction is not, necessarily, the *prevailing* direction or the direction in which the wind most commonly blows; since the prevailing winds may be gentle and the greater force of those from the opposite quarter may more than compensate for their shorter duration, so that the average direction with respect to time and intensity, considered jointly, may differ greatly from the average direction as regards time alone. In England, however, both these averages have nearly the same direction : the time average is equivalent to a wind blowing from some point between S. and W., and the true average, however variable on a comparison of the resultants of different months or seasons, exhibits in the type for a whole year a general northward direction, mostly eastward from the starting point. Whewell's instrument places the mean direction for three years nearer N. than E., while, according to Osler's, it is nearer E. than N.; but when it is considered that in Whewell's instrument the velocity of the fly does not bear a constant ratio to that of the wind, but is more than proportionally quicker in a quick than in a slow wind, while the distance which the pencil descends is proportional to the revolutions of the fly, the traces of the pencil cannot correctly represent the integrals of the wind. In fact, it is necessary to *drive* the instrument by means of a clock, leaving the direction or regulation of the instrument to the wind, as in Osler's instrument.

It will be seen by reference to Fig. 3, in the article ANEMOMETER, that the upper pencil makes a trace on the register paper which represents the pressure of the wind, while the trace made by the middle pencil represents its direction. Now the ordinates of the upper trace are proportional to the wind's velocity; or in other words, the ordinates at any two different moments should bear the same ratio to each other, as did the velocities of the wind at those two moments. Hence, the total amounts of wind passing over the instrument during different periods, will be proportional to the areas of the portions of curve traced during those periods, and it is only by measuring and comparing these areas that we can obtain the proportion of the integrals of wind during different periods of time. To draw a type of the wind by Osler's instrument, such as is so easily done by Whewell's, the periods must be so divided that during each period the direction of the wind may have been confined within certain limits, such as two rhumbs (22½°), or one rhumb (11¼°). To do this that part of the register-paper devoted to direction must be divided by 16 or 32 longitudinal lines, such that when the vane points to any one of the 16 or 32 principal points, the direction-pencil may rest midway between two of these lines; then, by noting all the points where the pencil-track intersects these lines, and from every such intersection raising a perpendicular to the top of the paper, such perpendiculars will divide the upper curve, or that of force, into portions each of which may be regarded as belonging to one wind only; for during its description the wind did not deviate more than 5⅝° or 11¼° (according as we use 32 or only 16 points) on either side of a certain point. By ascertaining the areas of these different portions, and drawing lengths of line proportional to them, placing those lines in their proper direction and in their proper order, we obtain a more correct type of the wind than by the method previously described. The integrals of the wind have not only a relative, but also an absolute value. If the pressure-plate be correctly graduated, as by whirling it through the air at known rates of velocity, and noting the several amounts of compression in the spring, we get similar results to those obtained by having wind at various velocities acting upon the fixed plate. Suppose that the pencil is one inch from the top of the paper when the wind is blowing at the rate of ten miles an hour, two inches when it is blowing at the rate of twenty miles an hour, and so on, and that the paper is moving at the rate of one inch an hour, then every square inch of surface included between the curve of force and the top of the paper denotes that ten lineal miles of air have blown over the instrument; so that by measuring the area of any portion of this surface included between any two ordinates, the *absolute integral* is obtained in miles or the number of miles of air that have passed over the place during the period in which that portion of the curve was traced. Hence absolute values in miles may be assigned to all the lines which form any type of wind, and measuring by the scale thus obtained the length of the resultant or the line which joins the two ends of the type, we obtain not only the *direction* but also the *extent* in miles of the entire movement of air produced by the combined effect of all the winds that have blown during the period for which the type was constructed. " For instance, it was found that the resultant of all the winds that blew over Greenwich, during 1841, was equivalent to the passage of 47,900 miles of air towards E. 28° 30′ N. In the same way the direction of the resultant for 1842 was found to be E. 27° N., and its length 36,750 miles. By dividing these numbers by the number of hours in a year, we see that the total effect of the wind in 1841 was equivalent to a constant current towards E. 28° 30′ N., at the rate of 5·4 miles an hour; and in 1842 towards E. 27° N., at the rate of 4·2 miles an hour; or, in other words, as if there had blown during these two years a constant wind from W.S.W.¼S. at 4¾ miles an hour." The average velocity of the wind at Greenwich during 1841 was 18·7, and during 1842 18·3 miles an hour, while the whole integrals of wind for those years, as shown by the length of their type-line measured along all its windings, was in 1841 167,322 miles, and in 1842, 159,950 miles; showing that the whole movement of the air in this country, is about four times as great as its resultant or effective movement.

The resultant for any given period may, however, be obtained without constructing such a type as Fig. 3. Such a figure may be simplified by

Fig 4.



collecting and summing up all the integrals that belong to the same wind, and then drawing lines proportional to the 16 or 32 sums thus obtained, when, by arranging them in their proper directions, we may get the same resultant as if the whole type had been drawn. The figure may be still further simplified by taking the difference between parallel lines, or subtracting each non-effective wind, or each one that is less than its opposite from that opposite, and retaining only the remainder; thus, Fig 4 contains all the effective lines of Fig. 3, and yet by a great saving of labour gives the direction and length of resultant.

The resultant may also be found by calculation; but for the method of doing so we refer to Sir W. Snow Harris's 'Report on the Working of Whewell's and Osler's Anemometers, presented to the British Association for 1844,' and also to the 'Reports of the Meteorological Observatory at Greenwich. The working of Dr. Robinson's Anemometer at the Kew Observatory also presents some points of interest, which will be noticed under ANEMOMETER. We may also refer to Sir John Herschel's able article on METEOROLOGY, recently published in the new edition of the *Encyclopædia Britannica*.

AERONAUTICS. }
AEROSTATICS. } [BALLOON.]
AEROSTATION. }

ÆSTHETICS (*Æsthetik*) is the designation given by German writers to a branch of philosophical inquiry, the object of which is a philosophical theory of the beautiful, or, more definitely expressed, a philosophy of poetry and the fine arts, and which has by them been raised to the rank of a separate science. The word *Æsthetik* is derived from the Greek verb *αἰσθάνομαι I feel*, or *I am sensible*, and was first used as a scientific term by Alexander Baumgarten, a disciple of Christian Wolf, who in his 'Æsthetica' (Frankfort, 1750-1758, 2 vols. 8vo.) considered beauty as a given property of objects, of which we are "becoming sensible." We perceive beauty, says Baumgarten, wherever we meet with perfection manifested in reality, and a thing is perfect if it is adequate to its notion: beauty, accordingly, is the perfectness of an object manifested in its appearance. The impulse to a deeper research into the essence of beauty was given by Winkelmann, who, without embodying his views in a regular system, developed them chiefly in reviewing and appreciating the remains of ancient sculpture. He adopted neither Baumgarten's "adequateness of an object to its notion," nor the material principle of pleasing the senses, which had been proposed in various times by other authors, and more elaborately evolved by Edmund Burke as the criterion of beauty; but considered the idea of beauty as dwelling in the divine mind, and as passing over from that source into individual objects. Kant denied the possibility of a strict science of beauty, inasmuch as beauty, according to him, is not a property of objects, but has its origin in the disposition of our mental faculties. We presuppose, says he, that some notion is contained in the apparent object, though we are unable abstractedly to express that notion; we assume that a tendency towards some purpose has presided over the formation of the manifold variety displayed before us, though we cannot precisely define that purpose,—and this supposition or assumption forms the basis of our perception of beauty. Schelling's view of beauty and art it is difficult to state concisely. His 'System of Transcendental Idealism,' establishes the principle, that mind and nature, or conscious and unconscious existence, are primarily identical; that the laws discoverable in nature must accordingly be traceable to the laws of consciousness, whilst, *vice versâ*, the laws of consciousness must admit of being recognised as being likewise the laws of nature: in the divine mind both exist in absolute identity. The artist is to produce in his mind an intellectual intuition analogous to this identity, and the expression which he gives to the identity thus arrived at, is the work of art. This theory was to some extent opposed by one of his most eminent scholars, Heydenreich, who regarded the recognition of beauty or taste, as dependent on an original disposition or condition of the mind, which, elevated to a science, might educe canons of taste, at least so far as related to the fitness of objects for giving pleasure or displeasure, or as objects generally or necessarily considered as pleasing; and which might therefore be properly called æsthetical laws. Beauty, according to Schelling, is that manifestation of the principle of art where the infinite appears contained in or represented by the finite, or where, in the very object, the difference between the conscious and the unconscious (mind and nature) is annulled.

But this formal definition of beauty, an objectiveness without the representation of the object, was insufficient to satisfy the growing desire for a more living and actual notion of the beautiful than that which Kant seemed to recognise. The widening of the domain of art through the exertions of men of genius made this want constantly more felt. Göthe, Schiller, Lessing, Heinse, and others, partly through their poetical works, and partly through their discussions of the principles of poetry and art, gave a wider extent and a more genial feeling to the science, as it is called. The two Schlegels (but especially Friedrich Schlegel, in his 'Philosophy of Life,' lecture xii. and in his various papers on Art, first began to form these views into a system, and they were followed by Solger, Trahndorff, and Lommatsch, who published 'Die Wissenschaft des Ideals, oder der Lehre vom Schönen,' at Berlin in 1835. Hegel's views as to æsthetics were first published, after his death, by Hotho, in 1835-1838, and they are distinguished by the vast and varied richness of his illustrations, whilst they possess in full measure his obscurity of expression. Hegel considers the Beautiful as a representation of the Absolute, and indeed, as that which has only philosophy and religion above it. Hegel's 'Æsthetik,' published from his lectures by Hotho (Werke, b. 10), is divided into three parts:—

1. The Idea of the Beautiful, or the Ideal.
2. The development of the Ideal in the peculiar forms of the Beautiful in the Fine Arts—Classical and Romantic Art.
3. The system of the individual Arts; concluding with Poetry, classical and romantic.

Hegel says, "It is an error to suppose that the Beautiful—because it is beautiful—is an idea not to be seized and apprehended, but is to remain, therefore, for the thought an intangible object." The Beautiful is only another name for the True (and Schiller, in like manner, wished it were possible "to banish the notion, and even the very word Beauty from use, and, as is right, put Truth, in its complete sense, in its place.")

The finite spirit feels an irrepressible desire for the true, and laboriously attains thereby to its infinity. This truth of the finite spirit is the absolute.

This is the basis—for the beautiful in Art, is neither the logical idea, the absolute notion as it is developed in the pure element of thought, nor the merely natural idea, but it belongs to the internal or spiritual dominion, without, however, being fixed by the perceptions and acts of the finite spirit.

Forms divide themselves into three classes: 1. A direct and, therefore, a sensible (sinnlichen) perception, a knowledge of the form and figure of the thing itself as conveyed objectively by the senses; 2. A represented consciousness; and, 3. The free and absolute creation of the mind itself.

If we would rightly understand the place which Art occupies in the collective domain of natural and spiritual or intellectual life, we must consider the entire purport of our being; when we at once find that not alone must the physical and social wants be satisfied, and the religious feeling which is implanted in man, find its proper object; but that the intellectual faculties—the totality of knowledge and perception, in short, which all are conscious of in themselves—must find their adequate occupation. And within this totality comes the desire for the fulfilment of its perception in Form.

As the ideal of the Beautiful in Art, Hegel believes that he has established that there are—First, an abstract form or inner notion (Inhalt): secondly, the expression, or the reality of this significance: and thirdly, that both these must be so interpenetrated by each other, that the outward form becomes only a representation of the inner; and is otherwise non-existent, except as a necessary clothing of the abstract form, idea, or conception (Inhalt). For this, he says, which we call the Inhalt, is the object itself in the simplest form, even when brought back by surrounding definitions in opposition to actual representation. This simple conception, this thesis, as we may say, which forms the basis of all actual representation, is the abstract; as the actual representation, the full development on the contrary, is the concrete.

Thus, as Müller expresses it ('Handbuch der Arch. der Kunst') "Art is a representation, or activity, by means of which, something internal or spiritual is revealed to sense. Its only object is to represent, and it is distinguished by its being satisfied therewith from all practical activities which are directed to some particular purpose of active life." Under the influence of Hegel's ideas many works of considerable merit have appeared, such as 'Neue Vorschule der Æsthetik,' published at Halle in 1837 (which is modelled on the form of J. P. Richter's work of the same title), and Vischer's work, 'Ueber das Erhabene und Komische.' Darmstadt, 1837.

The above meagre definitions may serve in some measure to characterise the points from which some of the principal German philosophers have started in their respective systems of æsthetics. We think it not irrelevant to remind our readers that it is almost impossible to condense within a few words what it would require a dissertation fully to explain and to discuss; and also, that the opinions of any philosopher reported in a foreign language are always apt to appear to disadvantage, but more particularly so when the language in which they were originally expressed affords such wonderful facilities for the utterance of speculative thought as the German.

Many German writers have, with greater or less independence, followed the principles laid down by Baumgarten, Kant, Schelling, or Hegel. They commonly divide their systems into a general part, or a discussion of the essence of beauty and art, and a special one, or an inquiry into the peculiar character and predominant principles of the several branches of poetry on the one hand, and the fine arts (chiefly sculpture, architecture, painting, and music) on the other.

In a wider and more general meaning, æsthetical is often used in opposition to logical, as expressing the feeling of pleasure given by viewing an object, without reference to its utility.

ÆTHERS. [ETHERS.]

AFFEERERS. [LEET.]

AFFETTUO'SO (Ital. *affectionate*), in Music, signifies a tender, expressive style; and slowness is invariably implied. In regard to movement it may be considered as equal in degree to larghetto.

AFFIDA'VIT is a statement of facts in writing, on oath. The word is the perfect tense of the barbarous Latin word *affido*, to pledge faith to, and is taken from the old Latin form of a declaration on oath, which commenced thus: *"Affidavit J. S.,"* "J. S. hath sworn," &c. By the practice of our tribunals, affidavits are necessary in many cases, in order to bring facts under the cognisance of courts of justice. All evidence of facts must be given on oath, or affirmation, either by oral testimony or by affidavit. Where evidence is to be acted upon by juries, it is given as oral testimony; where it is to inform a court or judge, it is often put in the form of an affidavit.

An affidavit is usually made as follows: If made in a cause, the name of the court in which the cause is pending, and the names of the plaintiff and defendant, are written at the head of the paper. The name, description, and residence of the deponent, or person making the affidavit, are written at length, and the individual who makes the affidavit signs his name at the foot of it. The paper is then read over to him, and he is requested to swear that the contents of the paper are true. And lastly, the *jurat* (a term derived from the Latin word *juratum*, 'sworn') expressing the officer [judge, commissioner, magistrate, or other person] before whom, and where, and when, the affidavit is made, is signed by that officer. If the affidavit be sworn in open court, that circumstance is mentioned in the *jurat*, and no officer is named.

The forms of affidavit are generally regulated by the rules of the particular courts in which they are to be used, great strictness being in all cases required in their preparation.

AFFINITY (from the Latin *adfinitas*) means a relationship by marriage. The husband and wife being legally considered as one person, those who are related to the one by blood are related to the other in the same degree by *affinity*. This relationship being the result of a lawful marriage, the persons between whom it exists are said to be related *in law*; the father or brother of a man's wife being called his *father-in-law* or *brother-in-law*. Affinity is of importance in one respect, that by law it may be an impediment to marriage, for persons related by affinity are forbidden to marry within the same degrees as persons related by blood. This rule which excludes from marriage those who are within certain degrees of affinity is supposed to be founded on the Mosaic law. The degrees of relationship, both of consanguinity and affinity, within which marriages are prohibited, are contained in Archbishop Parker's 'Table of Kindred and Affinity, wherein whomsoever are related are forbidden in Scripture and our laws to marry together.' Parker, of his own authority, ordered this Table to be printed and set up in the churches of his province of Canterbury. The Constitution and Canons Ecclesiastical, which were made in the reign of James I., 1603, confirmed Parker's Table, which thus became part of the marriage law so far as that law is administered by the Ecclesiastical Courts. Marriages within the prohibited degrees could formerly only be annulled by the Ecclesiastical Courts, and only during the life of the husband and wife. The 5 & 6 Wm. IV. c. 54 (1835) however declares that all marriages celebrated *before* the passing of that Act between persons within the prohibited degrees of affinity shall not be annulled for that cause by any sentence of the Ecclesiastical Court; but that all marriages which shall hereafter be celebrated between persons within the prohibited degrees of consanguinity or affinity shall be absolutely null and void. This Act does not define what are the prohibited degrees, and this part of the enactment must be interpreted by a reference to Parker's Table, and the canons, if the question arises before courts spiritual; and by statute or judicial decisions, if it arise in the civil courts. The principal statute is the 25 Hen. VIII. c. 32. (Black. 'Comm.,' Mr. Kerr's ed. vol. i. p. 452.)

There are certain cases of prohibition, such as the prohibition against a man marrying his deceased wife's sister, which are considered by many persons to rest on no good reasons.

The general rules on this subject are the same in Scotland as in England; but the 5 & 6 Wm. IV. c. 54, does not extend to Scotland.

The distinction between affinity and consanguinity is derived from the Roman law. The kinsfolk (*cognati*) of the husband and wife became respectively the *adfines* of the wife and husband. We have borrowed the words affinity and consanguinity from the Roman law, but we have no term corresponding to *adfines*. The Romans did not reckon degrees of *adfinitas* as they did of consanguinity (*cognatio*); but they had terms to express the various kinds of *adfinitas*, as *socer*, father-in-law; *socrus*, mother-in-law.

AFFINITY IN CHEMISTRY. [CHEMICAL AFFINITY.]

AFFIRMATION, in Law, is the solemn asseveration made by Quakers, Moravians, and Separatists, in cases where an oath is required from others. This indulgence was first introduced by 7 & 8 Wm. III., c. 34, which enacts that the solemn affirmation of Quakers in courts of justice shall have the same effect as an oath taken in the usual form. The provisions of this statute were extended by 8 Geo. I. c. 6, and 22 Geo. II. c. 46, s. 36; but in all there is a clause restraining Quakers from giving evidence on their affirmation in criminal cases. This exception, which Lord Mansfield called "a strong prejudice in the minds of the great men who introduced the original statute" (Cowper's 'Reports,' p. 390), was removed by 9 Geo. IV. c. 32. Quakers, Moravians, and Separatists (3 & 4 Wm. IV. cc. 49, 82), may now give evidence in all cases, upon their solemn affirmation. The Act 1 & 2 Vict. c. 77, allows the same privilege to persons who have been at any time Quakers, Moravians, or Separatists, and have ceased to be such, but still have conscientious objections to the taking of an oath. Now, however, *every person* who has conscientious objections to taking an oath, may be permitted to make a solemn affirmation in lieu thereof, the effect of which is the same as if the testimony were given on oath. (Common Law Procedure Act, 1854.)

In the session of Parliament of 1833, a question arose respecting the sufficiency of the affirmation of a Quaker, instead of the customary oaths, on his taking his seat in the House of Commons. The subject was referred to a committee, on whose report the House resolved that the affirmation was admissible. This was more than once attempted to be made a precedent for permitting a Jew to take the oaths, without adding the words "on the true faith of a Christian." Ultimately the statute 21 & 22 Vict. c. 49, was passed, to enable either House of Parliament to dispense with these words.

AF'FIX, a term in grammar, to which the name of *suffix* also is sometimes given. It signifies a *syllable* attached to the *end* of a word by which the form and signification of the word are altered. This will be best explained by some examples from our own language. Thus in the words *wealth-y*, *weight-y*, *bulk-y*, and in *god-ly*, *odd-ly*, &c., the syllables *y* and *ly* are the affixes, which qualify the meanings of the words to which they are attached, and fit them for a new and different use; as 'This man loves *wealth*;' 'That is a *wealthy* merchant.' Verbs are in this way made from adjectives, as from the adjectives *sharp*, *quick*, *thick*, we have *sharpen*, *quicken*, *thicken* respectively; and adjectives and adverbs from nouns, as in the examples just given. The *'s*, which marks our possessive case, is an affix, having originally been a distinct syllable, as we see from our old books in such expressions as

Goddes will; *mannes* duty. Some persons are of opinion that this *'s* has arisen from the possessive pronoun *his*, as in such a phrase *God his will, man his duty;* but we are of opinion that this final *'s* is to be referred to the German and Anglo-Saxon genitive termination *es.* When we hear people vulgarly say *hisn, hern*, for *his, her*, the *n* is the remnant of the syllable *en*, which in these instances marks a kind of pronominal adjective, akin to the genitive or possessive case; as we may still observe in the German forms *dessen*, &c.

In the Latin and Greek, and many other languages, there is the same system of affixes of which we have given examples in the words *weighty, bulky;* and in these languages the different cases of nouns, and adjectives, and the different tenses and persons of the verbs, are also formed by affixes. Thus the nominatives *Pindaru-s, Homeru-s, Liviu-s, Antoniu-s*, are the true Roman forms of these names, which, in the accusative, form *Pindaru-m, Homeru-m*, &c., respectively, and so on in the other cases. With the English it is the common practice to shorten all these words to Pindar, Homer, Livy, Antony; and yet we are not consistent in this practice, for we say *Tibullus, Æmilius*, &c., keeping, in these instances, the genuine form just as it is in the language to which these names belong. The irregularity depends upon the greater or less familiarity of the names. With the French, the changes are still more violent.

AFRICAN ASSOCIATION, a society which was formed in London, in the year 1788, with the design of encouraging men of enterprise to explore the interior of Africa; of acquiring by their means a knowledge of the character of the native inhabitants; and of being enabled to introduce among them the arts of civilisation. The association, during the period of its labours as a distinct body, commissioned for their objects several travellers, whose zeal and ability have furnished the best evidence of the correctness of the association's choice.

The first person thus commissioned was John Ledyard. While preparing himself for his undertaking, in August 1788, Mr. Ledyard was seized with a bilious fever, and died at Cairo. His successor was Mr. Lucas.

The next person engaged by the association was Major Houghton. He arrived at the mouth of the river Gambia in November 1790, and after various adventures attended with severe privations, died at Jarra, in September 1791, not without strong suspicions of having been murdered. Without being discouraged by these repeated disappointments, the association sought for some other person to prosecute their plans, and were fortunate in meeting with Mungo Park, who sailed in May 1795. The second journey of this adventurous traveller, in 1804, was undertaken at the expense of Government.

The association subsequently engaged Mr. Hornemann, a German; Mr. Nicholls; and a young German named Roentzen. The last missionary of the association was John Lewis Burckhardt. He sailed for Aleppo in March 1809, and died at Cairo in 1817.

Repeated failures appear at length to have discouraged the association from engaging other missionaries. A great deal of information, connected with the geography of Africa, was collected by them from various sources during the period of their active labours; and this information was communicated to the public in the occasional printed reports of their proceedings. The association has merged in the Royal Geographical Society, into which body its few remaining members were admitted in 1831.

(*Proceedings of the Association*, from 1794 to 1805; Leyden's *History of Voyages and Discoveries in Africa*, edited by H. Murray; and *Journal of the London Geogr. Soc.* vol. i. p. 257.)

AFRICAN COMPANY, a regulated trading company, established by the act 23 Geo. II. c. 31 (1754). In the course of time it happened that the whole expense of the Company came to be defrayed by the public, and for this reason the charter of its incorporation was recalled by Parliament in 1821 (1 & 2 Geo. IV. c. 28). The possessions of the Company on the west coast of Africa were by this act annexed to and made dependencies upon the colony of Sierra Leone.

AFRICAN INSTITUTION, a society established in London, in April, 1807, the declared objects of which were to collect accurate information respecting the African continent and its inhabitants, to cultivate friendly relations with the African people, and to introduce among them the arts of civilisation. As an important instrument for promoting these objects, the members of the institution were invited to devote their individual attention and united influence to obtain the enforcement of the law, then recently passed, for abolishing the African slave trade, and to expose all attempts to evade its provisions. In this part of its functions the vigilance of the institution was unceasing; and the exertions of the directors were successfully applied towards obtaining an Act of Parliament declaring the trading in slaves to be felony.

The British and Foreign Antislavery Society, and the Church, the London, and the Wesleyan Missionary Societies, which have each established missions and schools in various parts of Africa, were established at various periods, and made the civilisation of the Africans one of the chief objects of their organisation. In 1839, was founded in London the Society for the Extinction of the Slave Trade and the Civilisation of Africa, whose first public meeting was presided over by Prince Albert in June 1840. The object of the society was to seek and make known the best means of civilising Africa, but they did not undertake to send out missions, though it was on its recommendation that the unfortunate expedition to explore the Niger was undertaken in 1841. One of its principal members was Sir T. F. Buxton; and its organ 'The Friend of Africa,' published monthly, which first appeared in January 1841, placed before the world several plans for the amelioration of the negro.

In the United States of America, likewise, several societies have been established for similar purposes. In 1774, Rush and Pemberton formed a society in Pennsylvania, for the abolition of slavery, and to relieve helpless and oppressed negroes; and which, after some interruption, was re-established in 1787, under the Presidency of Franklin, with renewed vigour; and another was formed with the same object, in 1785, by President Jay. In 1791, an association was formed for transporting the slaves to Sierra Leone; but their right to do this was resisted by the English government, and it resulted eventually in the establishment of Liberia. Whatever might have been the motives of the founders, it is certain that the effect has not been to lessen slavery or its ill consequences within the limits of the United States, but rather to perpetuate it, by giving opportunities of getting rid of sickly, turbulent, or dangerous individuals; and nothing has been done to decrease or ameliorate the state of slavery within the home dominions of the States.

AFTER-MATH is the grass which grows after the hay has been made; it is also called latter-math, rowen, or rowett, and when left long on the ground it is called fogg in some places. Where the land is rich and hay valuable, the after-math is often mown and made into hay. This hay is inferior in value and nourishment to the first crop, which contains the flower-stalks of the grass. It is not good for horses, especially those which are driven fast and work hard; it is thought injurious to their wind. Cows and sheep are fond of it, and with them it is not liable to the same objection. Whether it be more profitable to cut a second crop of hay, or to feed off the after-math, must depend on circumstances and situations. Unless the meadows can be irrigated, or well manured, taking off two crops of hay in one year exhausts them, and is apt to produce moss, which the tread of sheep and cattle prevents.

There is a practice with some farmers to leave the after-math on the ground from hay-making time till the next spring; this is then called *fogg;* and the young grass, springing up through the old, makes it palatable to young cattle. Arthur Young mentions this practice with some commendation, as a resource in spring; but it does not accord with a well-regulated system of husbandry, in which all food should, if possible, be given in its most perfect state. The fogg, half rotten by a wet winter, cannot be wholesome food; besides, slugs and various insects breed in it. The after-math should be fed off clean before winter. A good farmer should have hay, straw, and roots sufficient for his stock. Swedish turnips, mangel wurzel, carrots, &c., can be stored in winter, and strewed upon the pastures in spring, by which the stock will be better fed, and the land improved.

AGA, the name of a dignity, and also an epithet of respect, among the Turks. The word is said to be of Tatarian origin, and signifies literally a great man, a lord, or a commander. In Turkey, the Aga of the janissaries, while that corps subsisted, was their commanding officer or colonel, whose place was one of high authority and dignity in the state. There is also the spahilar-aga, that is, the colonel of the spahis, or cavalry; the topd-schilar-aga, or commander of the artillery; and the kisslar-aga, or guardian of the harem. Aga is likewise the common epithet of civility used in addressing or speaking of the eunuchs employed in the seraglio; and their chief is distinguished by the title of Capi Aga. The Capi Aga, or Capi Agassi, as he is often called, is one of the principal officers of the court of Constantinople.

AGAPÆ (ἀγάπαι), the plural of the Greek ἀγάπη, which signifies love, or charity. In the history of the Christian church, the agapæ were those meetings of the early believers, where they sat and ate, at a common table, of food which had been provided by the voluntary contributions of the members of the society, the entertainment being concluded with the holy kiss. These meetings, which were usually held in the same house or apartment in which they assembled for divine worship, are mentioned in the 12th verse of the epistle of Jude, where it is said of certain unworthy brethren "these are spots in your feasts of charity." It is probable also that St. Paul alludes to them in 1 Cor. xi. 20, where his language would seem to imply that the agapæ were connected with the sacrament of the Lord's Supper. They arose from that charity towards the poorer brethren which was so strongly inculcated upon the first followers of Christianity, both by the religion they professed and the circumstances in which they were placed. Even in the days of the apostles, however, these meetings had been occasionally perverted from the purpose of their institution, and in time they gave occasion of scandal to the enemies of the faith. The reader may find an account of the accusations of which they were made the groundwork by some of the pagan writers in the 16th chapter of Gibbon's History. They seem to have been generally celebrated for several centuries. Ecclesiastical writers mention three kinds of them: first, those which took place at marriages, called the nuptial or connubial agapæ, to which the bishop or pastor was usually invited; second, the anniversary, or, as they were called, natal agapæ, which were held in the churches on the festivals of the martyrs; and, third, the funeral agapæ, at the interments of members of the congregation. The celebration of the love-feasts in the churches was at length expressly forbidden by the 25th canon of the council of Laodicea, in A.D. 364; although the enactment for a considerable time was not quite effectual, since we find it repeatedly renewed by subsequent councils. Indeed the practice under improved regulations appears to have been continued in certain circumstances by the heads of the church. In the 6th century, as we are informed by Bede, Pope Gregory, in his instructions to Austin when he sent him to Britain to convert the Saxons, advised him to allow the new converts to feast together on saints' days, and the anniversaries of the dedication of the churches, not in the churches themselves, but in sheds fashioned with green boughs close by them, to the glory, he says, of God, as they had formerly done to the honour of the devil. A great deal of ingenious speculation has been expended in the attempt to discover traces of the Christian agapæ, both among the Jews and pagans before the institution of our religion, and in the latter times of the Church. But the only thing in modern times corresponding to the primitive love-feasts, is the practice which has been introduced under the same name by certain sects, especially the Moravians and the Sandemanians. The Methodists also have 'love-feasts,' but they bear very little resemblance to the ancient agapæ. (Augusti's *Antiquities of the Christian Church*, Ward; Giesler's *Church History;* Neander.)

AGATHOTES CHIRAYTA. [CHIRAYTA.]

AGE. In legal acceptation, a person is said to be 'of age' when he has passed that period of life at which he is supposed to have acquired sufficient discretion to enable him to perform acts and enter into contracts, of which, before that period has arrived, he is presumed to be incapable, by reason of immaturity of understanding. The common law appoints certain specific times in the life of a man or woman before either is permitted to form contracts or incur obligations. Thus a male of the age of twelve years may take the oath of allegiance; and at fourteen, which for many purposes is considered the age of discretion, a person of either sex may choose a guardian, and be a witness, though children under twelve are frequently permitted to give evidence, after it has been ascertained by examination that they understand the nature of an oath. Formerly a female of twelve or a male of fourteen years, might validly bequeath personal estate; now by 1 Vict. c. 26, no will made by any person in England under the age of twenty-one years is valid. The law of Scotland in this respect resembles the former law of England. A person cannot act as executor till he is twenty-one.

A woman may consent to marriage at twelve, and a man at fourteen years of age; though parties under the age of twenty-one years cannot marry without the consent of their parents or guardians. [MARRIAGE.] The age of twenty-one years is, for most civil purposes in this country, the full age both of a man and woman, at which period they may enter into possession of their real and personal estates, may manage and dispose of them at their discretion, and make contracts and engagements. All persons under the age of twenty-one are legally called infants. A man cannot be ordained a priest till twenty-four, nor be a bishop till thirty years of age. A man cannot be a member of the House of Commons before the age of twenty-one. In the United States of America, a senator must not be under thirty, and to be eligible to a seat in the House of Representatives he must have attained the age of twenty-five. In France the age of twenty-five was formerly required in both electors and elected.

With respect to crimes, the law of England regards the age of fourteen years as the age at which a person is competent to distinguish between right and wrong. Under the age of seven years a child is not punishable for an offence; but above that age, and under the age of fourteen years, if it clearly appears that a child is conscious of the nature of the crime which he commits, he may be tried and punished for it. See Foster's 'Crown Cases,' p. 72, where a boy of nine was found guilty and executed for murder.

By 9 Geo. IV. c. 31, ss. 17, 18, and 4 & 5 Vict. c. 56, s. 3, carnal knowledge of a female under ten years of age is a felony punishable by transportation for life; the carnal knowledge of a female above ten and under twelve is a misdemeanor punishable by imprisonment and hard labour; as is also now an attempt to commit the offence, 14 & 15 Vict. c. 100, s. 9.

By 9 Geo. IV. c. 31, s. 20, the abduction of a girl under sixteen is punishable by fine or imprisonment; and by 12 & 13 Vict. c. 76, s. 1, procuring the defilement of a girl under the age of twenty-one, is a misdemeanor punishable by two years' imprisonment with hard labour. Apprentices and servants are protected against ill-usage from the master or mistress, by 14 Vict. c. 11, s. 1; and wives against the brutality of husbands, and children against that of parents, by 16 & 17 Vict. c. 30. (Blackstone's 'Comm.,' Mr. Kerr's ed., v. iv., pp. 61, 235, 241, 245.)

The Romans made three periods of age with reference to legal capacity: 1. Infantia, or the period from birth to the completion of the seventh year; 2. from the termination of infantia to the attainment of puberty, when persons were called Puberes; 3. from the attainment of puberty to the twenty-fifth year, during which time males were called Adolescentes, or Minores. From the attainment of the twenty-fifth year they were called Majores. An Infans could do no legal act. A person under the age of puberty could do the necessary legal acts in respect of his property with the sanction (*auctoritas*) of his tutor, who was the guardian of his property. It was somewhat unsettled what was the age at which a male attained puberty, but the best opinions fixed it at fourteen. A woman attained puberty at the age of twelve. Males who were puberes could manage their property, contract marriage, and make a will. Roman women of all ages were under some legal incapacities. Male persons between the age of puberty and twenty-five were protected to a certain extent in their dealings by a Lex Prætoria, and the rules of the Prætorian Edict, which were founded upon it. Under the Emperor Marcus Aurelius, all persons under twenty-five were required to have a curator, whose functions and powers were somewhat similar to those of the tutor up to the age of puberty.

(Savigny, *Von dem Schutz der Minderjährigen*, *Zeitschrift für die Geschichtliche Rechtswissenschaft*, vol. x., and *System des Heut. Röm. Rechts*, iii. 21, &c.)

AGENT (from the French *Agent*, and that from the Latin *Agens*). An agent is a person authorised by another to do acts for him or make engagements in his name; and the person who authorises him is called the *principal*.

An agent cannot be appointed to bind his principal by deed otherwise than by deed; nor can an agent be appointed by a corporation aggregate (unless for certain ordinary and inferior purposes) otherwise than by deed: and for certain purposes specified in the first, second, and third sections of the Statute of Frauds, the authority of the agent must be in writing. In all other cases no particular form is necessary: in commercial affairs agents are usually commissioned by a letter of orders, or by a retainer, but a verbal appointment is sufficient; and the mere fact of one person's being employed to do any business for another creates between the parties the relation of principal and agent.

An agent's authority (unless it is an authority joined with an interest, such as a power of attorney granted as a security for a debt) may, in general, be revoked by the principal at any time. It ceases upon the death or bankruptcy of the principal.

There are many kinds of agents, such as bailiffs, factors, brokers, &c. This article contains the general principles of law, which are applicable to all.

The general rule is that a man may make any contract by an agent which he can make himself, and do any act with respect to his own property by an agent which he may do himself. Any person may be an agent who would be competent to do the act for himself.

When an agent's authority is limited, he must adhere strictly to his instructions. If instructed to sell, he must not barter; nor if instructed to sell at a certain price, is he authorised to take less.

When the agent's authority is not precisely determined, his duty is to act in conformity with what may reasonably be presumed to be the intentions of the principal. In the absence of all other means of ascertaining what these intentions are, he must act for his principal like a prudent man in the management of his own business. If he is authorised to sell, and no price is limited by his instructions, he must endeavour to obtain the best price for the goods. If there have been other transactions of the same nature between the parties, it is presumed that the principal intends that the same mode of dealing should be pursued, which in former cases he had prescribed or approved.

In mercantile transactions, when the agent has no particular instructions, he should follow the common usage of the business in which he is employed; and he will be justified in doing so, even though, under the particular circumstances, he might have acted otherwise to the advantage of his principal.

The general authority to act as agent includes all necessary or usual means of executing it. An agent is therefore authorised to do all such subordinate acts as are either requisite by law, in order to the due performance of the principal object of the instructions, or are necessary to effect it in the best and most convenient manner, or are usually incidental to it in the ordinary course of business. Thus it the duty of an agent employed in the receipt or despatch of goods, to take care that the custom-house duties are satisfied, and the proper entries made; and he is authorised in making advances, as well for such incidental charges, as for any other expense necessarily incurred for the preservation of the property.

The next duty of an agent is to exercise a proper degree of diligence and skill. If he does an act which is not warranted by his authority, either express or implied, or if he does an act within his authority, but with such gross negligence or unskilfulness that no benefit can accrue from it, the principal may reject what he has done, if he rejects it as soon as he is informed, and gives notice to his agent within a reasonable time. If an agent puts out his employer's money at interest without his authority, or if a factor, employed to purchase, deviates from his instructions in price, quality, or kind, the principal may disavow the transaction.

If the principal does not either expressly or impliedly adopt the agent's act, the hazard of it lies with the agent, even though he did it in good faith, and for the interest of his employer. Any profit that may accrue from it he must account for to his principal; and if loss ensues, he is bound to make it good to him. An agent is likewise answerable to his principal for all damage occasioned by his negligence or unskilfulness. His responsibility extends to the whole amount of the damage suffered by the principal, either by damage done to his own property, or by his being obliged to make reparation to others.

It does not however extend to such losses by fire, robbery, or otherwise, as are purely accidental, and happen by no default of his own.

If an agent's negligence is so gross, or his deviation from his authority so great, as to amount to a breach of duty, that is, to a breach of the contract which the law, as we have seen, implies between them, the agent is liable to an action.

An agent must keep a regular account of his dealings on behalf of his principal, communicate the results from time to time, and account honestly when called upon.

An agent is not in general accountable for money until he has actually received it, unless he has by improper credit, or by other misconduct, occasioned a delay of payment. But an agent acting under a commission *Del credere*, that is, one who has undertaken to be surety to his principal for the solvency of the persons whom he deals with, is, in their default, accountable for the debt. If an agent has received money on behalf of his principal, he is bound to take care of it; and if any loss is occasioned by the fraud or failure of third persons, he will, unless his conduct be warranted by his instructions, or the usage of trade, be bound to make it good.

The agent must account for any interest which has been made upon the balance in his hands; and for all profit which he may have derived by dealing or speculating with the effects of his principal.

It is the duty of an agent to apprise his principal, with all convenient expedition, of all material acts done or contracts concluded by him.

The conduct of an agent, confidentially intrusted and relied on for counsel and direction—as an attorney, for instance—is liable to a stricter investigation, if he in any way acts improperly.

We now consider what are the duties of the principal to his agent; or what are the rights of an agent against his principal.

An agent is entitled to his commission; that is, a remuneration in return for his services. The amount of commission is usually determined by agreement; sometimes it is regulated by the usage of trade; and in some few cases it is limited by Act of Parliament, but the principle on which this legislation was founded has long been considered unsound.

An agent may forfeit his right to commission by misconduct: as, if he keeps no account; if he makes himself an adverse party to his principal; or if, in consequence of his negligence or unskilfulness, no benefit accrues to the principal from the services performed.

An agent is also entitled to be reimbursed all such advances made on behalf of his principal, as are justified by his authority, whether expressed or implied, or subsequently sanctioned by his principal. And cases may sometimes occur of urgent danger, when there are no means of referring for instructions, in which an agent is justified in making advances without particular directions. If, on account of the lateness of the season, or other good cause, he insures the cargo without orders, he is entitled to charge his principal with the premium, and in such case the assent of the principal would be inferred from very slight circumstances.

An agent has a lien upon the property of his principal; that is, a right to retain possession of it till his demand is satisfied. [LIEN.]

It remains to explain the consequences of the relation of principal and agent, as between the parties and third persons: and, first, as between the principal and third persons; and, secondly, as between the agents and third persons.

It is a general rule that the act of the agent is to be considered as the act of the principal. A bargain or agreement entered into by an agent therefore binds his principal, whether it tends to his benefit or his disadvantage: and, in order to have this effect, it is not necessary that it should be within the agent's real authority, either express or implied, provided it be within what may be called his *apparent authority*—that is, provided it is such as the person dealing with the agent might reasonably presume to be within his authority. An authority may be presumed from the principal's having previously authorised or sanctioned dealings of the same nature. Thus, if a person has been in the habit of employing another to do any act,—as, for instance, to draw or indorse bills,—he will be answerable for any subsequent acts of the same nature,—at least, until it is known, or may reasonably be presumed, that the authority which he had given has ceased. An authority may likewise be presumed from the conduct of the principal, with reference to the subject-matter of the transaction in question. For if a person authorises another to assume the apparent right of engaging in any transactions, the apparent authority must, as far as regards the rights of third persons, be considered as the real authority. Thus, a broker employed to purchase has no authority to sell; and if he does, his employer may (unless the sale was in open market) reclaim the goods so sold, into whatever hands they may have come. But if the principal has permitted the broker to assume the apparent right of selling the goods, he will be bound by a sale so apparently authorised.

Upon the same principle, when a *general* agent is employed,—that is, an agent authorised to transact all his employer's business of a particular kind, as to buy and sell certain wares, or to negociate certain contracts,—he must be presumed to have all the authority usually exercised by agents of the same kind in the ordinary course of their employment: and though the principal may have limited his real authority by express instructions, yet he will not thereby be discharged from obligations incurred in the ordinary course of trade towards persons who have dealt with the agent without any knowledge of such limitation. Thus where an agent purchases goods on credit, the seller may come on the principal for payment: and this right cannot be affected by any private agreement between the principal and agent, by which the agent may have stipulated to be liable to the seller.

Although the agent is, in all these cases, ultimately answerable to his employer for any damage that may follow from his having entered into an engagement not within his authority; yet the principal is, in the first instance, bound to keep an engagement so entered into by his agent upon a reasonable presumption of authority.

But in the case of a *special* agent (that is, of a person appointed merely to do certain particular acts), as no presumption of authority can arise from usage of trade, the principal will not be bound by any act not within the real authority of the agent; those who deal with the agent must ascertain what his authority actually is.

The agreement made by an agent, and all his dealings in connection with it, provided they are within his real or apparent authority, are binding on the principal. The representations made by an agent, at the time of entering into an agreement, (if they constitute a part of such agreement, or are in any way the foundation of or inducement to it), and, in many cases, even the admissions of an agent as to anything directly within the course of his employment, will have the same effect as if such representations or admissions had been made by the principal himself. If notice of any fact is given, or if goods are delivered to an agent, it will be considered as notice or delivery to the principal. And in general, payment to an agent has the same effect as if it had been made to the principal. But such payment must be warranted by the apparent authority of his agent. If money is due on a written security, as long as the security remains in the hands of an agent it is to be presumed that he is authorised to receive the money: but if he has not the security in his possession, the debtor will be liable, in case the agent should not account for it to his principal, to pay it over again.

If the principal gives notice to the buyer not to pay the money to the factor with whom he made the bargain, he will in general not be justified in doing so; but if the factor had a lien upon the goods for his general balance, he has a right to require the buyer to pay him instead of his principal; and such payment, notwithstanding any notice given by the principal, will be a discharge of the debt.

A principal is in general liable for all damage occasioned to third persons by the negligence or unskilfulness of his agent, when he acts within the scope of his employment; and for any misconduct or fraud committed by him, if it be either at his express command or within the limits of his implied authority. From this liability however persons are exempted who, though they appear in some degree in the character of principals, yet have no power in the appointment of those who act under them. Thus, the postmasters-general, and persons at the head of other public offices, have been held not to be liable for the conduct of their inferior officers. The owners and masters of vessels are also by statute released from liability to third persons from the negligence or unskilfulness of the pilots by whom the vsesels are navigated into port.

It remains to state what are the effects of the relation of principal and agent, as between the agent and third persons.

An agent is not in general personally responsible on any contract entered into by him on behalf of his principal; but there are several exceptions to this rule. For if an agent has so far exceeded his authority that his principal is not bound by his act, the agent is liable. And an agent is also liable when the contract was made with him not as agent. If in any contract made on behalf of his principal, the agent binds himself, or if the circumstances of the transaction are such that the credit was originally given to him, and not to the principal (whether such principal were known at the time or not), the agent will be liable, in the first instance, to the persons with whom he has dealt.

When an agent acts in his own name, and gives no notice of his being employed in behalf of another person, he is to be considered as the principal, and the persons who have dealt with him have the same rights against him as if he actually were so. In an action by the principal on demand arising from such transactions, they may set off a debt due from the agent himself; which they could not have done, if they had known that he acted only as an agent. And if he afterwards discloses his principal, he is not discharged from his liability; those with whom he has dealt may, at their option, either sue him on his personal contract, or the principal upon the contract of his agent.

An agent is responsible to third persons for any *wrongful* acts, whether done by the authority of his principal or not; and in most instances the person injured may seek compensation either from the principal or the agent, at his option.

An agent cannot delegate his authority to another, but he may employ other persons under him to perform his own engagements, and the original agent is responsible to his principal as well for the conduct of such sub-agents as for his own: but with respect to damage sustained by third persons from the wrongful acts of such sub-agents, the damages must be recovered either from the person who did the injury, or from the principal, for whom the act was done. The original agent is responsible to third persons only for his own acts, and such as are done by his command.

If an agent who is intrusted with money or valuable security, with written directions to apply the same in any particular manner, converts it to his own use; or if an agent who is intrusted with any chattel, valuable security, or power of attorney for the transfer of stock, either for safe custody or for any special purpose, without authority sells or pledges, or in any manner converts the same to his own use, he is guilty of a misdemeanor punishable with fourteen years' transportation, or to fine and imprisonment at the discretion of the court. But this does not prevent his disposing of so much of any securities or effects on which he has a lien or demand, as may be requisite for the satisfaction thereof. It is also a misdemeanor, punishable in the same manner, if a factor or agent employed to sell, and intrusted with the goods, or the documents relating to them, pledges either the one or the other, as a security for any money borrowed or intended to be borrowed, provided such sum of money is greater than the amount which was at the time due to the agent from the principal, together with any acceptances of the agent on behalf of his principal. (7 & 8 Geo. IV. c. 29, s. 49, &c.)

The 5 & 6 Vict. c. 39, entitled "An Act to amend the law relating to advances *bonâ fide* made to agents entrusted with goods," facilitates the practice of making advances on the security of goods or documents to persons who are known to have possession of them as agents. Any agent who is in the possession of goods, or of the documents of title to them, is to be held in law as the owner, to the effect of giving "validity to any contract or agreement by way of pledge, lien, or security *bonâ fide* made by any person with such agent." The agent may receive back goods or documents which have been pledged for an advance, and may replace them with others; but the lender's lien is not to extend beyond the value at the time of the original deposit. The documents which are held to authorise the agent in disposing of property represented by them, and the transference of which is a sufficient security to the lender, are—"any bill of lading, India-warrant, dock-warrant, warehouse-keeper's certificate, warrant or order for the delivery of goods, or any other document used in the ordinary course of business as proof of the possession or control of goods, or authorising or purporting to authorise, either by indorsement or delivery, the possessor of such document to transfer or receive goods thereby represented." Any agent who is in possession of such documents in the mode in which the act mentions, is considered to be in possession of the goods, and all pledges of such documents are pledges of the goods. An advance of money on the delivery of the goods or documents, pursuant to a written agreement to make such delivery, is valid, although the delivery of the goods or documents do not take place till after the advance. A contract by the agent's clerk, or any person acting for him, is binding. An agent who, contrary to his instructions and for his own benefit, grants a fraudulent security, is liable to a very severe punishment. There are provisions in the Act for enabling the owner to redeem his goods while they remain unsold, on satisfying the person who holds them as a security; and for protecting the principal in the case of the agent's bankruptcy.

AGES OF THE WORLD. In the mythology of the Greek and Roman poets, the history of the world was divided into four ages, the golden, the silver, the brazen, and the iron; as, for instance, Hesiod in his poem entitled 'Works and Days,' and by Ovid, in his 'Metamorphoses.' The golden age, when Saturn reigned, is represented as having been that of perfect innocence and happiness; from which the others have gradually degenerated more and more,—the iron age, or that which now subsists, being the most wicked and miserable of all. Sometimes these ages are spoken of as merely so many successive periods in the history of Italy. Saturn having been driven out of heaven by his son Jupiter, is supposed to have sought an asylum in that country, where, in return for the protection he received from King Janus, he taught him and his people agriculture, and the other arts of cultivated life. According to this latter mode of telling the story, it will be observed, the golden age is represented as consisting in the triumph of civilisation over previous barbarism; whereas the other version seems intended to indicate that the primæval state of man was that in which he enjoyed the greatest felicity and purity, and that he has been rather corrupted than improved by what is called civilisation. The two statements, therefore, may be taken as expressing two opposite theories or opinions which have divided speculators upon this subject down even to our own day. The disagreement among the fabulists, however, is only with regard to the original condition of man; it seems to have been admitted on both sides that a gradual declension both of the happiness and virtue of the world has been going on ever since the age of gold. The golden age is that of which the most complete pictures have been drawn; indeed it may be said to be the only one of the four of which the description is at all distinct. The age of iron was deemed to have commenced long before Hesiod's day, who lived probably at least 2600 years ago; it was, in fact, merely a general name for the existing order of things, as distinguished from some imaginary previous state. But neither that immediately preceding state, designated the age of brass, nor its forerunner, the age of silver, is to be found discriminated in the poetic painting by anything more than some slight varieties of shade. Of the golden age, when universal harmony prevailed throughout the living creation, and the bounteous earth yielded her increase untilled, we have various descriptions from the pens of modern as well as of ancient poets. The reader of Italian poetry will recollect in particular the celebrated chorus at the end of the first act of Tasso's 'Aminta,' and the imitation of it at the end of the fourth act of Guarini's 'Pastor Fido.'

AGIO, a term generally used to denote the per-centage difference existing between the values of the current and standard monies of any place. The metallic currency of wealthy states generally consists of its own coin exclusively, and it is in the power of the state to prevent the degradation of that coin below the standard, so that no calculations of agio, strictly so called, are rendered necessary. In smaller states, the currency seldom entirely consists of their own coin, but is made up of the clipt, worn, and diminished coins of the neighbouring countries with which the inhabitants have dealings. Under these circumstances banks were, at different times, established by the governments of Venice, Hamburg, Genoa, Amsterdam, &c., which, under the guarantee of the state, should be at all times bound to receive deposits, and to make payments, according to some standard value. The money or obligations of these banks being better than the fluctuating and deteriorated currency of the country, bears a premium equivalent to the deterioration, and this premium is called the agio of the bank.

To facilitate his money dealings, every merchant trading in a place where the deterioration of the currency is thus remedied, must have an account with the bank for the purpose of paying the drafts of his foreign correspondents, which drafts are always stipulated to be paid in bank or standard money. The practice being thus universal, the commercial money payments of the place are usually managed without the employment of coin, by a simple transfer in the books of the bank from the account of one merchant to that of another. The practical convenience which this plan of making their payments affords to merchants, who would otherwise be obliged, when discharging obligations incurred in standard money, to undergo troublesome and expensive examinations of the various coins in use, causes the money of the bank to bear a small premium above its intrinsic superiority over the money in circulation, so that the agio of the bank does not usually form an exact measure of that superiority.

The term *Agio* is also used to signify the rate of premium which is given when a person having a claim which he can legally demand in only one metal, elects to be paid in another. Thus in France silver is the only legal standard, and payments can be demanded only in silver coin, a circumstance which is found to be so practically inconvenient, that the receiver will frequently pay a small premium in order to obtain gold coin, which is more easily transportable; this premium is called the agio on gold.

AGLAIA. One of the group of small planets revolving between Mars and Jupiter. [ASTEROIDS.]

AGRARIAN LAW was the general title of any law among the Romans which related to the *ager publicus*, or public domain. As the subject of Agrarian laws constitutes perhaps the most important element in the history of the Roman republic, and as an utter misconception of their application has pervaded, till of late years, every work upon the subject, especially the popular writings of Hooke, Ferguson, &c., it seems desirable to place before the general reader a brief account of those more correct views which have been established by the researches of Heyne, Niebuhr, and Savigny.

Ever since the revival of letters it has been a universal error to look upon the agrarian laws, with which the names of the Gracchi and others were connected, as attempts to limit the amount of landed property that any individual might hold; and such an interference with private rights would indeed afford strong ground for condemning any statesman who could be the author of such a proposition, and any state where such a proposition could be favourably received. In the frenzy of the great French Revolution, there were indeed political fanatics, who, following the advice of Macchiavelli and Montesquieu, were willing to enact an agrarian law of this extravagant nature; and so much stress was laid upon the examples of Roman history that Heyne, in March 1793, availed himself of the opportunity offerred to him by the installation of a new pro-rector in the University of Göttingen, to address to that body a paper entitled 'Leges agrariæ pestiferæ et execrabiles' (see his 'Opuscula,' vol. iv. p. 351), in which he successfully contended that the laws so called among the Romans, instead of interfering with private property, solely applied to the lands of the public domain. Heeren and Hegewisch carried the inquiry further; but for the fullest and most satisfactory investigation of the whole subject we are indebted to Niebuhr and his friend Savigny.

As the victorious arms of the Romans extended their authority over one state of Italy after another, the right of conquest gave them a title to the lands of the conquered; but, except in cases of strong provocation, as in the defection of Capua in the second Punic war, it became the clemency of the conquerors to restore a part of the territory to the unfortunate owners. Yet a portion would perhaps always be reserved and added to the public domain. With regard to the disposition of the territory so acquired, we will not go back to an earlier date than the Servian constitution, which gave to the *plebes*, or commonalty, a share in the government, though an inferior one, with the patricians. The disposition of the conquered land was then, we may perhaps say, fourfold. Part was given in full property to religious uses, and part was sold by the quæstors for the supply of the treasury. The plebeians, who constituted the most important part of the army, received assignments of fixed and equal portions in full ownership, never perhaps exceeding seven jugers (that is, between four and five acres) to each individual. These lands were often given under the form of a colony, the parent state sending a body of the citizens to occupy some conquered town, or to found a new one. In all cases the boundaries of lands so assigned were marked out according to the strict principles of Roman limitation, and placed under the religious sanction of the augury. But a large portion of the territory which fell into the hands of the conquerors in the issue of a successful war must often have been in a state of utter desolation, for devastation by fire and sword was a constant and leading feature in ancient warfare; and in a country where the olive and the vine form an important branch of agriculture, such desolation was not easily repaired. Thus large districts were unfit for distribution among the plebeians, or for sale by the quæstors. Moreover, much of the mountain land, and even of the unhealthy plains in Italy, was, as it still is, adapted solely for pasturage, and therefore equally unfit for partition, though far superior in immediate value. The disposition of this unappropriated land, which constituted the permanent public domain, led to a singular mode of occupation. An edict was issued, giving authority, most probably to the patricians alone, to cultivate these lands, but with the full understanding that the state reserved to itself the ownership, and might at any time resume possession,—a right which was from time to time exercised. Yet, though the occupants had no title whatever as against the state, they appear to have been protected against individuals by the interdicts of the prætor, and a branch of law entitled *causæ possessionum*. Under this protection these lands often passed from father to son by a species of permitted inheritance, or as dowries to daughters, or were even transferred to other citizens by purchase; and in this way even plebeians, it would appear, might come into the occupation of them. But, no matter through how many hands the lands might pass, the tenure to the last occupier was as precarious as to the first; and, of course, this was always taken into account in estimating the value. On the other hand, the occupier was subject to certain restrictions and payments. He could not legally hold, at least after the Licinian law, more than 500 jugers (about 333 acres) of this public land; on the public pastures he was limited to 100 head of great, and 500 of small cattle; and he was bound to employ a fixed number of freemen. Some of these restrictions indeed did not always exist, but it seems highly improbable that some regulations of the kind should not have existed from the very beginning, if only to protect one patrician from another. But whatever doubt there may be on this subject, the state was always entitled to the payment of a tenth upon all grain, and a fifth on the olives and the wine, besides some charge, we know not how determined, for the use of the common pasture land. The technical terms used with regard to these possessions were as follows: the lands themselves were called *agri occupati, a. occupatorii, a. possessi, a. concessi, a. arcifinales*, or generally *possessiones*. The holder or *possessor* was said to have the *usus* of them; and the payment he made to the state was the *fructus* or *vectigal*. Instead of collecting this branch of the revenue directly, it was the practice to farm it out, which was expressed by selling or letting the *jus vectigalis* or *fructus*; and in the same sense they used the phrase *agrum fruendum locare*, or even more briefly, though somewhat ambiguously, *agrum locare*.

It must be confessed, indeed, that in this view of the first occupancy of the public domain, there is still something to be cleared up; for a mere edict, such as we have spoken of, without qualification or restriction, would have been little better than an invitation to a general scramble. But it is established incontrovertibly that the possession was simply permissive. If the original occupancy was founded in collusion, the case against the patricians will only be the stronger.

In the various usurpations of the patrician body the restrictions enumerated above were little attended to. The vectigal was rarely paid. While the plebeian was serving in the army abroad, the portion of the public domain possessed by him—and this could only be through purchase—was violently or fraudulently seized by a powerful neighbour. Large districts were monopolised by single holders. It was by them found more profitable to cultivate the land by slaves than by freemen, who were always liable and often called upon to perform military service. Those who held the chief power in the government conspired to deny the title of the state to resume their possessions; and even when new conquests added to the domain, the most desperate efforts were made to resist all further assignments of land to the plebeians, that is, to the very veterans who had effected the conquests. To redress these grievances, or rather to moderate them, agrarian laws were from time to time brought forward; but, we repeat, these laws never interfered with private property. The wealthy might hold land really their own to any amount. The sole object which the reformers had was to check usurpations of the public domain.

We cannot trace the subject historically through the whole existence of the republic, but a few remarks may still be useful. If we look at the birth, the station, the conduct, and the character of the distinguished men whose names are connected with the promulgation of agrarian laws, we shall find little reason for considering them as demagogues. Spurius Cassius indeed lived in a time when we can place little reliance upon the truth of Roman history; but he was himself a patrician, he had thrice been consul, and had thrice triumphed; and though he was eventually tried and executed for treason, the trial took place, not before a plebeian court, as is generally stated, but, as Niebuhr has established, in the 'Comitia Curiata,' where the patricians themselves, whose usurpations he had contended against, were at once his accusers and his judges. For understanding the true character of Licinius Stolo, and the wisdom and justice of his legislation, we will only refer to the first chapter of Niebuhr's third volume. In the time of the Gracchi, it may be thought by many that injustice and tyranny had obtained a title by prescription; but though there may be a question about the policy of the reforms they were endeavouring to introduce, no candid reader of Roman history can doubt the purity of their intentions, or the baseness of the majority among those who resisted them by revolution and assassination. Except the presumed guilt of supporting these agrarian laws, not even their enemies could find a blot in the characters of the two sons of the virtuous Cornelia. Velleius was no friend to democrats, but he says, speaking of the elder Gracchus, *Vir alioqui vita innocentissimus, ingenio florentissimus, proposito sanctissimus, tantis denique adornatus virtutibus, quantas perfecta et natura et industria mortalis conditio recipit.*—("A man in other respect (that is, except in his opposition to the usurpations of the patricians) as to his life most blameless, in ability most distinguished, in principle most upright, in fine adorned with every virtue in as high a degree as man can attain to, when the best gifts of nature are improved by discipline.")—At the same time his opponent Octavius, and his murderer the Pontifex Maximus, Scipio Nasica, were actually offenders under the very law which Tiberius was endeavouring to enforce. On the other hand, the consul Opimius, who headed his party in the premeditated massacre of the younger Gracchus and three thousand of his defenceless countrymen, and then erected a temple to Concord, was afterwards convicted of sacrificing the interests of his country for the gold of Jugurtha. For a full examination of the agrarian laws of Rome, see Niebuhr's 'History,' translation by Hare and Thirlwall, vol. ii. pp. 129—173; and among the ancient writers, Appian's 'Civil Wars,' book i. c. 7—27; Plutarch's 'Lives of the Gracchi;' Dionysius and Livy; Cicero's speech against Rullus, &c.

AGREEMENT, a mutual bargain, contract, or covenant. In its most extended sense, the word comprehends a large proportion of the transactions of civilised man in the mutual intercourse of society, and may even be said to form the basis of society itself. In a more limited and technical sense, an agreement gives rise to those obligations which it is the object of the law to enforce. In the latter sense, agreements are with more propriety termed contracts. All contracts are agreements, but all agreements are not contracts.

When the word agreement is used in its technical sense in the English law, it signifies a "mutual contract, on consideration, between two or more parties;" and the essentials of such an agreement are few and simple.

1. *Assent* is of the essence of an agreement. The parties to a contract must be in a situation to testify their free assent to it. Thus lunatics, infants, and married women are incapable of binding themselves except in some few transactions of necessity. In the purchase of those articles which conventional usage has rendered necessary (and which the law therefore terms "necessaries"), the contracts of the two former classes are obligatory on them; or, in the case of a married woman, on her husband. In the same way, fraud, intimidation, or undue advantage taken by a party to secure a benefit by an agreement, will discharge him who, from ignorance or the operation of external force, has apparently assented to it.

2. The *subject* of agreement must not be tainted with illegality. It would be repugnant to common sense that the law should enforce performance of any act which it had expressly forbidden, or which contravened its general policy.

3. An agreement, to secure the aid of the law in carrying it into effect, must have certain qualities mutually beneficial to the parties, or must be entered into with certain solemnities. Courts of justice cannot be called upon to give effect to every idle or inconsiderate promise. An agreement must either be contracted by a formal instrument in writing, sealed by the party who has bound himself by it, which is technically called a *deed*, and the contract is then a *specialty contract*; or if contracted in a less formal manner, by word or otherwise, it must appear that the parties derive from it reciprocal benefit. This is the meaning of lawyers when they affirm that a *parole* agreement (that is, an agreement not contained in a deed) cannot be legally enforced, unless there be a sufficient *consideration* to support it. Thus A cannot found legal proceedings against B, in respect of a promise made by B to A, unless by the original agreement A was either to confer some reciprocal advantage upon B, or was to put himself to some specific disadvantage at B's request. Upon this principle it is that, by law, a promise to make a voluntary gift can never be enforced. An agreement, thus defective for want of consideration, is called a '*nudum pactum*'—a phrase borrowed from the Roman law, from which also is derived the maxim '*ex nudo pacto non oritur actio*.' It must be added that the '*nudum pactum*' of the civil law differs materially from our simple contracts, which are so called when without consideration.

4. The *form* of agreements has in some cases been regulated by law. The most remarkable instance is that introduced by the Statute of Frauds, in the reign of Charles II., by which among other provisions, it is enacted that contracts in certain cases shall not be available, unless there be some memorandum or note of them in writing, duly signed by the parties to be charged, or their agents. [FRAUDS, STATUTE OF.]

The rules respecting the *construction* of agreements; the various modes by which parties may be released from the performance of them; and the circumstances under which they may excuse or justify non-performance, would form the subject of long legal disquisitions, and would here be obviously out of place.

There are two different remedies for breach of an agreement to which the injured party may resort, according to the nature of his case. He may either seek a pecuniary compensation in the shape of damages for the breach in a court of law; or, in cases where such compensation is inappropriate or insufficient, he may obtain from a court of equity a decree that the party offending shall perform his agreement specifically.

AGRICULTURAL CHEMISTRY. [CHEMISTRY, AS APPLIED TO AGRICULTURE.]

AGRICULTURAL INSTITUTIONS, AND SOCIETIES FOR THE PROMOTION OF AGRICULTURE. The effect of legislative enactments which have for their object the advantage of agriculture are treated of under AGRICULTURAL STATISTICS and elsewhere. The improvement of every branch of rural economy has been largely promoted by agricultural institutions; and those which have been, or are at present, most active in this way, may here be briefly noticed.

The Board of Agriculture, established chiefly through the exertions of Sir John Sinclair, and incorporated in 1793, was a private association of the promoters of agricultural improvement; but as it was assisted annually by a parliamentary grant, it was regarded by the country as in some sort a semi-official institution. One of its first proceedings was to commence a survey of all the English counties on a uniform plan, which brought out, for the information of the class most interested in adopting them, improved practices, originating in individual enterprise or intelligence, and which were confined to a particular district. The 'Surveys' are many of them imperfectly executed, but they were useful at the time, in developing more rapidly the agricultural resources of the country. During the years of scarcity at the end of the last and beginning of the present century, the Board of Agriculture took upon itself to suggest and, as far as possible, provide remedies for the dearth —by collecting information and making reports to the government on the state of the crops. The statistics which the Board collected were also at times made use of by the minister, or at least were believed to be so, in connection with his schemes of taxation. The Board encouraged experiments and improvements in agriculture by prizes; and the influence which it possessed over the provincial agricultural societies excited and combined the efforts of all in one direction. The Board of Agriculture was dissolved in 1816.

The Smithfield Cattle Club, which has been in existence above sixty years, and some of the provincial agricultural societies, especially the Bath and West of England Society, which commenced the publication of its 'Transactions' nearly seventy years ago, have been very useful auxiliaries, if not promoters of agricultural improvement. Until within the last few years, the exertions of Agricultural Societies have been too exclusively devoted to the improvement of stock.

With the establishment of the 'Royal Agricultural Society of England' a new æra commenced in the history of institutions for the improvement of English agriculture. This society, when it was established in May, 1838, consisted of 466 members. At the first anniversary, in May, 1839, the number of members had increased to 1104; and it continued to increase and to prosper.

On the 26th of March, 1840, the society received a charter of incorporation, on which it assumed the designation of the 'Royal Agricultural Society of England.' By the 22nd rule of the Society, "No question shall be discussed at any of its meetings of a political tendency, or which shall refer to any matter to be brought forward, or pending, in either of the Houses of Parliament;" and this rule is made permanent by the charter of incorporation. The objects of the society, as set forth in the charter of incorporation, are: 1. To embody such information contained in agricultural publications and in other scientific works as has been proved by practical experience to be useful to the cultivators of the soil. 2. To correspond with agricultural, horticultural, and other scientific societies, both at home and abroad, and to select from such correspondence all information which, according to the opinion of the society, may be likely to lead to practical benefit in the cultivation of the soil. 3. To pay to any occupier of land, or other person, who shall undertake, at the request of the society, to ascertain by any experiment how far such information leads to useful results in practice, a remuneration for any loss that he may incur by so doing. 4. To encourage men of science in their attention to the improvement of agricultural implements, the construction of farm-buildings and cottages, the application of chemistry to the general purposes of agriculture, the destruction of insects injurious to vegetable life, and the eradication of weeds. 5. To promote the discovery of new varieties of grain, and other vegetables, useful to man, or for the food of domestic animals. 6. To collect information with regard to the management of woods, plantations, and fences, and on every other subject connected with rural improvement. 7. To take measures for the improvement of the education of those who depend upon the cultivation of the soil for their support. 8. To take measures for improving the veterinary art, as applied to cattle, sheep, and pigs. 9. At the meetings of the society in the country, by the distribution of prizes, and by other means, to encourage the best mode of farm cultivation and the breed of live stock. 10. To promote the comfort and welfare of labourers, and to encourage the improved management of their cottages and gardens.

The society has already directed its attention to nearly all the objects above mentioned. The country meetings of the society, which take place annually in July, have perhaps been more serviceable in stimulating agricultural improvement than any other of the society's operations, by concentrating the attention of the society upon each part of the country in succession, and by exciting the attention of each district to the objects which the society is intended to promote. England and Wales are divided into nine great districts, and a place of meeting in each is fixed upon about a year beforehand. In 1839, the first meeting was held at Oxford, at which 23 agricultural implements were exhibited. Meetings have been held since at Cambridge, Liverpool, Bristol, Derby, Southampton, Shrewsbury, Newcastle, Northampton, York, Norwich, Exeter, Windsor, Lewes, Gloucester, Lincoln, Carlisle, Chelmsford, Salisbury, Chester, and with varying fluctuations. The number of implements exhibited had increased in 1858 to 3,438.

There can be no doubt that the mechanics of agriculture have made great progress since the establishment of the society. The opportunity of contrasting and estimating the utility of various implements used for similar purposes in different districts or in different soils, cannot fail to extend improvement from one district to another. One of the principal results effected by such institutions as the Royal Agricultural Society is to introduce the best practices of husbandry from the districts where agriculture is in its most improved state into those where it is most backward. Attached to the society's house there is a reading-room, and a library, to which has been added by purchase the books forming the library of the late Board of Agriculture. As a means of diffusing information on agricultural subjects, the publication of the 'Journal' of the society was commenced in April, 1839, and it has at present a circulation of nearly 10,000. The prize essays and all other communications intended for publication in the 'Journal,' are referred to the Journal Committee, who decide upon the arrangements of the work. The 'Journal' contains besides, very valuable contributions of a practical as well as scientific character.

The success of the Royal Agricultural Society has revived the spirit of existing associations, or led to the formation of new ones. Perhaps in no department of industry or science does there exist so general a spirit of improvement at the present time as in the kindred branches of agriculture and horticulture. Some of the provincial agricultural societies are on a scale which, a few years ago, could scarcely have been anticipated of a central and metropolitan society. The Yorkshire Agricultural Society holds its annual show in the different towns of that county in rotation, a plan which is very successful in rendering them attractive. The Bath and West of England Society in like manner meets annually in a fresh district of its province; and publishes a valuable annual volume of Transactions. In the United Kingdom there are now about 450 local agricultural societies; including farmers' clubs, which have also become numerous. They are eminently practical; but the local results which they collect and discuss may become applicable to other parts of the country placed under similar circumstances of aspect, soil, and situation. It would stimulate the exertions of these clubs, if a department of the 'Journal of the Royal Agricultural Society' were reserved for some of the best papers read at their meetings. The annual report of every farmers' club should be transmitted to the secretary of the Royal Agricultural Society; and the title at least of all papers read at the meetings during the year should be given in the 'Journal.'

The agriculture of Scotland has been largely indebted to the societies which have been established at different periods for its improvement. A "Society of Improvers in the Knowledge of Agriculture in Scotland" was established in 1723, and some of its Transactions were published. The society becoming extinct was succeeded by another in 1755; and the society which now stands in the same relation to Scotland as the Royal Agricultural Society to England was established in 1784. It is entitled the "Highland and Agricultural Society of Scotland." The constitution and proceedings of the society are as nearly as possible similar to the English society. The society publishes quarterly a very excellent Journal of its Transactions, which has at present a circulation of 2300. The Agricultural Museum at Edinburgh was assisted in 1844 by a parliamentary grant of 5000*l.*

In 1841 the 'Royal Agricultural Improvement Society of Ireland' was established on the plan of the Royal Agricultural Society of England; and in May, 1844, the number of subscribers was 581. Since its establishment great progress has been made in the formation of local societies in communication with the central society, which is the best means of ensuring the support and co-operation of the agricultural class in every part of the country. In 1841 there were only twenty-three of these bodies in existence; in 1858 there were sixty-nine. A very judicious arrangement has been made relative to the prizes distributed at the local meetings, which are now given for operations in husbandry only, the premiums for stock being furnished by the local association. The society has established an agricultural museum in Dublin for the reception of implements of husbandry, seeds, grasses, &c.; it circulates practical information connected with husbandry by means of cheap publications; and one of its objects is the organisation of an agricultural college. There is also the Royal Dublin Society for the Promotion of Husbandry, &c., which holds a cattle show and gives prizes annually for stock and agricultural improvements, and which possesses a good agricultural museum in the society's house in Kildare Street.

In England there are no institutions of a public nature which combine scientific with practical instruction in agriculture. The advantage of establishing such an institution was suggested by the poet Cowley; and in 1799 Marshall published 'Proposals for a Royal Institute or College of Agriculture and other branches of Rural Economy.' There is the Sibthorpian Professorship of Rural Economy in the university of Oxford; at the university of Edinburgh, a professorship of agriculture; and at the university of Aberdeen there are lectures on agriculture. The botanical, geological, and chemical professorships and lectures in the different universities are, to a certain extent, auxiliary to the science of agriculture. In the absence of such establishments as the one at Grignon, in France, young men are sent as pupils to farmers in the counties where the best system of agriculture is practised, especially Norfolk, Lincolnshire, Northumberland, and the Lothians; but although this may be a good plan for obtaining practical knowledge, it is imperfect as regards the knowledge gained of the scientific principles of agriculture. The Earl of Ducie established a model or example farm on his estate in Gloucestershire, where the scientific principles of agriculture were carried into operation; but this was very different from an institution which imparts a knowledge of these principles. In 1839 the late B. F. Duppa, Esq., published a short pamphlet entitled 'Agricultural Colleges, or Schools for the Sons of Farmers,' which contains many useful suggestions for the establishment of such institutions. He laboured indefatigably in the promotion of this object, and probably would have succeeded but for his premature death. Cirencester College, which was established in 1846, and originated in a paper on Agricultural Education, read by Mr. Robert J. Brown of that town before a local farmers' club, gives instruction in the higher branches of agricultural knowledge. Students are admitted either as boarders or out-students, the first class paying from 55 to 80 guineas per annum; the last, 40 guineas. The college is conducted by a principal, with professors of chemistry; of zoology, geology, and botany; of veterinary medicine, and surgery; of surveying, civil engineering, and mathematics; and of practical agriculture. The college has acquired a high reputation, is consequently well attended, and therefore prosperous.

Schools of industry, similar to the one established by the late Rev. W. L. Rham at Winkfield, and by the Earl of Lovelace at Ockley, may be made the medium of imparting an acquaintance with the principles of agriculture, which at present the labouring classes do not usually obtain. Other institutions of a like nature have been established in various places, and at the Reformatory School at Redhill, where a farm is cultivated by the boys, who are thoroughly instructed in practical agriculture.

In Ireland the government affords direct encouragement to agricultural education through the instrumentality of the Board of National Education. The persons who are trained for the office of teachers in the national schools are required to attend the lectures of a professor of agricultural chemistry; and during a portion of the time occupied in preparing for their future duties they are placed at the model farm at Glasnevin, where they are lodged, and where, during five mornings of the week, they attend lectures on the principles of agriculture; and an examination subsequently takes place. On the sixth morning they are taken over the farm, and the operations going forward are explained to them. The Board admits a certain number of in-door pupils for the term of at least two years, who pay 10*l.* a year for board, lodging and education. They work on the farm, attend the lectures, and receive such instruction as qualifies them to fill the office of bailiffs. There is likewise a class of schoolmasters trained to conduct agricultural schools. Thirty-seven model schools are established in different parts of the country. The Agricultural Seminary at Templemoyle, six miles from Londonderry, is one of the most successful experiments which has yet been made in the United Kingdom to establish an institution for agricultural education. It was founded by the North West of Ireland Society. The plan is in some degree taken from the institution established by M. Fellenberg, at Hofwyl, in Switzerland. An account of the institution and of the course of instruction will be found in the 'Minutes of the Committee of Council on Education,' p. 565, 8vo, ed. Power has also been given to Boards of Guardians to hold land for the purpose of instructing the workhouse boys in agricultural labour, and the plan has been adopted by many unions with considerable success.

Such societies as the Scottish Agricultural Chemistry Association, established at the close of 1843, were very well calculated to advance the progress of scientific agriculture; and they might be established in any district where a sufficient number of subscribers can be obtained to command the services of a competent chemist. Associations of this nature show how much can be done in this country without any assistance from the state. The object of the Scottish association was the diffusion of existing information, theoretical and practical, by means of occasional expositions, addresses, and correspondence; and secondly, the enlargement of the present store of knowledge by experimental investigations of practical agriculturists in the field and of the chemist in the laboratory. Landed proprietors who subscribed twenty shillings yearly, and tenants who subscribed ten shillings yearly, were entitled to have performed analyses of soils, manures, &c., according to a scale fixed upon; and if more than a certain number were required, a charge of one-half above the scale was made. Letters of advice, without an analysis being required, were charged 2*s* 6*d*.. Every agricultural society subscribing 5*l.* yearly to the funds of the Association was entitled to one lecture from the chemist; if 10*l.* to two lectures, &c. Counties which subscribed 20*l.* annually were entitled to appoint a member of the Committee of Management. The chemist of the association had his laboratory at Edinburgh, but he visited various parts of Scotland according to certain regulations. We give the details of this institution, though obliged now to speak of it in the past tense. It was well deserving of a longer life; and might be usefully revived upon a smaller scale in many limited localities. In Scotland most of its offices are now accomplished by the chemical officer of the Highland and Agricultural Society.

In France there are schools assisted by the state, where young persons can obtain instruction in agriculture, both practical and theoretical. The principal institution of this kind is that at Grignon, where one of the old royal palaces and the domain attached to it, consisting of 1185 acres of arable, pasture, wood, and marsh land, has been given up on certain conditions. The professors are paid by the government, and the pupils are of two grades, one paying 48*l.* a year, and the other 36*l.* For the purpose of imparting theoretical knowledge, courses of lectures are given on the following subjects: 1, The rational principles of husbandry, and on the management of a farm; 2, The principles of rural economy applied to the employment of the capital and stock of the farm; 3, the most approved methods of keeping farming accounts; 4, The construction of farm-buildings, roads, and implements used in husbandry; 5, Vegetable physiology and botany; 6, Horticulture; 7, Forest science; 8, The general principles of the veterinary art; 9, The laws relating to property; 10, Geometry applied to the measurement and surveying of land; 11, Geometrical drawing of farming implements; 12, Physics as applied to agriculture; 13, Chemistry, as applied to the analysis of soils, manures, &c; 14, Certain general notions of mineralogy and geology; 15, Domestic medicine, applied to the uses of husbandmen. The practical part of the education is conducted on the following system:—The pupils are instructed in succession in all the different labours of the farm. Some, for instance, under the direction of the professor of the veterinary art, perform the operations required by the casualties which are continually occurring in a numerous stock of cattle. Others are appointed to attend to the gardens, and to the following departments: woods and plantations; inspection of repairs taking place on the premises; making of starch, cheese, and other articles; the pharmaceutical department; book-keeping and the accounts. A daily register is kept of the amount of the manure obtained from the cattle of every kind. A pupil newly entered is appointed to act with one of two years' standing; and at the end of each week all are expected to make a report, in the presence of their comrades, of whatever has been done during the week in their respective departments. The professor, who presides over the practical part of their education, explains on the spot the proper manner of executing the various field operations; and he also gives his lectures on these different processes at the time when they are in actual progress. The professors in each department render their courses as practical as possible;—the professor of botany by herborisations; the professor of chemistry by geological excursions; the professor of mathematics, by executing, on the plan he has pointed out, the survey and measurement of certain portions of land. After two years' training in the theory and practice of rural economy, the pupils undergo an examination from the professors collectively, and, if satisfactory, a diploma is granted, which certifies to the capacity of the pupil for fulfilling the duties of what may be styled an 'Agricultural Engineer.'

Institutions designed for the improvement of agriculture, and supported by the state, have been established in most parts of Germany. In Prussia there is a public model farm and agricultural academy in nearly every province. The most important of these institutions is the one at Mögelin, in Brandenburg, about 40 miles from Berlin, which was founded by the late king. Von Thaer was at one period the director. The establishment consists of a college and a model farm of 1200 acres. When visited by Mr. Jacob, in 1820 ('Agriculture, &c., of Germany'), there were three professors, who resided upon the premises; one for mathematics, chemistry, and geology; one for the veterinary art; and the third for botany and the use of the various vegetable productions in the Materia Medica, as well as for entomology. Attached to the institution there was a botanic garden, arranged on the Linnæan system; an herbarium; a museum containing skeletons of domestic animals, models of agricultural implements, specimens of soils, &c. The various implements were made in workshops upon the farm, and the pupils were expected to acquire a general notion of the modes of constructing them. The sum paid by each pupil was very high, not less than 80*l.* a year.

At Hohenheim, in the kingdom of Würtemberg, two leagues from Stuttgard, an old palace has been appropriated as an agricultural college. The quantity of land attached to the institution is about 1000 acres. The pupils are of two grades, and those belonging to the superior class pay for their board 150 florins, and for their instruction 300 florins a year, or altogether 37*l.*, and extra expenses make the annual cost about 50*l.* Natives of Würtemberg are admitted at a lower rate than the subjects of other states. The higher class of students do not, as at Grignon, take part in the actual labours of husbandry; but the means of theoretical instruction are very complete. Lectures are delivered by twelve professors on the following subjects:—Mathematics and physics, chemistry and botany, technology, tillage and other departments of rural economy, forestry, and the veterinary art. The lectures are so arranged that they can be either attended in two half-years or three or four. In the former case much preliminary information must have been acquired. There is attached to the institution a small botanical garden; a museum of zoological, botanical, and mineralogical objects; skeletons of domestic animals; collections of seeds and woods; and a library of works on rural economy. The establishment also comprises a manufactory of beet-root sugar, a brewery, a distillery of potato-spirit, and there is an apartment devoted to the rearing of silkworms. A part of the farm is reserved for experiments. The second class of students do the manual labour, but they are nearly maintained at the expense of the institution, and, when they can be spared from field-labour, they have the opportunity of attending the lectures at the college.

In Bavaria the king has given up the domain attached to the royal palace of Schleissheim for the purposes of a model farm; but a great mistake has been made in selecting land much below the average standard of fertility, which, as well as land of extraordinary productiveness, should be avoided. It is on a much inferior scale to the establishment at Hohenheim. There are agricultural institutions supported by the state at Vienna, Prague, Pesth, and various other places in the south-east of Europe. We add to these remarks the following enumeration of European Agricultural Educational Institutions, extracted from a report by Dr. Hitchcock to the legislature of Massachusetts:—

	Superior Schools.	Inter-mediate.	Inferior.	Special.	Parts of Colleges.	Total.

Although the column containing a reference to such agricultural institutions as form parts of colleges is blank opposite England, it should be mentioned that since the date of Dr. Hitchcock's report, the Trustees of the Queen's College at Birmingham have established an agricultural lectureship, and appointed Mr. Henry J. Tanner, of the Cirencester Agricultural College, their first Professor of Agriculture.

(*On public Institutions for the Advancement of Agricultural Science*, by Dr. Daubeny; *Journals of Royal Agric. Soc. of England*; Dr. Lindley's *Gardener's Chron. and Agric. Gazette*, &c. &c.; Thom's *Almanac and Official Directory* for Ireland).

AGRICULTURAL IMPLEMENTS. Few of the productive arts have made more signal progress within the last few years than those which relate to the cultivation of the soil. This progress is mainly due to four causes. First, the Repeal of the Corn Laws. The abandonment of protective duties on home produce has compelled the farmer to depend on his own resources. He is now placed in a position to feel the effects of any superiority or advantages possessed by foreign farmers; and he is urged by every motive of self-interest to maintain his ground. Those circumstances which depend upon political or fiscal regulations, and those which are due to climate or natural causes, he must bend to, if he cannot make them bend to him; but, in all the practical details of his art, he is more alive to what is going on around him than at any former period in the history of British farming. Second, the progress of agricultural chemistry. The chemical researches of Liebig and others have led to marked improvements, especially in the implements for distributing and otherwise treating manures. Third, the Royal Agricultural Society. The exertions of this admirable society—in conducting experimental researches, offering prizes for useful novelties, holding annual shows or exhibitions, drawing up reports on the agriculture of particular places at particular times, the popularisation of the results obtained by scientific men, and the publication of papers relating to all branches of agricultural art—have had a great effect in leading to improvements in the implements of farming. Fourth, the Great Exhibition of 1851. That wonderful assemblage, by comprising implements from foreign countries (many of which had not been seen here before), and by leading to the institution of many valuable series of experiments on groups of implements, gave a very notable impetus to the makers of agricultural implements, and, through them, to the farmers. The annual country exhibitions of the Royal Agricultural Society, as well as the metropolitan show of the Smithfield Cattle Club, have demonstrated how great has been the advance made in this art between the years 1851 and 1858. The Royal Agricultural Society's 'Trials' of implements have now assumed an important systematic arrangement. At the suggestion of the late Mr. Pusey, all agricultural implements have been placed in three groups, according as they relate to the preparation of the ground for sowing, the treatment of the crop from sowing to gathering, or the subsequent processes of the barn, &c. Trials of implements in the three classes take place in turn. At the Chelmsford meeting in 1856, for instance, the trial was of implements in the first class; at the Salisbury Meeting in 1857, it related to the second class; and at the Chester meeting in 1858 to the third. This plan has been since extended, and a quadrennial division is to be adopted for the future.

The present article is devoted to a general notice of the mechanical implements of agriculture, and of the kind of service which each is fitted to render—with cross-references to such special articles as may be found under other headings in the Cyclopædia. The details may be conveniently arranged under certain headings—Instruments of Tillage; Implements of Cultivation; Harvesting Implements; Preparations for Market; Implements for Stock-feeding; Land-draining; and the application of Steam Power to Agriculture. To some extent it will be necessary to describe processes and their objects; but for the most part the implements only will be treated of.

Instruments of Tillage.

Ploughs.—The better the soil, the less cultivation it requires to produce tolerable crops; hence, where the land is very rich, we find in general a slovenly culture; where the ground is less productive, more labour and skill are applied to compensate for the want of natural fertility. The simplest cultivation is that of the spade, the hoe, and the rake,—and on a small scale it is the best; but spade husbandry cannot be carried to a great extent without employing more hands than can be spared from other occupations. The plough, drawn by oxen or horses, is the chief instrument of tillage, and has been so in all ages and nations of which we have any records. A plough [Plough] should as much as possible imitate the work done with a spade. It should cut a slice from the land by its coulter vertically, and by the share horizontally lift it up, and turn it quite over by means of the mould-board; the art of the ploughman consists in doing this perfectly, and with such a depth and width as suit the soil and the intended purpose. In rich mellow soils a ploughed field should differ little from a garden dug with the spade. In tenacious soils, the slice will be continued without breaking, especially if bound by the fibres and roots of plants; the whole surface will be turned over, and the roots exposed to the air: it is of great consequence that all the slices be of the same width and thickness, and the sides perfectly straight and parallel. The plane of the coulter must be perfectly vertical, and that of the share horizontal, in order that the bottom of the furrow may be level, without hollows or *baulks*, which are irregularities produced by the rising or sinking of the plough, or inclining it to either side. The ancients were very particular in this respect, and recommended sounding the earth with a sharp stake, to ascertain whether the ploughman had done his duty. There are various modes of ploughing land, either quite flat, or in *lands* or stitches, as they are called in England, and, in Scotland, *riggs*, that is, in portions of greater or less width, with a double furrow between them—somewhat like beds in a garden. Sometimes two ridges are set up against each other, which is called ridging or *bouting*; the land then is entirely laid in high ridges and deep furrows, by which it is more exposed to the influence of the atmosphere and kept drier; this is generally done before winter, especially in stiff wet soils. Sometimes two or more ridges are made on each side, forming narrow stitches. When the ground is to be ploughed without being laid in lands or stitches, and all the ridges inclined one way, the mouldboard of the plough is shifted at each turn from one side to the other. The plough which admits of this is called a *turn wrest plough*, and is in general use in Kent, and in many parts of the continent, where the subsoil is dry and the land not too moist. In most other situations the ground is laid in *lands*, and the mould-board of the plough is fixed on the right side. When grass land or stubble is ploughed, care must be taken to bury the grass and weeds completely, and the slice cut off by the plough must be turned over entirely, which is best done by making the width of the furrow greater than the depth. When the grass and weeds are rotten, and the ground is ploughed to pulverise it, a narrow deep furrow is best; the earth ploughed up is laid against the side of the preceding ridge, which forms a small furrow between the tops of the ridges, well adapted for the seed to lodge in and to be readily covered with the harrows.

Nothing has more divided agriculturists than the question, whether the land should be ploughed deep or shallow; but a slight attention to the purposes for which land is ploughed, and to the nature of the soil, will readily reconcile these apparently contradictory opinions. A deep, rich, and stiff soil can never be moved too much nor too deep: deep ploughing brings up rich earth, admits the air and water readily, and gives room for the roots to shoot; while the rich compact soil affords moisture and nourishment. Wherever trees are to be planted, the ground should be stirred as deep as possible, even in a poor soil; for grass and corn, this is not, however, in ordinary practice found prudent; though their roots descend below the cultivated 'staple,' yet these crops are found in general to succeed best when the subsoil is left unloosened.

The great object in ploughing land is to divide it, expose every part of it to the influence of the elements, and destroy every plant or weed but those which are sown in it. To do this perfectly requires several ploughings, with certain intervals, and during that time no crop can be upon the land. This is the real use of fallows, and not, as was once supposed, to allow the land to rest; on the contrary, it ought then to have the least repose.

Harrows. Referring to the article PLOUGH for an account of the recent improvements in that important implement, we proceed to notice the other implements in connection with the processes of arable culture.

After the harvest, the plough is set to work, and the stubble ploughed in. The winter's frost and snow mellow it, while the stubble and weeds rot below. In spring, as soon as the weather permits, it is ploughed again, to complete the decomposition of the roots and weeds. The *harrow* is then, in most cases, employed, to stir the ground and tear up the remaining roots. The bush-harrow consists of a row of twigs or branches, fixed to a frame, and drawn over the surface of the ground. But this is intended rather for covering the seed with a light layer of earth, than to prepare the ground for sowing. The ordinary harrows have several rows of iron teeth or tines, which dig into the ground, and assist in comminuting the clods of earth. Until recently, the harrow was made with bars set square, and with teeth one behind another on each bar; to prevent the teeth, therefore, from dragging after each other in the channels, it was necessary to draw the harrow in an awkward way from the corner. In Williams's patent harrow the bars are set diagonally, at such an angle that every tooth, when the harrow is drawn square, may mark out a furrow for itself. In Howard's harrow, the diagonal arrangement is combined with a zig-zag framing, having a somewhat similar object in view. In Coleman's expanding harrow, the bars at every point of crossing are united by a loose pin instead of a screw; the effect of this is, that the width of the harrow can be increased or diminished, and the teeth can be brought nearer or farther apart, so as to suit the state of the land. This harrow has also very small wheels, which can be let down while it has to be conveyed from one field to another.

Scarifiers; Grubbers; Cultivators.—Various instruments have been invented to stir and mix the earth, without so often using the plough as was necessary in the old mode of farming, and also to loosen and separate roots and weeds. The scarifiers, grubbers, and cultivators now in use are all examples of this kind of implement. One of the earliest was Plenty's scarifier, which acted as if a large number of very small ploughs were working at once in one frame, each digging only to a small depth into the ground. The teeth, shares, or tines, were easily removable, so as to be replaced by others of different size or shape, according to the state of the soil; and when inserted they could be raised or lowered at pleasure, as a means of making a shallow or a deep incision. This implement divided the soil, but did not turn it over; it was well calculated to destroy roots and weeds, and to let in the air, but it was only adapted to tolerably loose and mellow soils, free from large stones. Finlayson's harrow or cultivator rakes the weeds out of the ground, and throws them on the surface without clogging the instrument. Farmers value the various kinds of cultivators and scarifiers chiefly on the following ground;—in a four-course system of husbandry, there are frequently seven ploughings in the four years; but by the use of these implements at certain seasons, working many tines or shares at once, but going only to a small depth, the regular ploughings may be reduced in number, and the total result produced by one-half the ordinary labour of man and horse. The implement-makers have vied with each other in ingenious modes of insuring these results. Coleman's scarifier, with six horses, is adapted for very hard ground. Biddel's, made by Messrs. Ransome, is suitable for deeper incisions into looser ground. Kilby and Bentall's paring-ploughs are midway in character between ordinary ploughs and scarifiers, and are useful for a very close surface of land. Cotgreave's plough is a cultivator, in which three processes are combined in rather a curious way; it first ploughs and turns a furrow five inches in depth; then it digs another five-inch furrow, inverts the soil, and deposits it on the top of the first; and lastly, a sub-pulveriser loosens the soil to a further depth of three or four inches. Beauclerk's patent plough and subsoiler may be likened to a common plough with an Archimedian screw attached, which revolves in the bottom of the furrow, thus ploughing and subsoiling at the same time. At the Smithfield Cattle Show in 1858, one of the implements exhibited was Romaine's cultivator or digger, which takes up and turns over larger masses of earth than is customary with other implements of the kind. A digging action is effected by Owen's potato-digging plough, exhibited on the same occasion; with this machine, two horses and one man can dig potatoes as rapidly as twenty persons can pick them up.

Rollers; Clod-crushers.—When the soil turned up by the plough is in large hard lumps, a roller, sometimes with spikes on its surface, is drawn over the land to break the clods, or mallets are used to break them by hand; but this is seldom necessary, except where very stiff soils have been ploughed when too wet, and the ridges have dried, and been ploughed again in dry weather. Deep wet clay soils require watching, to determine the proper time for ploughing; frost is the best pulveriser; and if they be kept from wet by careful draining in autumn, they will be loose and friable in spring. On light soils the plain roller is used with advantage to produce firmness, and to hinder a too rapid evaporation of moisture. Farm-rollers, like other agricultural implements, have undergone many improvements. "Not many years ago," said Mr. Philip Pusey, one of the most enlightened encouragers of scientific agriculture, "the landlord was often asked by his tenant for some old tree to convert into a roller; the tree-roller, when manufactured, had its framework loaded with rough materials to give it weight; but it soon wore and cracked, so as to become in a year a most ungainly implement." Iron rollers of excellent construction have since been introduced. For rendering the soil fine, however, the regular cylindrical form has one disadvantage, seeing that it passes so easily over small clods as to press without crushing them. Hence the invention of various kinds of *Clod-crushers.* M. Claes, of Belgium, has invented a roller intended for narrow round ridges, but also fitted to produce the crushing instead of the pressing action. It consists of four rings or partial rollers, so adjusted on one axis as to have independent and irregular movements. The best machine now in use in England for this purpose is Crosskill's clod-crusher. It is a roller of which the surface is jagged by iron teeth. Its principal use is in breaking down turnip land which has been fed off by sheep in wet weather, and afterwards baked by the heat of the sun; but it is also usefully employed as a presser for young wheat in March, when the soil has been swollen and the roots thrown out by alternating frosts and thaws. According to the competent testimony of Mr. Pusey, by using this implement on barley-land at the proper time, the necessity is avoided of sowing on cloddy ground, or of delaying the sowing for three weeks—in either case ensuring an additional quarter of barley per acre, and thus paying for the implement in the very first season. Another kind of clod-crusher, Gibson's, is adapted for a moist state of the soil; it is formed of two rows of very narrow wheels, alternating one with another. Patterson's self-cleaning clod-crusher contains a series of eccentrics upon an axle, which, in revolving, rub and clean each other. Crosskill's Norwegian harrow differs from his clod-crusher in having very long and fine teeth; it does not clog between the teeth, nor does it knead the soil. It is evident that each kind of clod-crusher is suitable for a particular state of the ground.

Many of the implements employed in the preparation of the ground for culture are now tested by dynamometers, or power-measurers, which show in what ratio the power employed is made to render useful service. At the Newton Abbot meeting of the Bath and West of England Agricultural Society, in 1857, several such instruments were submitted to trial. One showed the draught of ploughs and cultivators, from one to six-horse power; another ascertained the power consumed by horse-gear, independently of the machines to which it may be attached; while another tested the power of threshing and other rotary machines.

IMPLEMENTS OF CULTIVATION.

Sowing; the Dibble.—When the soil has been prepared by means of the implements above described, the processes of cultivation follow, including the sowing of the seed and the treatment of the growing crops. In arable land, the most common method is to sow the seed after the last ploughing, and draw the harrow over to cover it; the seed, if the land has been well ploughed, will mostly fall into the small furrows made by two adjoining ridges, and rise in regular rows. A more careful method, however, is that of *dibbling,* adopted in some of the eastern counties. The dibble is a rod about 30 inches long, having an oval ring for a handle at one end, and at the other a cone-shaped projection. With two of these dibbles, one in each hand, the sower makes small holes 4 or 5 inches apart, in rows 9 to 12 inches asunder; he pushes and turns the dibbles, to make clear holes, walking backwards along the furrows. Two or more children follow, and drop three or more grains in each hole; a bush-harrow is drawn over the ground, and fills the holes with loose earth. Great improvements have been made in the construction of hand dibbles, by which several holes are made and seed deposited in them by one operation. A dibble manufactured by Mr. Powell is one of the best of this class.

Drills.—Broad-cast and dibble sowing have, however, been almost abandoned in modern English farming. One half of the horse power formerly expended in harrowing is saved by the adoption of some of the modern drills or seed-sowing machines; a saving of seed is also effected; and there is also an avoidance of the necessity for that previous harrowing into ridges at a particular angle, which was formerly deemed necessary as a preliminary to hand-sowing. The drill is, in fact, the key to a whole system of husbandry; for, in addition to the advantages just enumerated, this machine is applicable to the use of many artificial manures, distributing them beneath the ground by means of special coulters, and covering them with earth, that their excessive strength may not injure the seed, which is deposited last of all. The use of the horse-hoe is almost wholly dependent on the previous use of the drill; indeed, the two bear to each other much the same relation as the hand-hoe and the dibble. For the construction and action of seed-drilling machines, see DRILL.

Top-dressers; Manure-distributors.—Wheat crops are usually provided with their requisite manure by farm-yard refuse or by sheep-folding. It usually, however, requires a top-dressing of manure during its growth. It was customary, a few years ago, to apply this by hand; but machines are now usually employed. These will distribute three or four bushels per acre of guano, rape-cake, superphosphate, nitrate of soda, or other fertilising agent. Holmes's top-dresser is a favourable example of this kind of implement. A more complicated machine is that by which manure is deposited either with the seed, or at least with an equal degree of regularity. Some among the many forms of drill are applicable to this purpose; and our implement makers now bestow great attention upon this department of their art. Thus, Reeves and Beaton's liquid-manure distributor consists of a series of buckets or troughs, attached to a metal chain or band; the chain works round two rollers as the vehicle progresses, the wheel giving the motive power to the rollers. Chandler's water-drill is an ingenious contrivance for depositing water as well as pulverised manure, at certain dry seasons. Some of Hornsby's drop-drills not only limit the seed and manure to particular lines, but to particular points in these lines, thereby increasing still more the economical action of drills. At the Salisbury meeting in 1857, Reeves's manure-distributor received much commendation: it comprises a box in which revolve a row of archimedean screws; these turn the dry powdered manure out at holes in the bottom of the box,—a slide, by diminishing or increasing the openings, regulating the quantity to be deposited.

Hoe; Horse-hoe.—Among the necessary implements for treating the young plants during their development is the hoe—worked by hand in the old-fashioned method, and by horse-power in the improved modern farming. [HOE; HORSE-HOEING.]

HARVESTING IMPLEMENTS.

Reaping Machines.—The operation of cutting the corn when it is ripe, is one of so important a character, that inventors have made many attempts, during the last century, to produce machines that shall effect this by horse-power instead of by the sickle or reaping-hook. The ingenious labours of M'Cormick, Hussey, Bell, Crosskill, and other machinists, in this department of their art, will be best noticed in connection with the process of reaping generally, under REAPING; REAPING MACHINES.

Horse-rakes.—Even the rakes which collect the scattered corn in a field are now to be numbered among horse-worked implements. The modern horse-rake used in many of our counties, is an implement about 8 feet wide, running on low wheels, and having about 30 prongs or teeth; it is drawn by one horse rapidly between the rows of cocked barley, &c., and is tipped up from time to time by a man who follows. One of these machines will do the work of about twelve women. At the Newton Abbot meeting in 1857, three or four "self-acting" horse-rakes were tried; but the automatic action was not in general satisfactory. At the Salisbury meeting the specimens were much more numerous, exhibiting many ingenious modes of overcoming difficulties.

Hay-making Machines.—The simple use of the fork to turn and toss the hay in the field, is now to some extent superseded by hay-making machines. Those which were first introduced, flung up the hay high in the air; but they are now so constructed as gently to stir it, without raising it to any great height. The hay-making machine is something like a paddle-wheel, with teeth or spikes in all the paddle-boards or floats. It is set in rotation by the wheels of the carriage to which it is attached. Its labour-saving effect is analogous to that of the horse-rake. Rowsell's hay-collector is a favourable example of this kind of implement. At the Salisbury meeting, the hay-making machines sent by Nicholson, Barrett and Exall, Smith and Ashby, Thompson, Nicholson, and other makers, worked so excellently as to show that this kind of process has been fairly brought within the range of machinery. Several instruments of minor character might be comprised under this particular section of our article: such as Allen's grass-mower, exhibited at the Smithfield Show in 1858; it will cut grass better and lower than the scythe, and at the rate of an acre per hour. Kinnaird's, Mazier's, Clayton's, and Catchome's, are all useful instruments for cutting clover or grass, each being suited for a particular kind of work.

PREPARATIONS FOR MARKET.

Carts and Waggons.—The conveyance of agricultural produce from the field to the barn, and from the barn to market, has not failed to enlist the attention of implement-makers. Many improvements in these vehicles have been recently introduced. The old-fashioned capacious tumbril for carting earth and dung, with broad wheels to prevent them sinking in soft ground, is too well known to need description. The best-constructed carts have iron axles, with the ends or arms turned smooth, and slightly conical. The light Scotch cart, drawn by one horse, is justly regarded as a useful vehicle for transporting earth or manure, especially in hilly countries. It is low and short, so that the horse draws very near the centre of gravity; and the load may be so adjusted as to bear more or less on the horse, according to the steepness of the road. The Scotch cart is made to carry hay and straw by means of a light frame, which is laid on it and projects over the body and wheels in every direction. To ease the weight resting on the back of the horse, carts have been invented with three wheels, the small additional wheel being made to turn in front; but they have disadvantages which counterbalance their advantages.

The Agricultural Jury Report on the Great Exhibition of 1851, announced a very marked improvement in recent years in the construction of agricultural carts and waggons, especially in the use of single-horse carts instead of pair-horse or three-horse waggons. "It is proved beyond question, that the Scotch and Northumbrian farmers, by using one-horse carts, save one-half of the horses which south-country farmers still string on to their three-horse waggons and dung-carts. The said three-horse waggons and dung-carts would also cost nearly three times as much original outlay." The implement-makers have shown that single-horse carts can be made suitable for any farming purpose. Mr. Busby's cart is one which has come largely into use. So much attention has recently been paid to this subject that, in a competitive trial at Grantham, five horses with five new carts were tried against ten horses with five old waggons, and clearly beat them in the amount of work performed. Some makers now attend most to the form of the harvest-cart, that the corn may be carried more steadily; some endeavour to make the cart low, for ease of loading and of draught; some try to give horizontality to the shafts; some make their wheels by machinery; while others strive for excellence in a 'cart-of-all-work,' which shall be adapted to as many kinds of farm-service as possible. At the Great Exhibitions in London and Paris (1851 and 1855), foreigners were much struck with the superior neatness and compactness of English farm-carts, over those made and used on the Continent. At the Salisbury meeting in 1857, a prize was offered for "the best one-horse cart, constructed with a view to lightness of draught and the ready loading and unloading of farm produce,—qualities which may be best attained by the judicious use of long shafts, high wheels, and cranked axles." This prize led to the production of a number of excellent carts for agricultural purposes.

Threshing Machines.—The important process of separating the corn from the husk used, in former days, to be effected by means of a flail beating against a threshing-floor; but farmers are now becoming more and more accustomed to employ the improved implement called the threshing-machine. For the simpler process, see BARN; and for the more complicated but more efficient, THRESHING; THRESHING MACHINE.

Winnowing and Dressing Machines.—These are so intimately allied with the machines last mentioned, in their purpose and action, that they may usefully be noticed together, under THRESHING; THRESHING MACHINES.

IMPLEMENTS FOR STOCK-FEEDING.

Turnip-Cutters.—The preparation of fodder for animals has become a department of farming in which many useful and ingenious implements are employed. It has been found that the labour of the jaws in masticating uncut food, tends to waste the muscle of the farm animals and retard their growth; it is therefore now a custom to cut or bruise most of the kinds of fodder for such animals. The *turnip-cutter* is one of the implements employed for this purpose. There is no doubt considerable advantage in the use of a turnip-cutter to the animals individually so fed, but the principal economy of the process arises from its saving much of the roots as food which is otherwise trodden down in the sheep-pen. Lambs fed with the aid of a turnip-cutter would be worth more at the end of a winter by 8*s.* a head than lambs fed on whole turnips, thus effecting a saving of about 70*s.* per acre on turnip crop. The turnip-cutters vary greatly in action, some cutting by a vertical, and others by a rotatory movement.

Chaff-Cutters.—Another implement of this class is the chaff-cutter. There not being enough natural chaff for the use of farm animals, artificial chaff is made by cutting straw into very small pieces. At first the straw was cut by a chopper, but cutting-machines were afterwards introduced; they usually consist either of a blade working vertically, or of one or more cutters ranged on a wheel; but in some large farms the cutters are worked by means of a strap connected with a fixed or moveable steam-engine. The process now costs only one-sixth or one-eighth of the charge formerly incurred. There was a trial of chaff-cutters during the Agricultural Meeting at Carlisle in 1855, in which one apparatus, made by Cornes, cut 1485 lbs. of chaff per hour by steam-power; those that worked by the muscular power of one man each cut quantities varying from 90 to 210 lbs. per hour. In Brown and May's screw-cam chaff-cutter, exhibited at the Smithfield Show in 1858, there are feed-rollers, which hold the hay or straw firmly while the knife is passing through, and these rollers move round to bring it forward in the space between the knives, ready for the next cut.

Crushers, Grinders, and Bruisers.—These machines, mostly of modern introduction, act by the crushing movement of rollers rather than the grinding movement of mills, and are intended to facilitate the comminution of substances for cattle-food. One is a linseed-crusher; another a corn-crusher; a third, an oil-cake bruiser; a fourth, a fine-meal mill; a fifth, a gorse-bruiser. It is evident, from a mere inspection of this list, that there is much scope for ingenuity in the arrangement of working parts for such machines. Some of the fine-meal mills, made principally to crush barley, beans, and oats, admit of adjustment that will "enable them to grind anything from linseed up to flint stones." Messrs. Hornsby, Garrett, Crosskill, and other manufacturers, now make steam-worked oil-cake breakers that will break 3000 lbs. of cake per hour for sheep, or 4000 lbs. for cattle.

Pulping Machines.—Farmers are not agreed concerning the amount of advantage derivable from the reduction of root-food to a softened state. In reference to potatoes, it has been found worth while to steam them for pig food; and even diseased potatoes, if not very far decayed, by being thus treated, may be rendered good victuals to be stored up for months. The pulping of turnips enables the root to be incorporated with other nutritious articles of food. Pulping and Steaming machines now occupy a place in all the exhibitions of Agricultural Implements.

Land Draining.

Drain-tile Machines.—In strictness, the preparation of ground for farming purposes ought to receive priority of notice, before the processes of agriculture. But in truth the two subjects are widely distinct. Draining is a part of the civil engineer's labours, requiring the application of numerous principles having little direct relation to vegetable culture. It is an answer to the problem—how to remove from land a too great abundance of moisture; in the same way that irrigation is the process of imparting to land an additional quantity of moisture.

Draining-ploughs.—Somewhat more closely connected with the farmer's operations, but nevertheless, requiring the aid of other persons, is the use of the very singular draining-plough; by which one machine not only digs a drain, but also places a layer of draining-pipes in it.

It will be convenient, therefore, to refer to Drain-pipes and Tiles, for an account of the ingenious machines by which clay is so fashioned as to be available for these purposes; to Draining, for a description of the modes of applying these pipes; and to Irrigation, for a notice of the modes of supplying water to the soil for the purposes of agriculture.

Application of Steam Power.

One of the most important questions now pressing on the attention of agriculturists is—to what extent may steam-power profitably supersede horse-power and manual labour? Steam-engines may be applied to work the machines of the barn and threshing-floor, such as threshing machines, winnowing and dressing machines, and the like; or they may be applied to the operations of the land, such as ploughing, harrowing, &c. All agree that these things can be done; but the problem waiting for solution is, whether they can be done profitably. Under the headings Drill, Plough, &c., will be found details relating to this matter; but it seems desirable to make a few general observations on the subject in this place.

All agricultural steam-engines must ultimately resolve themselves into one or other of five kinds—fixed engines, to work machines contiguous to them; locomotive engines, to work a fixed machine; fixed engines, working locomotive machines by means of a travelling strap or rope; locomotive engines, carrying their own railway with them over the surface of a field; and locomotive engines, travelling on lines of rail regularly laid down on the field.

With regard to the first of these kinds; it is evident that any mechanism which is made to rotate may have its rotation given by a steam-engine as well as by a horse moving in a circle, or by a man turning a handle or wielding a flail. We may, therefore, at once refer to the special articles for instances: simply stating, that steam power is becoming more and more largely employed every year in performing the operations of the barn and the mill. Fixed steam-engines have been in use many years in Northumberland and East Lothian for threshing and other barn operations.

The Royal Agricultural Society has been honourably distinguished by the zeal with which it has encouraged improvements in this direction. It propounded the question, whether moveable steam-engines would not be better than fixed engines for barn as well as field purposes. It assigned three reasons for answering this question in the affirmative. 1st. That if a farm be very large, it will be greater economy to wheel a locomotive steam-engine to different parts, than to employ horses and men in bringing all the corn in the straw to one point, and again carrying out the dung to a distance (perhaps) of two or three miles. 2nd. If a farm be of small or moderate size, it will not support the expense of a fixed steam-engine; whereas, a portable engine may be available for two or three farms, at a fair ratio of expense for each. 3rd. Although threshing can only be performed under cover in barns by fixed engines, it is perfectly feasible in the open air by a locomotive engine—a plan healthier and more expeditious for the labourers, and rendering practicable a diminution in the number of farm buildings requiring to be constructed by the landlord. The Great Exhibition of 1851 brought forward the skill of many makers, such as Hornsby, Tuxford, Clayton, Barrett, Hensman, Bullin, Roe, Ransome, and Garrett; but it also showed that the invention was still in its infancy, for the worst specimen consumed three times more coal than the best for the same amount of work. Of thirteen locomotive agricultural steam-engines put to trial, the nominal horse-power varied from 4 to 9; the time of getting up steam, 28 to 83 minutes; the coal used in getting up steam, 25 lbs. to 75 lbs.; the coal burned per horse-power per hour, 6·79 lbs. to 25·80 lbs. Mr. Locke, the eminent engineer, in reporting on these trials, said:—"If I might be permitted to suggest a little advice to the makers of these engines, I would beg of them to attend more to the proportions of the various working parts, and less to external ornament. There is a want of good proportions in several of the engines; and this to a mechanic or an economical farmer is of more importance than a profusion of brass." Taking the experience of 1851 as a basis, the engine-makers have every year endeavoured to introduce improvements. At the Carlisle meeting of the Agricultural Society, in 1855, a marked advance was observable in the locomotives for farm purposes. The maximum consumption of coal per horse-power per hour was 10 lbs., while the minimum was as low as 3·7 lbs. It was found, however, that some of the engines had been built expressly to win the Society's prizes and commendations, and that more attention was needed to the rough and every-day qualities required for practical farming. By the year 1857 it had become a practice not at all unusual to make one steam-engine, under the charge of an intelligent farm labourer, perform all the operations of setting in motion threshing and winnowing machines, cutting chaff or roots, crushing oats, grinding corn, pulping mangold-wurzel, splitting beans, sawing wood, pumping water, and applying steam for steaming potatoes or roots. At the Salisbury meeting in that year, it was announced that Messrs. Clayton and Shuttleworth were making and selling agricultural steam-engines at the rate of five hundred per annum; and by the close of 1858 they had made several thousands, mostly for export to foreign countries, where English agricultural machines are now eagerly sought for.

We have, lastly, to notice the most comprehensive system ever yet proposed, for applying steam-power to agriculture; a system only yet tried on a small scale, awaiting the time when it can be put to better tests. It is called the 'Guideway Steam Agriculture;' and it was fully described by its inventor, Mr. Halkett, at a meeting of the Society of Arts, on the 8th of December, 1858. The subject had been introduced to the society, and also to the Royal Agricultural Society, in 1857; but certain additions and improvements were made during 1858. The inventor regards his system as advantageous, not so much in the reduced cost of field operations, as in the increase of crops resulting therefrom. The principle consists in the laying down of permanent rails on the field, and the travelling of all the machines along those rails. The rails are laid in parallel lines on a very broad gauge. The ploughing, scarifying, sowing, hoeing, and reaping instruments are attached beneath a travelling carriage having locomotion given to it by steam power. The gauge has been tried at thirty feet; but the inventor sees no obstacle to the use of one as great as fifty feet. At right angles to the rails, along one side of the field, are other rails on a lower level, with very low carriages or trucks, the upper surface of which is on a level with the field rails; upon this truck the cultivating machinery moves, and is transferred sideways from one set of rails to another, or home to the steading. It is a sort of apparatus like that which is much in use on the Great Western Railway for transferring carriages from one pair of rails to another. This cross-railway Mr. Halkett calls the headland railway, on which the headland truck works. Three modes of laying down the rails are suggested. The first, for clay districts, consists in laying angularly-topped iron rails on a support of hard-baked bricks, which are themselves supported by a ballasting of burnt clay or concrete; this form requires that the tires of the wheels should have angular grooves to fit upon the rails. The second, for wood districts, is a cheap mode of laying down flat-surfaced creasoted wooden rails, on wood sleepers. The third, for market gardens and other high-rented land, consists in resting the rails on small posts or piles, in order to economise space. One reason for the great breadth of gauge is that as little land as possible may be occupied by the rails and their supports. As none of the machines could travel along the rails at a greater speed than two or three miles an hour, minute accuracy of gauge and of motion would not be so necessary as upon an ordinary railway.

Such being, in few words, the arrangement of the rails and carriages, the steam culture is as follows:—The steam cultivator, a system of ploughs, is driven by two locomotive engines, placed at the extreme ends or sides, which are geared together by intermediate shafts. The cultivator has two sets of ploughs, working in opposite directions, and each in use during one particular direction of movement only; the other set being meanwhile raised by racks and pinions. The inventor states that 25 acres can thus be ploughed in a day of twelve hours. The land having been ploughed up, a 'comminutor' takes the place of the 'cultivator,' being, like it, moved by locomotives; it is something like the Norwegian harrow, but revolves at a high velocity, and its tines or spikes break up the soil to a fine condition. The clod-crushing, the hoeing, the harrowing, the manure depositing, the water distributing, the reaping, and other field operations, are done by attaching the requisite machines or implements to the travelling carriage.

The advantages to be expected by the adoption of this system are insisted on by Mr. Halkett in a variety of ways. The great advances which have been made by Fowler, Boydell, and other implement-makers, in ploughing and breaking up land by steam, have schooled the mind to the possibility of the same power being eligible for use in the field, and have prepared agriculturists to expect a system that shall perform more than one operation. The system is applicable both to extensive holdings and to smaller farms, by modifying the amount of power to be applied. As to the space robbed from the field by the rails and ballasting, the inventor contends that, even if greater than it is, it would still be less than the open furrows between ridges; and also that no farm-roads would be wanted in the field, seeing that the guideway machines convey everything to and from the field. As the machines can be worked nearly as well in the dark as in the light, they might be made to do double duty in the twenty-four hours during seasons of exigency, by a relay of a few hands. When once the soil has been brought to a high condition, it may easily be kept so; for the whole weight of the machinery, engines, and implements rests upon the rails; nothing touches the soil except the implements in operation; no horses need stamp the ground with their iron-shod feet; and the footprints of the guide and the ploughman need never be seen pugging the clay, and treading into a solid clod that which has been reduced to the fineness of garden-mould. At present, the weeding, earthing-up, hoeing, and loosening of the earth among young crops are difficult to perform with the requisite care except by hand; but the guideway implements can be adjusted with great nicety, so as to travel at the requisite proximity to the rows at all times during the growth of the plant. Besides the machinery which carries the engines and implements, there are other guideway arrangements, equal in width from rail to rail, but smaller and lighter, for carrying water, manure, and the gathered crops; and the sprinkling of water and liquid manure can be effected nearly in the same way as by the water-drill. When manual labour is required for the purpose of weeding, transplanting, or any other light work, the labourers are conveyed to the spot by means of the trucks, upon which they sit or stand while the work is being performed, or while the crop is being transferred from the ground to the truck. The trucks for this purpose might be drawn by horse-power or by manual labour, if preferred. Where the side of a field is crooked, the crooked part may easily be fenced off and used for ordinary cultivation. Where roads or lanes intervene between different fields, a level crossing on moveable rails would enable machinery to pass from field to field. If a farm abuts on a railway, it may be made to communicate with it; by this means the produce may be sent to populous towns without once leaving the rails; manure may be brought from the towns to the fields at a very small expense; and marl, clay, or sand, may be brought cheaply from distant places. The smaller system of cultivation, for the light operations of a farm, or for the total cultivation of a market-garden, might be worked by one small steam locomotive instead of two. Mr. Halkett has sketched the appearance of his apparatus when provided with all the implements for drilling corn, drilling seeds between the rows of plants, hoeing, rolling, surface watering, watering in rows, underground watering between rows, carrying crops, carrying water, weeding, transplanting, dibbling, and cross-hoeing, for the light operations of a farm, or for market-gardens,—of course not all working at once, but showing the mode of arrangement for each. The inventor believes that the guideway system would be profitably employed in the West Indies, for ploughing, earthing the sugar crops, hoeing, carting the canes from the field, and other operations in which slave labour is now found to be really very costly.

In a discussion which followed the reading of Mr. Halkett's paper at the Society of Arts, very conflicting opinions were expressed concerning the advantages of his new guideway system of steam culture. It was contended by some of the members, that the machines would cost more than was stated; that the system was not well adapted for other than very large farms, with large rectangular fields; that the system would not be workable except under a custom of long leases of farms, which would induce the farmers to invest the requisite capital; that the curves, and twists, and corners of a field would always be a source of perplexity to the farmers under this system; that the profits could not be so large as had been stated; that, even if large, there must first be a very heavy expenditure of capital, from which most farmers would shrink; that fields would require a good deal of levelling to bring out all the excellences of the system; and that the rails *would spoil the fields for fox-hunting!* On the other hand, it was contended that Mr. Halkett's system contained the germ of that which may greatly advance the science and art of agriculture in a future day. The commercial difficulty in reference to the heaviness of the first cost was generally regarded as being more serious than any mechanical difficulties, which it was believed might easily be overcome. A further notice of various methods adapted to cultivate the land by steam will be found in the article ARABLE LAND.

Whatever may be the relative merits of different modes of applying steam-power to agricultural purposes, it is evident that this modern invention is, in conjunction with other improvements, working a great revolution in farming operations. Mr. Pusey, in reporting on this subject, as Chairman of the Exhibition Jury, in 1851, made the following estimate:—That by using lighter ploughs, cultivators that lessen the necessity for ploughing, drills that economise both seed and moving-power, horse-hoes instead of hand-hoes, varied manures instead of manures of a few kinds, reaping-machines instead of sickles, well-constructed carts instead of clumsy wagons, fixed and portable steam-engines, steam threshing- and winnowing-machines, turnip- and chaff-cutters, drain-tile machines, and draining-ploughs, *there had been effected in twelve years a saving of one-half the former outlay in cultivating a definite amount of crop.* It had been rendered further demonstrable that machinery had given comparative *certainty* to agriculture, by enabling many of the operations, in doubtful or unfavourable weather, to be done with quickness, which could hardly have been done at all by the hand method. Mr. Evelyn Denison (now, in 1859, Speaker of the House of Commons) prepared a Report on the Agricultural Implements displayed at the Paris Exposition de l'Industrie in 1855, in which he endeavoured to estimate the material saving accruing from the use of machinery in agriculture. Mr. Sidney, at the close of 1857, gave a few figures intended to bring down the estimate to that year. In this last-named estimate, it was supposed that within six years—that is, since Mr. Pusey prepared the Great Exhibition report—the landowners of the United Kingdom had expended ten millions sterling in draining two million acres of land, on principles and with tools not known until 1845. Then, besides all the saving on the items already enumerated, there is that precious, though not easily-calculated advantage resulting from the economy of *time*, by employing machinery at full force during short intervals of fine weather.

AGRICULTURAL STATISTICS can scarcely be said to exist as yet in England. Notwithstanding the acknowledged importance of exact information as to the amount of our agricultural production and consumption, especially to farmers, and the interest that is taken in the subject, as shown by the attention to the Mark Lane reports, which are little better than ingenious guesses, no steps have yet been taken to insure a correct estimate of the expected amount of the incoming crops, and the state of live stock. Such estimates as are made are derived from individual instances, than which nothing can be more fallacious. The great differences in cost, cultivation, and even of climate in England, make the application of the doctrine of *averages* almost more indispensable in agriculture than in any other trade. It is by the accumulation of individual parts that we arrive at something like a *law*. A law prevails in agriculture as in everything else, and the more any subject has the appearance of chance, the more necessary it is that the experiences should be registered, in order to arrive at the law expressed by an average. The inconvenience and loss occasioned by the absence of statistical returns has been often felt. After the harvest of 1846, the average price of corn for six weeks, from the middle of August to the end of September, was 48*s*. 2*d*., the lowest price being 45*s*. 1*d*. In October, the price improved; but in November it again fell to 50*s*. But as soon as the new year had begun, symptoms of scarcity manifested themselves, and the wheat of that same harvest, notwithstanding the importation of four millions and a half of quarters, reached the price of 102*s*. 5*d*. per quarter. In this case, a knowledge of the produce of the harvest would have saved the farmer from the sacrifice of his property at the beginning; it would have saved the country from a great loss in the price of the foreign corn imported, occasioned by a sudden rush into the market for large supplies; it would have probably saved considerable waste of food during the period when it was improperly cheap; it would have saved inconvenience to the foreigners in whose markets our purchases inevitably increased the price of wheat; and the gains of the merely speculating corn-dealers would have been saved to the community.

The desirableness of some knowledge on so important a subject has led many individuals to form, from the best available sources, general estimates, but the discrepancies show the unreliability of such estimates for any practical purpose. Some endeavoured to arrive at it by taking the acreage of the kingdom, the proportion supposed to be cultivated, and the probable amount of produce per acre. Gregory King, who wrote in 1685, was among the earliest. He estimated England and Wales to contain 39,000,000 acres, of which he supposed half to be uncultivated. Davenant, Grew, Templeman, Sir William Petty, Arthur Young, Dr. Beeke, Mr. M'Culloch, Mr. Porter, and others, formed estimates varying from 31,648,000 acres, to 46,916,000 acres, which was the estimate of Arthur Young, and was adopted by Mr. Pitt in his calculations for the probable amount of the Income Tax. In the census of 1851, the area is stated at 37,324,915 acres, which was very near the estimate of Dr. Beeke, who gave it as 38,498,572. Others, again, have endeavoured to ascertain the consumption by multiplying that of each individual by the number of the population, but here they differ materially, varying from 6 bushels to 8 bushels for each individual, an unsatisfactory difference of one third. We will now enumerate what measures have been taken in providing statistics by the government.

What are called the *corn averages*, are entries or tables originally intended to regulate the duty on corn; but if modified and improved, they might be made an auxiliary to agricultural statistics. For a century previous to the year 1851, such returns were collected from the principal seaports of twelve maritime counties—entirely in relation to the imposition of duty on foreign corn; the collector of the returns was appointed by the magistrates of the town or borough in which the return was made, but his salary was paid by the government. In 1821 a change was made. The averages were ordered to be collected from 120 large market-towns in England and Wales. Every corn-merchant, miller, baker, and maltster, was ordered to make weekly returns to the inspector. The inspector provided a place for the reception of these returns; he posted up in some convenient locality the gross weekly returns, with the average price of each description of grain sold in the preceding seven days. These averages were then forwarded to the Comptroller of Corn Returns, in London, who added up all the gross amounts from all the inspectors, and struck a six-weeks' average for the whole kingdom—which average regulated the duties on the admission of foreign corn for home consumption. When the 'sliding-scale' came into operation, there were several instances of the averages being tampered with, in London and some of the outports, by false returns; this was done by fraudulent persons, with a view of lowering the rates of duties by fictitious sales of large quantities of corn; thus swelling the quantity returned, raising the prices, and lowering the duty. In 1842 a motive of economy, whether wise or not, led to the appointment of excisemen, without any increase of salary, in place of inspectors, as the latter might die off, for taking the corn averages; and the returns are believed to have suffered in accuracy from this change. When the corn laws were repealed, further changes were made; the corn averages ceased to be as valuable as before in respect to fiscal regulations; but they remained important in connection with the commutation of tithes; and it is now considered that they might render useful aid to agricultural statists. The list of towns whence the returns are made has been largely increased; in all the towns thus added, excisemen have been appointed instead of inspectors.

These returns, it is evident, showed nothing beyond the average prices. In 1832 the attention of the government was directed to the attainment of more satisfactory results. In the previous year, a statistical inquiry had been made by a committee of the magistracy of Norfolk, respecting the acreage and crops of that county. The committee addressed circulars to 680 parishes; but 254 of these declined to answer the questions submitted to them, and the committee had no other resource than to infer from the 426 affirmative to the 254 negatives. Still, though imperfect, the result was useful as a beginning; and in 1832, when the Statistical Department of the Board of Trade was established, Lord Auckland saw the importance and necessity of obtaining correct agricultural statistics. Nothing was effected, however, until 1836, when the Board of Trade resolved to make a small experiment of its own. Circulars were sent to the clergymen of 126 parishes in Bedfordshire, enclosing schedules of the returns required, and asking for co-operation. This experiment was a most signal failure; for out of 126 parishes applied to, only 27 returned any answer. It was a time when the clergy and the high tory party distrusted the suspected radicalism of most new government projects, and it was on that account an unfortunate period in which to make the attempt. Eight years passed over; when, in 1844, Mr. Gladstone, at that time President of the Board of Trade, stated in the House of Commons that the subject was under his consideration. The Board of Trade, the Home Office, and the Poor Law Board, next had a long correspondence in reference to the question, whether the last named of these three might undertake the management of a system of national agricultural statistics; and it appears to have been decided that, as constituted at the time, the Poor Law Board could not adequately fulfil this duty. In 1845 the Board of Trade resolved to make another attempt, or rather three small attempts in the three kingdoms—North Hants in England, Mid-Lothian in Scotland, and Bailieborough Union in Ireland. The Irish inquiry was made by a private individual, and was satisfactory; the Scotch inquiry was managed by the schoolmasters of the respective parishes, and was equally successful; but the English inquiry was an utter and disheartening failure. The Board of Trade, in this last-mentioned case, addressed communications to the Board of Guardians of the different Unions; while the Poor Law Commissioners backed the application, by requesting the Board to employ their own paid officers to induce the occupiers of land to fill up the schedules that were sent to them. The result was almost *nil*; scarcely any returns were obtained; and a strong impression was left that nothing less than compulsory powers would be available for obtaining the desired statistics.

The next attempt was made in 1847, when Mr. Milner Gibson, Vice-President of the Board of Trade, brought into Parliament a 'Bill to make Provision for the Collection of Agricultural Statistics in England and Wales.' By the provisions of that Bill, the duty of obtaining the statistical information was to devolve upon the Registrar-General of Births, Deaths, and Marriages; the superintendent registrars throughout the kingdom were to be charged with the appointment of "agricultural enumerators" in their respective districts; the enumerators were to prepare lists of all the occupiers of land exceeding three acres, to send specified blank forms to those occupiers, and to collect those blank forms after an interval of fourteen days filled up with the several entries of particulars. This being done, the enumerators were to classify the returns, and construct general tables from them. These tables were to be transmitted to the superintendent registrars, by them to the Registrar-General, and by him to the Board of Trade. These returns and tables were to apply to the month of June in each year. The Bill was read a first time; but as the public had not yet learned to feel much interest in the subject, and as various party questions were then on the *tapis*, the Bill shared the fate of many others, and fell to the ground.

In 1854, an attempt was made to obtain complete statistical details through the machinery of the Poor Law Board. The selection was unfortunate, for the impression was instantly received that the returns would lead to additional assessment, and no explanation availed to remove that belief. In addition it was generally feared that such returns would be used against the farmers by their landlords in order to raise their rents, they, in very few cases, holding their farms upon lease. The West Riding of Yorkshire was the only division from which a complete return was procured. In all the other counties the returns were so incomplete as to be useless. Many Unions refused altogether, alleging that their officers had sufficient other duties to perform, and in some Unions up to a proportion of one half, where the guardians had consented, many parishes made no returns. In 1855, a Committee of the House of Lords was appointed on the subject, before which numerous witnesses were examined, and among them most of the Poor Law Inspectors. Notwithstanding their ill-success, and the many admissions they were compelled to make of the continued opposition that would be offered to the investigation of a farmer's affairs by Poor Law officials, the most of them represented that all that was required was a compulsory Act; and accordingly the Lords' Committee embodied a series of resolutions in their report, recommending the government to introduce a Bill into parliament for two returns a year, in July and November, to be carried out by the same machinery. The government however have not yet adopted the recommendation.

Under these disadvantages we will endeavour to give a few of such statistics relating to agriculture as rest upon sure bases. It is quite certain that a rapidly increasing population must have been fed, and that the means of feeding them can only arise from land not previously cultivated, from importation, or from improved cultivation. The following figures will give some notion of what has been effected in each division; unfortunately however, though the inclosures and population apply only to England and Wales, there is no separating the application of the imported wheat from that consumed in Scotland. The amount is no doubt very small, for wheaten bread was not generally used in that part of the kingdom in the early periods recorded; and from the vast improvement in cultivation during the latter portions of them, there is probably more than sufficient corn produced in Scotland to supply the population.

	Acres inclosed.	Qrs. imp.	Increase of Pop.
1800 to 1810	1,657,980	6,009,458	2,173,589
1810 to 1820	1,400,930	4,585,780	945,588
1820 to 1830	340,380	5,349,927	1,110,793
1830 to 1840	236,070	9,076,379	2,032,525
1840 to 1850	369,127	23,298,353	2,048,573

The increase of population is taken from between each of the decennial censuses commencing with 1801. The inclosures of course must necessarily decrease, and the best lands will have probably been among the earliest inclosed. Since 1846 the inclosures of commons have been conducted by commissioners, and are passed in Acts in groups, in which the acreage is only occasionally stated. The amount on the whole since 1850 does not average more than a few thousand annually, while the population has increased in about the same proportion as in the previous decennaries. The result is that somewhat above four million of acres have been acquired for the support of upwards of eight millions and a-half of additional mouths. In 1851 there were imported 3,833,636 qrs. of foreign wheat, and 5,363,478 cwt. of wheat flour; in 1852, 3,068,892 qrs. of wheat and 3,889,583 cwt. of flour; in 1853, 4,949,314 qrs. of wheat and 4,646,400 cwt. of flour; in 1854, 3,431,227 qrs. of wheat and 3,646,505 cwt. of flour; in 1855, 2,667,702 qrs. of wheat, and 1,904,224 cwt. of flour; and in 1856, 4,072,833 qrs. of wheat, and 3,970,100 cwt. of flour. During the whole of this period the price of wheat has on the whole decreased. During the long war with France, from 1800 to 1815 inclusive, the average price per quarter was 84*s.* 9*d.*; from 1816 to 1820, it was 78*s.* 4*d.*; from 1821 to 1830, it was 58*s.* 3*d.*; from 1831 to 1840, it was 57*s.*; from 1841 to 1850, it was 56*s.*; in 1851, it was 38*s.* 6*d.*; in 1852, 40*s.* 5*d.*; in 1853, 52*s.* 11*d.*; in 1854, 73*s.*; in 1855, 74*s.* 9*d.*; in 1856, 69*s.*; and in 1857, the highest point reached was 63*s.* in July, and the lowest in December 45*s.* 3*d.* In 1858, the price varied only between 49*s.* and 43*s.* during the year.

All the statistical returns obtained by government have a fiscal basis. The only real agricultural statistics we possess are those for hops, of which we know every cultivated acre and every pound of produce; and barley, of every bushel of as much as is made into malt. These we owe to the duty; but when, as in the case of live stock, the duty is discontinued, no account is taken by it even of importations, though the Board of Trade in their monthly returns give the number imported as obtained from other sources. The following is the return so given for the month ending November 30th, 1857, and for the whole of the year 1857.

		Month.	Year.
Oxen and bulls, and cows	number	9892	65,648
Calves	,,	2738	27,315
Sheep and lambs	,,	25,270	177,207
Swine and hogs	,,	1459	10,677
Bark	cwts.	28,686	381,243
Wheat	qrs.	456,804	3,437,957
Barley	,,	100,597	1,701,470
Oats	,,	197,296	1,710,299
Peas	,,	14,831	159,899
Beans	,,	36,368	305,775

		Month.	Year.
Indian corn or maize	qrs.	152,770	1,150,783
Wheatmeal or flour	cwts.	267,160	2,178,148
Indian corn meal	,,	58	1092
Hemp, jute, &c.	,,	108,779	1,439,622
Guano	tons	43,289	288,362
Oilseed cakes	,,	10,283	99.265
Potatoes	cwts.	215,386	955,057
Hops	,,	1857	18,712
Bacon and hams	,,	5331	366,934
Beef, salt	,,	5561	150,940
Pork, salt	,,	4433	88,732
Eggs	number	6,645,000	127,039,600
Butter	cwts.	31,189	442,837
Cheese	,,	33,882	394,749
Lard	,,	54	182,860
Clover seed	,,	8823	171,585
Flax seed and linseed	qrs.	164,734	1,051,113
Rape seed	,,	21,363	220,495
Timber of various sorts from British possessions and Foreign	loads	282,184	2,616,088
Wool, from British possessions and Foreign	lbs.	11,680,071	127,390,885

These returns apply however to the whole of the United Kingdom. The remainder of the estimates for England rest only upon probabilities. Thus, in the Journal of the Royal Society of Agriculture for 1856, the number of sheep in England and Wales is estimated at 27,000,000, worth upon an average 30*s.* per head. About 10,000,000 are annually slaughtered for food, producing 800,000,000 of lbs. of mutton, which, at 6*d.* per lb., amounts to 20,000,000*l.*; and calculating the weight of each fleece at 4½ lbs., 121,500,000 lbs. of wool is obtained, worth at 1*s.* 3*d.* per lb. nearly 8,000,000*l.* The number of cattle has been estimated at 5,620,000, and that of swine at about 5,000,000. The number of horses is given by Mr. M'Culloch in 1847, and they have probably not greatly increased since, as 1,500,000, the value of which he estimates at from 18,000,000*l.* to 22,500,000*l.* Such statements bear upon their faces evident marks of uncertainty, while the trouble any individual must have taken to procure materials even for a guess, shows the call there has been for this species of information.

In Scotland, where leases are, and have long been, almost universal, and where a less objectionable machinery was employed, statistical returns were much more easily obtained. Tenants there had indeed been long accustomed to the term, which some have asserted had no little influence in affrighting the farmers of England. In 1800, Sir John Sinclair had, with the assistance of the parochial ministers and others, produced a 'Statistical Account of Scotland,' giving in detail the state of every parish. This had been re-produced between 1834 and 1845, in so complete though bulky a form, and the agricultural improvements had been so great, as to justify the committee of ministers who had carried it through, in saying, "They now present not merely a new statistical account, but in a great measure the statistical account of a new country." In 1847 the members of the Highland and Agricultural Society of Scotland, by whom agricultural improvement has been greatly promoted, felt the need of statistics, and by means of their secretary, Mr. Maxwell Hall, set about obtaining them. They memorialised Sir George Grey on the subject, and were desired to communicate a scheme, which was done, but without result. In 1852 they again memorialised the Home Department, offering their assistance if any project were legalised, but again without anything being effected. In 1853 the government allowed the sum of 5000*l.* to make the experiment, and Mr. Maxwell Hall determined to endeavour to obtain the returns, though without any legal support. Complete returns were obtained for three counties, Haddington, Roxburgh, and Sutherland. In 1854 he travelled through a great part of Scotland requesting the assistance of farmers; he succeeded in removing their objections, and convincing them of the advantages; and by means of local branches of the parent institution succeeded in procuring complete returns for the kingdom. These have been continued annually up to 1857, since which, owing to an unfortunate misunderstanding, they have been discontinued. Though there have been a few omissions they are the most complete in their details of any yet known. Though the absence of similar returns of England deprives them of much of their value, they are still, conjoined with those of Ireland, of great importance. We give an abstract of the returns for 1856 and 1857. We may premise that the returns are from holders paying a yearly rent of 10*l.* and upwards (exclusive of tenants of woods, villas, feuars, householders and the like) in all the counties of Scotland except Argyle, Inverness, Ross and Cromarty, Sutherland, and that part of Bute which lies in Arran, in both years, and in Caithness, Sutherland, and Orkney, in 1856, where the returns are only from holders paying a rent of 20*l.* and upwards. Woods, sheep-walks, houses, roads, and waste, are omitted in the calculation.

In 1856 the number of occupants was 42,919; in 1857 there were 43,432. The number of acres under rotation of crop was 3,545,191 in 1856; of which, of wheat there were 263,328, of barley 165,738, of oats 918,644, of rye 4020, of bere 15,368, of beans 40,470, of peas 4817, of vetches 18,231, of turnips 460,131, of potatoes 149,351, of mangold 3531, of carrots 1532, of cabbages 1485, of rape 1407, of flax 2723, of turnip seed 1759, other crops 795, bare fallow 14,464, and grass and hay in rotation 1,475,775, which leaves 1602 of the stated total unaccounted for. The produce was 7,270,952 bushels of wheat, 5,581,970 of barley, 31,966,381 of oats, 6,540,267 tons of turnips, and 413,800 tons of potatoes. In 1857 the number of acres under crop was 3,556,572, of which there were of wheat 223,152, of barley 198,387, of oats 938,613, of rye 5989, of bere 21,607, of beans 39,186, of peas 3687, of vetches 18,418, of turnips 476,691, of potatoes 139,819, of mangold 2803, of carrots 1401, of cabbages 1704, of rape 2032, of flax 1534, of turnip seed 2576, of other crops 577, of bare fallow 18,582, and of grass and hay in rotation 1,459,805, an excess of 989 acres over the stated total. The produce was 6,154,986 bushels of wheat, 6,494,534 of barley, 32,750,763 of oats, 6,690,109 tons of turnips, and 430,468 tons of potatoes. In 1856 the total number of horses was 179,853, of milch cows 209,960, of other cattle 473,384, of calves 197,709, of sheep and lambs 5,816,560, of swine 128,924. In 1857 the numbers were, of horses 185,409, of milch cows 303,912, of calves 195,198, of sheep and lambs 5,683,168, and of swine 140,354. In this account the horses, cows, and swine kept in towns are not included; and it is estimated that above 300,000 head of stock, and upwards of 200,000 acres of tillage are held by occupants not in these returns. Fife and Haddington show the greatest proportional acreage in wheat and in white crops generally, and Aberdeen and Argyle the greatest in turnips; those counties also possessing the greatest number of live stock.

In Ireland, where the interest felt might have been supposed to be less, statistical returns have been obtained in an excellent form, and with no opposition. The task of gathering the returns was confided to the constabulary in 1852, and they have been continued annually since. We append the return of 1857:—In that year the returns show that there were 5,860,089 acres under crop, being an increase of 106,542 acres over the quantity in 1856. Of these 562,581 acres were in wheat, 1,978,878 in oats, 246,257 in barley, beans, peas, &c., showing a small increase of cereal crops generally, but a decrease on oats of 58,559 acres. On green crops there was a general increase of 45,637 acres, potatoes occupying 1,146,920 acres, an increase of 42,216 acres, and flax had decreased from 106,311 acres in 1856 to 98,074 acres in 1857; and turnips had decreased 4,487 acres. Meadow and clover had increased from 1,302,787 acres to 1,369,421 acres.

The produce of the 5,753,681 acres in cultivation in 1856 had been 2,738,163 barrels of wheat of 20 stone each; 14,778,045 barrels of oats of 14 stone each; 1,367,453 barrels of barley of 16 stone each; 50,709 barrels of bere of 16 stone; 72,165 barrels of rye of 20 stone; 431,561 bushels of beans and peas; 35,268,345 barrels of potatoes of 20 stone each; 4,581,172 tons of turnips; 287,838 tons of mangold wurzel; 332,650 tons of cabbages; 3,006,553 stones (of 14 lbs.) of flax; and 2,492,732 tons of hay. The total number of holders of land was 592,489; of whom 36,474 held not more than 1 acre; 82,035 not more than 5 acres; 179,931 not more than 15 acres; 138,424 not more than 30; 71,156 not more than 50; 53,279 not more than 100; 21,292 not more than 200; 8243 not more than 500; and only 1655 held upwards of 500 acres.

Live stock, except sheep, had increased remarkably. The number of horses was 600,693, an increase of 27,285; the number of cattle 3,618,544, an increase of 30,686; the number of sheep 3,448,676, a decrease of 245,618. Pigs numbered 1,252,152, an increase of 333,627.

Road contractors in Ulster are required to keep the roadsides and fences free from weeds, and surveyors in the other provinces are recommended to obtain authority from grand juries, &c., to enforce in them similar regulations.

Most foreign countries have found the necessity of having statistical returns of their agricultural produce. Austria, Prussia, France, Denmark, Hungary, Belgium, and the United States of America, have all such returns more or less perfect, among which those of Belgium take a high rank, and are nearly equal to those of Scotland. In France these duties devolve upon a department of the minister of commerce and agriculture. The management of the royal flocks, veterinary schools, and the royal studs; the distribution of premiums in agriculture; the organisation and presidency of the superior and special councils of agriculture, are comprised in the duties of this ministerial department. The councils-general of agriculture, &c. in each department of France collect the agricultural statistics from each commune; and the quantity of land sown with each description of grain, the produce, and the quantity of live stock for the whole of the kingdom, are accurately known and published by the minister of commerce and agriculture. In Belgium these facts are ascertained periodically, but not every year. In the United States of North America, at the decennial census, an attempt is made to ascertain the number of each description of live stock, including poultry; the produce of cereal grains, and of various crops; the quantity of dairy, orchard, and garden produce, &c., in each State. There are twenty-nine heads of this branch of inquiry. The only countries in Europe which do not possess statistical accounts of their agriculture founded on official documents are England and the Netherlands. On the same principle that a census of the population of a country is useful, it must be useful to have an account of its productive resources. The absence of official information is supplied by estimates of a conjectural character, founded at best only on local and partial observation. In France it was positively ascertained that the average produce of wheat for the whole kingdom is under

14 bushels per acre. In England it is known that a large crop of wheat is about 40 bushels per acre, and that a small one is about 20 bushels. The usual conjecture is, that the average produce of the kingdom in years of fair crops is about 28 bushels, but the total superficies sown with wheat or any other grain, and the total quantity of the produce, are matters simply of conjecture. Such statistics for the whole of a kingdom are highly valuable for the guidance of the inhabitants of that kingdom; but if we possessed them for the whole of the civilised world, what are called the chances of agriculture would probably be reduced to a certainty, and the price of food would remain with little or no variation. It may be added that the most trustworthy groundwork of conjecture on this subject is furnished by the Government inquiry in 1854, to which allusion has already been made; and which, though confined to eleven counties, namely, Hampshire, Wiltshire, Leicestershire, Norfolk, Suffolk, Berkshire, Worcestershire, Brecknock, Salop, Denbigh, and Yorkshire (East Riding), was yet sufficiently wide and sufficiently representative of the whole country to justify an estimate upon them of the total acreage of England and Wales. The following are the totals thus estimated. Total statute acres, 37,324,915, namely, wheat, 3,807,846; barley, 2,667,776; oats, 1,302,782; rye, 73,731; beans and peas, 698,188; vetches, 218,551; turnips, 2,267,200; mangold wurzel, 177,263; carrots, 12,638; potatoes, 192,287; flax, 10,156; hops, 18,976; osiers, 1,079; other crops, such as cabbages, &c., 97,334; barefallow, 895,969; clover, lucerne, &c., 2,820,066. The total under cultivation thus appears to be 15,261,842 acres. Under grass we have as follows,—permanent pastures, 8,874,946 acres; irrigated meadows, 1,292,329; sheepwalks and downs, 2,224,862; or in all, 12,392,137 acres. In addition to this there are 976,197 acres in gardens, roads, fences, houses, &c.; 786,658 acres in waste attached to farms; 1,697,362 acres in woods and plantations; 459,447 acres in commons belonging to parishes; 459,447 acres in holdings of less than 2 acres each; and 3,814,108 acres unaccounted for; making in all the beforesaid total of 37,324,915 acres.

Whenever the eleven counties are not in the aggregate truly representative, on the average, of the whole country, then it is plain that these figures must fail even of that imperfect accuracy which the partial returns for these eleven counties possess; and it is plain that in some of the particulars above specified no great confidence can be placed. The irrigated meadow land of England is, for instance, not nearly one-seventh or one-eighth of the ordinary permanent pasture as it is above represented to be.

The live stock of the country, estimated in the same way, is enumerated as follows:—horses, 1,050,931; colts, 258,079; milch cows, 1,376,703; calves, 707,192; other cattle, including working oxen, 1,339,270; rams, 244,106; ewes, 7,299,915; lambs, 6,987,982; other sheep, 4,159,085; swine, 2,363,724.

The total number of schedules issued in the eleven counties for the purpose of the inquiry was 118,287, and this represents the number of occupying tenant farmers in those counties. This number extended proportionately over the whole country would be 570,137.

These figures are given as the only approximation which we have to the agricultural statistics of England and Wales; though how far they must be from strict accuracy is sufficiently obvious. The inquiry in England did not extend, as it has done in Scotland and Ireland, to the produce of the country, but merely to the average of the crop, and the numbers of the live stock.

AGRICULTURE. Under various alphabetical heads will be found the theory and practice of husbandry. Any general observations are reserved for RURAL ECONOMY.

AGUE. Intermittent paludal fever is a disease belonging to the febrile group. Fevers are divided into three great classes. In the first the morbid phenomena that constitute the disease continue for a certain length of time; then they wholly disappear: after having been some time absent, they again recur, and this cessation and return of the phenomena alternate with one another for many times. The period that elapses between the cessation of the febrile phenomena and their recurrence, is called an intermission. Such fevers, then, as are attended with a cessation or intermission of the febrile symptoms for an observable space of time, are for this reason called *intermittent fevers* or *agues.* This is the first class. In the second class the febrile symptoms do not altogether disappear, but merely diminish in violence; they do not *intermit*, they only *remit;* for this reason this second class of fevers are called *remittent fevers.* In the third class, during the whole course of the disease, there is not only no retrocession of the symptoms, but no notable diminution of their violence. Such as the phenomena are when the fever is completely formed, such they continue to be with scarcely any variation until its close. For this reason this class of fevers is denominated *continued fevers.* [FEVER.]

The concourse and succession of phenomena which constitute a fever is called a paroxysm. An intermittent fever, or an ague, is therefore a fever consisting of a succession of paroxysms between each of which there is an intermission more or less complete.

The phenomena which constitute a paroxysm of fever are the following: The person is affected first with a loss of mental vigour, commonly indicated by inaptitude to attend to his usual avocations, or by dulness or confusion of mind. If not simultaneously with, very shortly after this mental debility there comes on a sense of physical weakness. The patient is languid, listless, disinclined to move, while every movement is performed with difficulty, and the effort to move is exhausting. The muscles or organs of motion are not merely weak—they are, at the same time, the seat of several uneasy sensations; the muscles of the extremities, and of the back especially, are affected with the sensation of soreness, as if they had been over-exercised, and this soon increases to decided pain, which is often very severe.

The next train of symptoms is ushered in by pallidness of the face and extremities: the features shrink; the bulk of the external parts is diminished; and the skin over the whole body is in a morbid state, as if drawn tight. Some degree of coldness is now felt, which at first is so slight as scarcely to be noticed, but at length the patient is fully conscious of a sensation of cold, which he commonly feels first in his back, but which thence extends over the whole body. This sensation of coldness increases until it becomes so severe as to produce a tremor in the limbs, amounting sometimes to trembling and shaking, and almost always producing distinct shivering.

From the first approach of the mental and physical languor, the pulse becomes weaker than in health. As the sense of cold comes on the weakness of the pulse is still greater, and it is at the same time always more frequent than natural; often irregular, and sometimes intermittent. The respiration also is shorter, feebler, and more frequent than in a state of health. The appetite fails; there is sometimes even an aversion to food; frequently the loss of appetite is succeeded by a sense of nausea and sickness, which occasionally increases to vomiting, and with the matter vomited there is, for the most part, a mixture of bile. From the commencement of the paroxysm there is generally some degree of thirst, which increases in urgency as the sensation of cold advances, being always proportioned to, and probably arising from, the dryness and clamminess of the mouth and fauces. Not the secretions of the mouth alone, but all the secretions of the system are diminished. The excretions also are lessened in quantity, and especially the urine, which is scanty and nearly colourless, and the alvine evacuations are usually altogether suppressed. Even in this stage, headache may come on, but it usually does *not* appear until the following.

The symptoms having continued for some time, at length disappear, and a remarkable change takes place in the character of those that succeed. The sensation of cold gives place to that of heat, and a temperature far greater than that of health prevails over the whole body. The face which had been pallid, now becomes flushed and red. The eyes which had been dull and heavy, are now more bright and glistening than natural. The features of the face and the other parts of the body recover their usual size, and become even more turgid. The pulse becomes more regular, strong, and full, the respiration fuller and more free, and the nausea and vomiting are less urgent: if before there were pain in the head, it now increases in severity; if there were none, it is now sure to come on, and while the sensibility is increased, the intellectual operations are more and more disordered.

By degrees these symptoms also pass away, and are succeeded by a different train. A moisture now breaks out first on the forehead, which by degrees extends over the whole body. As the perspiration flows, the heat abates; the pulse becomes slower and softer; the respiration more free; the nausea and vomiting cease; the thirst diminishes; the secretions and excretions are restored; most of the functions return to their ordinary state, and the patient is left comparatively free from disease, feeling only weak and exhausted.

Such are the phenomena that constitute a febrile paroxysm, and such is the order of their succession, and they obviously constitute three distinct states, or, as they are called, stages or fits; namely, the cold, the hot, and the sweating stage.

After one such paroxysm has remained for a certain length of time, it ceases; after it has ceased for a certain length of time, the same series of phenomena again arises, and observes the same course as before; and this alternation is repeated many times. It has been already stated that the length of time from the end of one paroxysm to the beginning of another is called an intermission, while the length of time from the beginning of one paroxysm to the beginning of the next is termed an interval.

Different names are given to the different varieties of this fever according to the length of the *interval.* If one paroxysm be succeeded by another within the space of twenty-four hours, the ague is termed a quotidian; if after forty-eight hours, a tertian; if after seventy-two hours, a quartan; if after ninety-six hours, a quintan. Those with longer intervals are usually termed erratic. The most common form in this country is a tertian; the next most common, a quartan; the next, a quotidian; the least frequent, a quintan. During the Peninsular war the quotidian was the prevailing type amongst our soldiers. M. Maillot also found that amongst the French troops in the North of Africa, the quotidian was the prevailing type.

Agues are divided into vernal and autumnal; the vernal beginning in February, and the autumnal in August. There is a great difference in their character. The vernal in general are milder and easily cured, while the autumnal are often severe and obstinate.

It sometimes happens that two intermittents attack the same person at the same time, and the ague is then said to be complicated. The most common complication is the case in which two tertians or two quartans attack simultaneously. What is called the double tertian, for example, consists of two tertians, each of which attacks at its regular time, and consequently the paroxysm occurs every day. This form of ague is distinguished from the quotidian, by comparing the paroxysms with each other. Though a paroxysm occur every day, yet if they be carefully observed it will be found that the alternate paroxysms only resemble each other, while if the paroxysm of a preceding day be compared with that of a succeeding day, some manifest difference will be observable. There may also be another form of the double tertian; namely, with two paroxysms on one day, and another on the following day; or there may be a triple tertian, with two paroxysms on each alternate day, and one only in the intervals. The double quartan also varies. It may occur with two paroxysms on the first day, none on the second or third, two again on the fourth day, or with a paroxysm on the first day, another on the second, but none on the third.

But whatever be the form of fever, the nature of it is essentially the same: yet the form is of some consequence, as denoting the severity and tendency of the disease; for a quartan is far more obstinate than a tertian, while a quotidian is apt to change into a continued fever. Quartans, for the most part, appear in autumn, while tertians are the most common in spring.

Whatever be the form of fever, the duration of the paroxysm is different in almost every different case. The longer the paroxysm, the shorter the intermission; the shorter the intermission, the longer the paroxysm. An extension of the period of the intermission, or a postponement of the period of attack, is in general a favourable event, denoting that the disease is declining; on the contrary, a prolongation of the paroxysm, or an anticipation of the period of attack, marks an increase in the severity of the disease, and is a sign that the intermittent is about to lapse into a remittent or into a continued fever.

From the preceding history of the disease it is clear, that the distinguishing character of intermittent fever is the regular return of the paroxysm at a fixed period, the entire cessation of it after a certain time, and the renewal of it after a specific interval, according to the species of the ague. Nevertheless, though these distinct intermissions and accessions are always apparent when the ague is regular, yet in the most severe and formidable cases it entirely loses its intermittent character and assumes a remittent, or even a continued form.

Cases which are frequently considered and treated as continued fevers, are often of the nature of intermittents. If a fever, truly of an intermittent nature, be of a bad kind, it often commences with the form of an alarming and dangerous continued fever; but as the disease declines and becomes milder, the intermission becomes apparent, and the true nature of the malady manifest; while, if an intermittent commences under its own form, but in its progress becomes severe, it often changes into a disease which cannot be distinguished from a continued fever.

There is nothing in the nature of disease more curious and inexplicable than this property of periodicity. During the intermission what becomes of the malady? Why after a specific interval does it uniformly recur? Physicians have endeavoured to refer this singular phenomenon, which, if it were not so clearly seen would not be credible, to the principle of habit; but this really affords no explanation, and in fact we have not advanced a single step towards the elucidation of these questions beyond the point at which Sydenham left them 200 years ago.

Exciting Cause of Ague.—That the effluvia which arise from stagnant water or marshy ground, are the immediate or the exciting cause of this disease, is now universally admitted. What the nature of these effluvia is, is not known. Neither their physical nor their chemical properties have been ascertained. Even their presence is known only by their effects on the human constitution. No other test of their existence has as yet been ascertained. The most distinguished chemists have applied all the resources of their art to the investigation of this subject, but hitherto with so little success, that all which they have ascertained is the mere fact, that in certain situations an aëriform substance is generated capable of producing intermittent, remittent, and continued fever, together with several other painful and dangerous diseases.

Though this poison be generated in the greatest abundance and intensity in marshy and swampy ground, yet without doubt it is also produced in situations which have none of the characters of a marsh. Wherever the ground is moist and contains decaying vegetable matter, this poison is capable of being generated. Woods afford it in almost as large a quantity as marshes, because in woods the ground remains a long time damp, and always abounds with decaying vegetable matter. Hence in all the densely wooded parts of England both intermittent and remittent fevers are rife. This is especially the case in the woody districts of Kent, Sussex, Hampshire, Wales, &c. The jungle of India consists of a low and dense brushwood, or a thicket of reeds and grass; and intense heat acting on the wet and decaying vegetation with which it abounds, the poison is here produced in the highest degree of concentration. Rice grounds, for the same reason, are notoriously productive of it. But it is curious that the clearing of woods sometimes increases the evil. Dr. Rush states that, in Pennsylvania, epidemics invariably follow the clearing and cultivation of forest lands, and that they do not disappear until after many years of continued cultivation. The same remark has been made in France; and the district of Bresse (Lyonnais), which was comparatively healthy when full of woods, has become nearly depopulated since they were cut down. The shade of the trees keeps the sun to a great extent from the wet ground; but the removal of the trees exposes the wet ground to the full action of the sun. Meadow land, imperfectly drained, contains in abundance the two conditions, moisture and decaying vegetable matter, and is in England a frequent and extended source of this poison. It is commonly considered that a large space of land in the condition of a marsh, a swamp, a thick and damp wood, or an undrained meadow, is necessary to the production of the poison; but while it is not easy to fix the minimum of the space that is requisite, it is quite certain that an exceedingly small space is sufficient. These facts show, in a striking manner, the danger and folly of creating artificial marshes as ornaments in parks and gardens.

Wherever generated, this poison, either mechanically mixed or chemically combined in the air, is capable of being conveyed in unimpaired power to a considerable distance by currents of wind. The influence of the Pontine marshes, situated at the distance of fourteen miles from Rome, is often felt in that city.

In warm climates where this poison is generated in the highest degree of intensity, it sometimes proves suddenly fatal to individuals of a ship's crew when the vessel is several miles from land. It is brought with the land-wind. It seems certain that the poison can be carried as far as the smell of the land is perceptible. A memorable instance of this occurred in a vessel that was five miles from shore. The wind suddenly shifted; the smell of land was perceptible; the nature of the neighbouring coast was known to the people on board, and the danger duly appreciated; every one that could do so hastened below to save himself from the noxious breeze. Some of the crew however were unavoidably employed on deck; the armourer of the ship was detained a few minutes in order to clear an obstruction in the chain cable, and was seized with fatal cholera in the very act in which he was engaged. Of the men that remained on deck, several died of the same disease in a few hours,—the attack having been simultaneous with the very first perception of the land smell; and in our country it is often conveyed by currents of wind to a distance of several miles. It frequently proceeds to the hills of Kent, for example, several miles distant from the marshes of Erith, Northfleet, or Gravesend. The watery vapour that is so apt to arise in situations most favourable to the generation of this poison, appears to be an exceedingly formidable conductor of it. Sir John Pringle, who had many opportunities of observing this fact in the campaigns in Flanders, about the middle of the last century, uniformly found that the number of men who were seized with sickness during the prevalence of a fog, far exceeded the number attacked when the weather was clear, though he did not attribute to the fog the production of the poison, but justly considered it as merely the conductor of it.

There are spots in which this poison is generated in such quantity and intensity, as to be capable of killing instantaneously whoever is exposed to it. Exposure to it in certain situations has proved fatal with a rapidity and certainty equalled only by a mortal dose of Prussic acid. Exposure to it in other situations produces what appears to be, and what is sometimes mistaken for, apoplexy—an affection of the brain, causing death more rapidly than almost any other disease to which the human body is subject. Exposure to it when less concentrated produces malignant fever of a continued form, destroying life in a few days or hours. Exposure to a still smaller concentration produces remittent, and to a yet smaller, the milder form of intermittent fever. And it may be so minute in quantity or so destitute of virulence in its own nature, as to be incapable of producing even intermittent fever, in its regular and well-marked form, and yet sufficiently potent to produce a long catalogue of grievous maladies. The secondary diseases which have this origin, and which have been much overlooked, consist for the most part of those painful affections of the nerves, which have been lately classed together under the general term of *neuralgia*. [NEURALGIA.] The exquisitely painful, and too often unmanageable diseases called tic douloureux, the disease called sciatica, the toothache, and more especially periodical headache, are oftentimes clearly traceable to this poison, and are as certainly produced by it as the most distinct and regular ague. Persons who live in situations where this poison is generated in abundance may never have ague, but at the same time they never enjoy a moment's health; while it is certain that long-continued exposure to it, though it may not produce any specific disease, included in the catalogue of the nosologist, fearfully abridges the term of life. Few persons in such situations attain the age of fifty. In some parts of America few of the inhabitants formerly lived beyond the age of forty; those who survived thus long had, at that early period, all the characters of extreme old age. Already, in those very situations, by the clearing, draining, and general cultivation of the land, the average term of life has been extended fifteen or even twenty years. There can be no question that the value of life which in modern times has increased so much in our own country, and which has improved in the rural districts in proportion to the better cultivation and the more complete draining of the land; and in the larger towns and cities to the better ventilation and the greater cleanliness for which they have been remarkable, has been mainly owing to these causes. So recently as the beginning of the present century, a celebrated physician, who had large experience of this matter, states, as a fact that came within his own observation and experience, that in small villages, in which the annual number of persons attacked with ague amounted to 200, not one case had occurred for several years.

Remote or predisposing Cause. The remote, or the predisposing cause of the disease is that which brings the system into a condition capable of being affected by the immediate or exciting cause. Whatever diminishes the vigorous action of the organs, impairs their functions and so weakens the general strength of the system, is capable of becoming a predisposing cause of fever; and every predisposing cause acts in one or other of these modes, and becomes a predisposing cause only and in proportion as it lessens the energy of the system, or disturbs the balance of its actions, which in fact is to render some portion of it weak. During a state of vigorous health the body is endowed with the power of resisting the influence of noxious agents, which in a less perfect state of health are capable of producing intense and fatal disease; and the action of all predisposing causes is to lessen this resisting power, or to weaken the energies of life.

Of all the predisposing causes of ague the most powerful is the continued presence, and the slow operation of the immediate or the exciting cause. The manner in which the immediate or the exciting cause of fever operates as a predisposing cause has been amply illustrated by Dr. Southwood Smith. "It is a matter of constant observation," says this author, "that the febrile poison may be present in sufficient intensity to affect the health, without being sufficiently potent to produce fever. In this case the energy of the action of the organs is diminished, their functions are languidly performed, the entire system is weakened, and this increases until at length the power of resistance is less than the power of the poison. Whenever this happens, fever is induced; not that the power of the poison may be at all increased, but the condition of the system is changed, in consequence of which it is capable of offering less resistance to the noxious agent that assails it."

Dr. Potter gives a remarkable example of this fact, with regard to the yellow fever, which fell under his own observation, and states other facts strikingly illustrative of the influence and operation of the predisposing causes. Strangers, from certain countries, he informs us, are insusceptible of yellow fever in America. In the most malignant and protracted epidemics which afflict that country, these strangers uniformly escape; emigrants from the West Indies, and other warm latitudes, for example, invariably resist the cause which produces these maladies in the native inhabitants. But the curious fact is, that such persons are unable permanently to resist the operation of the exciting cause; for, after a residence in America of some years, their constitution is so completely assimilated by the influence of the climate to that of the American, that they become equally sensible to its febrile miasma, and are as exquisitely impressed by them as the American citizens themselves. The illustration is equally striking and instructive if the position be reversed. The natives of northern climates are extremely susceptible to the influence of these miasma; that susceptibility is in exact proportion to the latitude of their country: those from the north of Europe scarcely ever escape an attack; the natives of Great Britain are nearly as susceptible to the influence of the poison, while persons even from the more northern countries of the United States are more liable to the disease than the citizens of the southern and middle States."

Among the other predisposing causes may be reckoned the period of life. All persons between the age of puberty and that of thirty-eight are peculiarly predisposed to this disease. After the disease has once existed, there remains in the constitution a remarkable susceptibility to its recurrence; and that from very slight causes, as from the prevalence of an easterly wind, or exposure to a very minute quantity of the poison that originally produced it, such as would not affect a person who had never been the subject of the disease. Hence, persons who have been once or twice, or oftener affected with ague, are most delicate tests of the presence of the exciting poison. Deficient and poor diet; intemperance; physical and mental fatigue; anxiety, cold, damp, debility, however induced—all these are extremely powerful predisposing causes. They enable a less dose of the poison to produce the fever, and they increase the intensity of it when established. They all act by weakening the resisting power inherent in the constitution, that is, by enfeebling the powers of life.

Treatment of Ague.—The first object in the treatment of a person affected with ague is to remove him from the influence of the poison by taking him out of an unhealthy, and placing him in a healthy situation. Unless this can be done, every remedy employed must act at a great disadvantage, and the power of the poison, or the debility of the patient, may be such as to render every effort to cure the disease unavailing without a change of residence. Often, however, circumstances will not admit of the removal of the patient. Whenever this is the case, the sick person must at least be put and kept in an apartment the most remote from the noxious spot, and it is a good and important general rule to place him in the highest part of the house. When this precaution is neglected, remedies constantly fail which readily and completely succeed when it is observed.

The treatment of ague includes the management during the paroxysm, the intermission, and the convalescence.

First, of the treatment during the paroxysm. The approach of the paroxysm should be carefully watched. The moment the first indication of its accession is apparent, an emetic, consisting of twenty grains of the powder of ipecacuanha with one grain of the tartar emetic, should be given, and as soon as the operation of the emetic is over, a draught should be taken, consisting of from twenty to forty drops of laudanum in an ounce and a half of camphor julep. This plan, in almost all cases, will completely stop the coming on of the cold fit; in a great number of cases it will also prevent altogether the accession of the hot fit, inducing at once the sweating stage, that is, the stage which constitutes the solution of the paroxysm. But if it should not actually stop the accession of the hot stage, it will assuredly diminish its violence and shorten its duration; and as soon as the hot stage is formed, the laudanum should be repeated in smaller doses, namely, in doses of from ten to twelve drops, repeated every hour, and continued until the sweating stage is completely established.

As soon as the cessation of the sweating stage terminates the paroxysm, and the latter is succeeded by the stage of intermission, cinchona bark should be freely taken. Of all the preparations of bark, the sulphate of quinine is incomparably the best. The dose is from two to four grains, and the most convenient mode of administering it is in the form of pill. During the whole period of the intermission, the dose of quinine should be repeated every hour, or every two hours, according to the urgency of the case. If the biliary secretion be unhealthy, which it almost always is, it will be useful to combine with every alternate dose of the quinine, from the sixth to the half of a grain of blue pill, together with two grains of the extract of gentian. If the bowels be constipated, the addition to each pill of from one to two grains of the extract of rhubarb will form an excellent aperient. Given in this mode, the extract of rhubarb moderately, but in general effectually, stimulates the alimentary canal, gently increasing its action, without producing purging. If, however, the bowels be constitutionally torpid, or be rendered so by the disease, a more active aperient must be substituted, and such will be found in the compound decoction of aloes, or the infusion of senna with camomile. The condition of the bowels must never be neglected, for a state of constipation will powerfully counteract every remedy.

This plan should be continued without intermission until the recurrence of the symptoms which denote a fresh accession of the paroxysm. Then the quinine, &c. should be suspended, and the emetic should be again repeated, which, as soon as its action has ceased, should be followed by the opiate, and this, on the solution of the paroxysm, by the bark, and so on in a constant series, until the paroxysm return no more. By this method of treatment the disease is usually cured after the third accession, consequently it is seldom necessary to repeat the emetic more than three times, and often twice and even once is sufficient.

Quinine, however powerful and effectual during the intermission, is commonly conceived to be useless and even pernicious during the paroxysm. But this is the period when opium is most effectual. It has even been given with success as the sole remedy. Dr. Trotter, who had an opportunity of observing its effects on a large scale in the Channel fleet, under Earl Howe, states, that whenever the sick felt the first approach of an attack, he prescribed from thirty to forty drops of laudanum; that if this dose did not bring on some warmth in the course of ten or fifteen minutes, he gave from twelve to fifteen drops more; that it was seldom necessary to increase the quantity beyond sixty drops in the space of an hour, decided relief being always afforded in that time; that in a few minutes from the exhibition of the opiate the spirits became exhilarated; the constriction on the skin was removed, and was followed by relaxation; the countenance looked more animated; a flush spread itself over the cheek; the pulse, from having been weak, quick, irregular, and sometimes intermittent, became less frequent, and more full and more equal; an agreeable warmth was diffused over the whole frame, and every unpleasant feeling vanished sometimes in a quarter of an hour. As soon as any symptoms indicated a return of the paroxysm, the laudanum was repeated in the same manner as at the accession of a former fit, and always with equal success, so that the patient seldom experienced much trembling and shaking; it was observed that the second paroxysm was commonly an hour or two later in the day than the preceding, and but few instances occurred of a return of the disease after the third paroxysm. The patients themselves were so satisfied of the efficacy of this remedy, that the moment they felt the first approach of an attack, they were sure to run to the cock-pit for relief. Dr. Lind, who also tried this remedy on a large scale, states that according to his experience, the good effects of opium are more uniform and powerful in intermittent fever than in any other disease, and that it affects the disease more rapidly than any other medicine; that if taken during the intermissions it has no effect either in preventing or mitigating the succeeding paroxysm; that when given in the cold fit, it occasionally removed it; but that when administered half an hour after the commencement of a hot fit, it almost always afforded immediate relief.

It is not sufficient that the recurrence of the paroxysm has been stopped once or twice by the use of the remedies prescribed. It should be borne in mind that there is in this disease a great tendency to relapse, and this tendency continues through the whole period of convalescence, and for some time after. The quinine should be continued in smaller doses for some weeks after the last paroxysm has supervened, especially if the weather be damp or easterly winds prevail.

If aperients are necessary, they should be warm and aromatic, and given during the intermission, so that their operation may be over before the accession of the paroxysm. Organic disease is occasionally produced by ague. The organs that are most liable to be diseased are the liver and the spleen; these become enlarged and hardened, scirrhous, as it is technically termed. The tumours occasionally press upon the great veins of the liver, and prevent the blood from passing freely from the abdominal viscera, and produce dropsy; they also press upon the ducts that carry the blood from the liver into the duodenum, or the small intestines which receive it; it may, therefore, be taken up by the absorbents and carried into the blood, diffused over the system, and so produce jaundice. In the same way diarrhœa may be produced.

Change of situation is a most powerful remedy; 1st, because it may remove the patient out of the sphere of the poison that produces the malady; 2ndly, because this is one of the diseases in which mere change of air is beneficial.

This disease is peculiarly apt to return. Relapse is brought on by very slight causes; a very small dose of the poison will renew it.

It is probable that errors in diet, or constipation will also do it. It is certain that cold, and that the east wind will do so; but it is probable that in the cold and moist air, and in the east wind, there is diffused some of the malaria. The patient should not go out in damp or cold weather, or during the east wind.

In protracted and obstinate cases which do not yield readily to quinine, arsenic is a very powerful remedy, and its efficiency is increased by its combination with opium or quinine. The proper dose of the arsenic is from two or three to ten drops of the liquor arsenicalis three times a day. This remedy should always be given soon after a meal; for if taken when the stomach is empty, it is apt to produce pain and vomiting. The operation of the remedy should also be carefully watched day by day; for, like other mineral poisons, it is apt to lie latent in the system for a considerable time, producing no apparent effect, and then suddenly to produce violent symptoms.

AIDE-DE-CAMP, a French term, denoting a military officer usually of the rank of captain, one or more of whom is attached to every general officer, and conveys all his orders to the different parts of his command. A field-marshal is entitled to four, a lieutenant-general to two, and a major-general to one. The monarch appoints as many aides-de-camp as he pleases, and this situation confers the rank of colonel. At the end of 1858, the number of aides-de-camp to the queen was thirty-five. There were also eleven naval aides-de-camp to the queen, one of whom, of the rank of admiral, is styled first and principal aide-de-camp, and has a salary of 365*l.* per annum; and ten others, of the rank of captain, have 182*l.* 11*s.* per annum. There are also two aides-de-camp appointed by the queen from the officers of the Royal Marines, whose salary is the same as that of the naval aides-de-camp.

AIDS (from the French *Aides*, which in the sense of a tax is used only in the plural number). Under the feudal system, aids were claims of the lord upon the vassal, not so directly connected with the tenure of land as reliefs, fines, and escheats. The nature of these claims is indicated by the term: they were rather extraordinary contributions than demands due according to the strict feudal system, though they were founded on the relation of lord and vassal. These aids varied according to local custom, and became in course of time oppressive exactions. The aids which are mentioned in the 'Grand Costumier' of Normandy for knighting the lord's eldest son, for marrying his eldest daughter, and for ransoming the lord from captivity, were in use in England, having been probably introduced by the Normans. But other aids were also established by usage or the exactions of the lords, for by Magna Charta, c. 12, it is provided that the king shall take no aids, except the three above mentioned, without the consent of Parliament, and that the inferior lords shall not take any other aids.

The amount of the two aids for knighting the lord's eldest son and marrying his eldest daughter was limited to a certain sum by the Statute of Westminster 1, 3 Ed. I. c. 36. The aid which was to ransom the lord when taken prisoner was of course uncertain in amount. Aids for knighting the lord's son and marrying the lord's daughter are abolished by the stat. 12 Car. II. c. 24. The aid for ransoming the lord is obsolete.

Aids is also a general name for the extraordinary grants which are made by the House of Commons to the crown for various purposes. In this sense, aids, subsidies, and the modern term supplies, are the same thing. The aids were in fact the origin of the modern system of taxation. (Blackst. 'Com.,' vol. i. p. 302; vol. ii. pp. 62, 85.)

Auxilia is the Latin word used by Bracton and other writers when they are speaking of the feudal aids above enumerated. The word *Aide* is derived from the Low Latin *Adiuda*. (Du Cange, 'Gloss. Med. et Infim. Latin.') The Spanish form *ayuda* ('assistance'), and the Italian *aiuto*, also clearly indicate the origin of the word 'aide,' which is from the participial form *adjuta* of the Latin verb *adjurare*.

AIR. This word is derived from the Greek ἀήρ and Latin *aer*. Though generally applied only to the material of the atmosphere, this term was, about the middle of the last century, extended to all the gases, as they were successively discovered, with a distinctive name for each. Though we confine ourselves here to the properties of atmospheric air only, we give the references to the modern names of the principal *airs*, as they were then called, which will be found mentioned in the chemical works of the last century.

Dephlogisticated Air, Empyreal Air, Vital Air,	see	Oxygen.
Phlogisticated Air	see	Nitrogen.
Nitrous Air,	see	Nitric Oxide, Deutoxide of Nitrogen.
Dephlogisticated Nitrous Air,	see	Nitrous Oxide. Protoxide of Nitrogen.
Inflammable Air,	see	Hydrogen.
Fixed Air,	see	Carbonic Acid.
Alkaline Air,	see	Ammonia.

The air which envelopes the globe is a *mechanical mixture* of two of those simple substances, to which chemists have given the name of *elementary;* viz., oxygen and nitrogen, with a very small proportion of carbonic acid, and water in the state of vapour. The two last are considered as accidental ingredients, and not constituent parts; as well on account of the smallness of their quantity, as because they occur in different proportions at different times. The atmosphere also contains a variable but minute trace of ammonia; traces of nitric acid, and of some compound of carbon and hydrogen, and often in towns sulphurous acid or sulphuretted hydrogen.

Referring only to the two principal ingredients, air consists on an average of 20·81 of oxygen by *measure*, and 71·19 of nitrogen in 100 parts; or, by *weight*, of 23·01 of oxygen and 76·99 of nitrogen. Whether the air be brought from an elevation of four miles above the surface of the earth, or collected on the summit of the Alps, or from crowded towns, or open plains, in various parts of the globe, it presents no sensible difference, with respect to its principal constituents, from the proportions above given. With respect to the weight of air, 100 cubic inches of dry air at mean temperature and pressure weigh rather more than 31 grains, the most accurate result being probably that of Biot and Arago, viz., 31·074 grains. Hence the weight of a given volume of air at 60° F. and 30 in. Bar. is only $\frac{1}{813}$th that of an equal bulk of water at the same temperature. Water dissolves about $\frac{1}{20}$th of its bulk of oxygen, and $\frac{1}{40}$th of nitrogen; hence rain water and melted snow contain in solution a larger proportion of oxygen than exists in the atmosphere, or about one part of oxygen to two of nitrogen, a circumstance of great importance to aquatic animals. The carbonic acid of the air is produced at the expense of its oxygen during the processes of respiration, combustion, fermentation, &c. Air that has been respired contains about 3½ per cent. of carbonic acid, although the proportion in the atmosphere does not exceed ·04 per cent. Certain mineral springs and the action of subterranean heat in volcanic districts upon limestone rocks beneath the surface, are also sources of carbonic acid to the air.

The average composition of the atmosphere in England, in 100 parts by volume, is as follows:

	Oxygen	20·61
	Nitrogen	77·95
	Carbonic Acid	·04
	Aqueous Vapour	1·40
	Nitric Acid, Ammonia, Carburetted Hydrogen	traces.
And in towns	Sulphuretted Hydrogen, Sulphurous Acid	traces.

Although the constituents of the atmosphere are of very different densities, yet, in consequence of the principle of DIFFUSION, they are uniformly mixed: one atom of oxygen is accompanied by four atoms of nitrogen, but yet so slightly held together, that the oxygen is readily separated from the nitrogen when required for the purposes of animal and vegetable life or combustion, and by the operation of the same principle, the heavy carbonic acid is distributed through the air, so that plants may easily absorb it, decompose it, retain the carbon as material for growth, and return the pure oxygen to the atmosphere. Some chemists, notwithstanding, have considered the air to be a chemical compound of 2 atoms of nitrogen to 1 of oxygen. An atomic compound of this proportion gives a ratio of 20 : 80 in volume, which is very nearly that given above, as deduced from experiment. M. Regnault, however ('Chimie,' i. 144), has shown that this view is hardly tenable, however remarkable the coincidence may be.

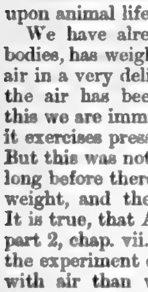
The air is a *mixture* of oxygen and nitrogen, and not a *chemical combination*. In what the difference consists, it is impossible at present to say; but the distinction may be illustrated by the following experiment, which we introduce the more readily, as we shall afterwards have occasion to refer to it. If eight grains of oxygen gas and one grain of hydrogen be confined in a glass tube from which the air has been previously excluded, they may be mixed in that state, and the *mixture* thus formed will not prevent either gas from separating from the other, and combining with any third body. That is, the oxygen, for example, will combine as readily with any substance which has a great affinity for it, as if the hydrogen were not present. But if an electric spark be passed through the tube, a new substance is formed out of the oxygen and hydrogen, by some species of mutual connexion very different from the former one, and which has the name of *chemical combination*. Nine grains of common water are formed from the eight of oxygen and one of hydrogen. The oxygen will not now easily be separated from the hydrogen by the application of a third substance, and there are few for which the oxygen has a greater *affinity* than for the hydrogen. The general characters which distinguish chemical combination from simple mixture, are, that in the former there is usually an alteration in the SPECIFIC GRAVITY, REFRACTIVE POWER, law of DILATATION from heat, &c.; while there is, generally, at the same time such a change of properties as no *à priori* reasoning could predict.

We have seen in the experiments already cited, that two elements which, when properly combined, produce a substance very different from either, may be placed in juxtaposition (such as is produced by mere mixture) without any such consequence following. If nitrogen and oxygen formed no other compound except atmospheric air, we might, perhaps, call the latter a chemical compound; but we should then be obliged to say, that the affinity of nitrogen for oxygen was singularly small. But the contrary of this is the fact. One equivalent of nitrogen may unite with one, two, three, four, or five equivalents of oxygen, forming the *nitrous* and *nitric oxides*, and the *nitrous*, *hyponitric*, and *nitric acids*; all of which have every character of chemical combinations.

The composition of air may be ascertained either *synthetically* or *analytically*. Synthetically, by mixing the proportions already noticed of oxygen and nitrogen; in which case it is found, that the mixture differs in no respect from common air: analytically, by an experiment similar to the one already cited; in which, however, it is presumed that we know the composition of water. If hydrogen be added to or mixed with a portion of common air, and an electric spark be passed through the mixture, it will be found that the hydrogen has combined with eight times its weight of oxygen (if there be so much), and has produced nine times its weight of water. In this way, by trial, the quantity of hydrogen may be found which will combine with all the oxygen in the mixture, and the remainder is then found to be simply nitrogen. A more accurate method, however, is to allow air to stream slowly over a weighed quantity of heated copper, whereby the oxygen is absorbed, and the nitrogen is received into an exhausted flask, weighed before the experiment was begun and after it was finished; the quantity of oxygen is found by the gain in weight experienced by the tube containing the copper.

Such are the principal chemical properties of air. For its effects upon animal life, see RESPIRATION.

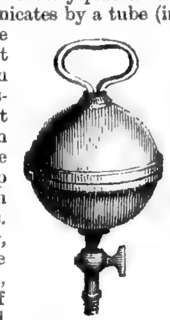
We have already observed that the air, in common with all other bodies, has weight. This is proved by weighing a bottle which contains air in a very delicate balance, and then by repeating the process after the air has been exhausted from the bottle by the air-pump. From this we are immediately led to conclude that, like all other heavy fluids, it exercises pressure upon all substances which are in contact with it. But this was not the order of discovery. The pressure was ascertained long before there was any other reason except analogy for inferring the weight, and the latter discovery was a consequence of the former. It is true, that Aristotle (Stanley's 'History of Philosophy, Aristotle,' part 2, chap. vii.) expressly mentions that air has weight, and even cites the experiment of a bladder, which he asserts weighs more when filled with air than when empty: but his followers of the middle ages entirely abandoned the doctrine. We shall speak more at length of the discovery, under the heads BAROMETER and ATMOSPHERE. It is here sufficient to observe, that the density of the air depends upon, and is a consequence of, the pressure of the superincumbent atmosphere. For the air is an elastic fluid, that is, its bulk increases, and its density diminishes, whenever the exterior pressure is wholly or partially removed. Let a loose bladder, tied at the mouth, and not so full of air as to be distended, be placed under the receiver of an air-pump, so that the air which presses the outside of the bladder can be exhausted. The interior air will expand so soon as the exhaustion begins, will presently distend the bladder to its fullest dimensions, and will even burst it. On the re-admission of the air into the space surrounding the bladder, the latter will gradually resume its former dimensions, and its withered or flaccid appearance.



As we ascend the atmosphere, the superincumbent column of air becomes of less weight, and the density becomes less; that is, a cubic foot at the height of 1000 feet above the ground is not so heavy, or does not contain so much air, as a cubic foot at the surface of the earth: which is thus explained. The air having in itself a force which tends to separate the particles from one another, or to expand the whole bulk, but which force grows less and less as the particles are more and more separated, that is, as the bulk increases, the state of rest will always be that in which the elastic force upon a square inch of the surface of air, arising from its own constitution, just balances the external pressure upon that square inch. To illustrate this, suppose a vertical tube, A B C D, open at both ends, *at first*, and filled with air, which communicates with the exterior atmosphere. Place a slight membrane, E F, across it, which can be moved up and down the tube, so that, except for friction, it would be displaced if the pressures of the air above and below it were in the least degree unequal. At present there are two equal and contrary pressures on the two sides of E F, arising from the weight of the column of air above E F. For if the pressure from underneath were less than that from above, E F would move downwards, and *vice versâ*. Now cover the end B D of the tube, so that the air in E F D B shall have no communication with the exterior air. The membrane E F still remains at rest; that is, the air E F D B, without being pressed by the exterior atmosphere through the section B D, exerts the same force upon E F from below as the exterior atmosphere does from above. This is what we mean by the *elastic force* of the atmosphere, as distinguished from the weight of the superincumbent column of air. The two being always equal, may easily be confounded; we only wish to impress upon the reader, that this repulsive force of the particles of air, of which we know nothing but its effects, is a counterbalancing force from within, so to speak, to the pressure from without, and is greater or less according to the less or greater nearness of the particles, as we shall proceed to exemplify.

To get a more distinct idea of the superincumbent pressure on E F, suppose the air to be entirely removed from above E F, so that the membrane must be held down in order to prevent the uncounterbalanced force beneath from driving it up, and exhibiting the phenomena of the air-gun. Let a liquid, mercury for example, be poured into the tube, until there is no longer any occasion to hold down E F, or until the weight of the mercury will just counterbalance the pressure of the air from below. In the average state of the atmosphere, this will require about 30 inches of the tube above E F to be filled with mercury. Now, let half the mercury be removed; that is, let it only stand 15 inches above E F. This is not sufficient to counterbalance the pressure from beneath, and the membrane will rise to twice its height above B D; that is, the air will now occupy twice the space which it did before. But this will not happen immediately, for it will settle at first at something less than the height we have mentioned, and attain that height by degrees. The reason would be manifest if a thermometer were placed in the space E F B D; for it would be found that the thermometer would *fall* when the expansion began, and would gradually regain its original height as the membrane acquired its full distance from B D. Similarly, if the quantity of mercury were doubled and made to stand at 60 inches above E F, the pressure on E F would be greater than that from beneath; the membrane would descend, the thermometer *rising* at the same time; and by the time the thermometer again indicated the same temperature as at first, the membrane E F would stand at half its original distance from B D. If any other quantities of mercury were added or taken away similar results would be found, so soon as the alteration of temperature was balanced by the surrounding atmosphere, which, in the first case, imparts heat to the apparatus, and, in the second, receives heat from it. Thus, if only one-third of the mercury were left, the air would overbalance it until it had expanded into three times its dimensions. If the mercury were increased five-fold, the air would never furnish a counterpoise until it was reduced to one-fifth of its former dimensions. This remarkable law, which holds for all gases as well as air, may be expressed as follows: *at the same temperature*, the elastic forces of two portions of air (or, which is the same thing, the weights of mercury they will balance) are in direct proportion to the densities, or in inverse proportion to the spaces occupied by these portions. In the apparatus above described, we do not pretend to show a good practical method of actually performing the experiment. For this purpose we must refer to AIR-PUMP.

The very great pressure of the atmosphere is illustrated by the following experiment. Two hollow hemispheres are loosely placed one upon the other as in the figure: the lower communicates by a tube (in which is a stop-cock, open for the present) with the exhausting apparatus of an air-pump. At present there is no impediment to lifting the upper from the lower hemisphere except its weight; the pressure of the air from within counterbalancing that from without. But if the air be withdrawn from the interior, and the stop-cock closed so that the apparatus can be unscrewed from the air-pump without allowing the air to enter, it will require an enormous force to separate the two hemispheres. Thus, if *all* the air be removed from the interior, there will be a pressure of 15 lbs. on each square inch of the section of the hemispheres; hence, supposing the diameter to be 4 inches, the area of the section will be about $12\frac{1}{2}$ square inches, and the force required to separate them will be $12\frac{1}{2} \times 15 = 187\frac{1}{2}$ lbs. This experiment was first performed by Otto Guericke, at Magdeburg, in 1654. Such being the external pressure, it may appear extraordinary that the human body is capable of supporting it without being crushed to atoms. The pressure on the body is computed at several tons. But the cause of wonder is purely imaginary. In the words of Dr. Robison "the human body is a bundle of solids, filled or mixed with fluids, and there are few or no parts of it which are empty. All communicate either by vessels or pores, and the whole surface is a *sieve*, through which the insensible perspiration is performed. The whole extended surface of the lungs is open to the pressure of the atmosphere; everything is therefore in equilibrio; and if free or speedy access be given to every part, the body will not be damaged by the pressure, however



great, any more than a wet sponge would be deranged by pressing it any depth in water." ('Mechanical Philosophy,' vol. iii. p. 541.)

The temperature of air, as already noticed, influences its elastic force. We have every reason to conclude, that the principal properties of this and all other gases are a consequence of the presence of heat, though we do not know what the latter is. It is probable that air would become first liquid, and then solid, if it could be made sufficiently cold. Like all other substances, air gives out heat when it is compressed, that is, raises the temperature of surrounding bodies, and *vice versâ*. This is strikingly illustrated by the fact that tinder can be set on fire when the air contained in a brass cylinder is suddenly and violently compressed by a piston.

From careful experiments it appears, that air and all other gases, as well as vapours, and also all mixtures of gases and vapours, obtain an increase of elastic force for every increase of temperature, and expand therefore, if expansion be possible, in the vessel which contains them. The quantity of this expansion, when the temperature passes from the freezing to the boiling point of water (that is, from 32° to 212° of Fahrenheit's, from 0° to 80° of Réaumur's, and from 0° to 100° of the Centigrade, thermometers), is 366 parts out of a thousand of the bulk which it had at the freezing point. That is, in the apparatus indicated in the preceding part of this article, form a graduated scale along B A, and suppose that B E contains a thousand parts, and that, the upper air being removed, as much mercury is poured in above E F as will cause the membrane E F to stand at E, when the temperature of the air is at the freezing point of water. Then, if the air be gradually heated from the freezing to the boiling point of water, either more mercury must be poured in, or the membrane with the superincumbent mercury will rise through 366 divisions more of the scale, and E will stand at 1366. And this dilatation is uniform: that is, whatever expansion arises from an increase of 12° of temperature, half as much arises from an increase of 6°, twice as much from one of 24°, and so on. This remarkable law, which holds, with perhaps a slight variation, at very high and very low temperatures, was discovered nearly at the same time by Dalton in England and Gay-Lussac in France. Now, in Fahrenheit's thermometer there are 212°—32°, or 180° between the boiling and freezing points of water; 80° in Réaumur's; and 100° in the Centigrade. Consequently, the whole increase of bulk, or $\frac{366}{1000}$, will give $\frac{366}{180000}$, $\frac{366}{80000}$, and $\frac{366}{100000}$, for the variations of bulk corresponding to a rise of one degree of temperature on each of the three thermometers; that is, about $\frac{1}{491}$, $\frac{1}{218}$, and $\frac{1}{273}$, respectively. But in applying these rules, it must be recollected that, in taking Fahrenheit's thermometer, for example, the expansion is $\frac{1}{491}$ of the *bulk which it had at the freezing point*. Suppose, for instance, we have a bulk of air which occupies 1000 cubic inches at the temperature of 62° Fahrenheit, and we wish to know how much it would occupy under the same pressure at 82° of the same. The first temperature is 30° above the freezing point. Now, suppose a certain volume of air to consist of 491 parts at the freezing point; then it is clear that, as air expands $\frac{1}{491}$ of its bulk for each degree, this volume at 62° will have become $491 + 30 = 521$ parts. Similarly, at 82° it will be $491 + 50 = 541$ parts. Hence, as 521 (the volume at 62°) : 1000 (also at 62°), so is 541 (the volume at 82°) : 1038⅜, which is the bulk required at 82°.

On the properties of air with regard to other bodies, we may notice that probably there is a slight adhesion of air to many, if not to all, surfaces. A small needle may be made to swim on water, and in this state the water evidently retires from around it, leaving it, as it were, suspended over a hollow in the fluid. This is attributed to the adhesion of a coat of air, which, with the iron, makes the whole specifically lighter than the water. Recent experiments on the pendulum, the most delicate of all philosophical instruments, have led some to suspect, that in addition to the resistance of the air, a slight coating of this substance travels with the pendulum, and thereby causes an irregular addition to its weight. [PENDULUM.]

The air is a permanent gas, incapable of being reduced to the liquid state by cold or pressure. It is also, like most gases, perfectly colourless, especially when we look through small quantities of it; although, if we notice the effect produced by large masses of it, we may consider it to be a coloured gas. Thus, the *blue* colour of the sky is probably merely the colour of the air seen through a length of about 45 miles. Hence, it has been observed by those who have ascended about 5 miles from the earth's surface, when they have left much more than half the atmosphere behind them, that the sky appears of a dark inky hue, owing to the very small reflection and dispersion of the light, while the blue colour no longer appears *above*, but *below* them. Similarly, the *blue* colour of distant hills is owing to the same cause.

In this article we have considered only the chemical and mechanical properties of air. The constitution of the whole mass will come under the article ATMOSPHERE. To complete the subject, refer to OXYGEN, RESPIRATION, COMBUSTION, VENTILATION, ACOUSTICS, AERODYNAMICS, and also to the 'Elements of Chemistry,' by Professor Miller, of King's College, London, and to the 'Cours de Chimie,' by Regnault.

AIR, in music, signifies 'Melody;' the terms are synonymous, it being understood that by both words is meant a succession of single sounds in measured time. The word Air was used in this sense nearly three centuries ago; but it is not now known why such an application of a familiar word was first adopted.

Rousseau says that the name of air is given to all melodies, to distinguish them from recitative. M. Suard, in the 'Encyclopédie Méthodique,' offers the following definition:—a piece of music, composed of a certain number of melodious phrases, united in a regular symmetrical form, and terminating in the key in which it began. Sulzer has followed M. Suard; so has Pietro Lichtenthal; but, without objecting to his definition, we consider the common and simple one the best,—namely, that succession of single sounds, regulated by the laws of musical rhythm, which constitutes what, in homely language, is called a tune. [RHYTHM.]

Air, or melody, is, allowedly, the most important of the constituents of music. A composition may be replete with learned and ingenious harmony, may abound in fugue, in imitation, and all the contrivances of science, but without good melody will never appeal to the heart, and seldom afford any gratification to the ear. Haydn carried this opinion so far as to say, "Let your air be good, and your composition, whatever it may be, will possess beauty, and must certainly please." Air is in music what design and outline are in the sister art of painting: harmony is the filling up, and the colouring.

The Greeks had many kinds of airs, which they called *nomes*, or songs; and we learn from the work of Philodemus on Music, recovered from the ruins of Herculaneum, that every trade and occupation had its Νομοι, or appropriate airs, which were played or sung to the workmen while they laboured.

The various kinds of airs, instrumental as well as vocal, will be found under their different heads. [ALLEMANDE; BARCAROLLE; &c.] In music composed for the theatre, and which is constantly introduced into the concert-room, are the following varieties of air, designated by Italian denominations, viz.—

The *Aria di Carattere* ('characteristic air'), which is distinguished by force and energy of expression, and by dramatic effect. The *Aria Parlante* ('speaking air'), which is rather declaimed than sung, and is best suited to the buffo or comic performer. The *Aria di Cantabile* ('singing air'), a tender, pathetic air, calling forth the expression and taste of the singer. The *Aria di Bravura* ('dashing air'), an air in which the performer displays his powers of execution, and seeks rather to astonish than please.

AIR-CUSHIONS. The mechanical application of common air, in respect of its pressure or elasticity, has been greatly extended within the last few years. Provided a mass of air can be confined within a given receptacle, and that receptacle be of an elastic or yielding character, the air assumes many of the qualities of a soft stuffing or padding, when its quantity is small compared with the size of its envelope; but when the quantity is as great as can be introduced without bursting the envelope, the air becomes nearly equivalent to a solid body. So long as the means were wanting for conveniently making air-tight cloth vessels, this principle was slenderly applied; but the use of caoutchouc or India-rubber, as a glutinous varnish, has developed many ingenious contrivances for this object. When a bag has been made of such material, rendered also air-tight by somewhat similar means at the seams, air may be passed into it as a substitute for more solid materials. In practice there are some very neat arrangements adopted in effecting this. Temporary air-seats or cushions are made by forming a bag of air-tight cloth, perfectly enclosed at every part except one corner, where is inserted a small tube and stop-cock, capable of effecting or preventing communication from the interior to the exterior. The cock being opened, and the tube applied to the mouth, air is blown into the cushion, until it expands to the desired degree of fulness; the cock is then closed, and the air remains imprisoned. When not in use, such a cushion can have the air expressed from it, and may then be folded up into a small space.

It is obvious that seats, cushions, pillows, and beds of various kinds, having a similar object in view in relation to softness, fulness, and elasticity, may be made by similar means. When the quantity of air included in an envelope is greatly increased, it may be made the means of producing actual pressure in a more equable way than by any solid bodies. Thus, an air-tight bandage was invented a few years ago, the object of which was to form a wrapper to a human limb under surgical treatment. There is a bandage with straps fitted for being tied round the limb; and when so tied, air is breathed into an air-tight envelope to the bandage, through a small tube provided with a pipe. By increasing or lessening the quantity of air impelled, the pressure of the bandage on the limb may be made so small as to be scarcely perceptible, or may on the other hand be made even painfully close; but in either case it will be equable in every part.

A patent has been obtained, by Mr. Walton, for certain modifications in the mode of preparing air-bags for beds and similar purposes. Hollow balls of India-rubber, filled with air, are enclosed within external coverings so as to form a sheet of balls; and many such sheets may be piled one on another to form a bed or mattrass of any required thickness. Such an arrangement would, however, be very complicated and expensive.

Further illustrations bearing on this subject will be met with under LIFE-BOAT and WATERPROOF COMPOSITIONS.

AIR ENGINES. Many attempts have been made to produce engines which should have the power of steam-engines without the use of steam. The compression or the rarefaction of air, brought about in some one of many different ways, is the agent relied upon for producing a moving force. In 1840 Mr. Stirling patented such a machine, and read a description of it before the Institute of Civil Engineers in 1846. In this engine two strong air-tight vessels are connected with the opposite ends of a cylinder, in which a piston works in the usual manner. About four-fifths of the interior space in these vessels is occupied by two similar air-vessels, or plungers, suspended to the opposite extremities of a beam, and capable of being alternately moved up and down to the extent of the remaining fifth. By the motion of these interior vessels the air to be operated upon is moved from one end of the exterior vessel to the other; and as one end is kept at a high temperature, and the other as cold as possible, when the air is brought to the hot end it becomes heated, and has its pressure increased, whereas its heat and pressure are diminished when it is forced to the cold end. Now, as the interior vessels necessarily move in opposite directions, it follows that the pressure of the enclosed air in the one vessel is increased, while that of the other is diminished; a difference of pressure is produced on opposite sides of the piston, which is made to move from one end of the cylinder to the other. The piston is connected with a fly-wheel, and motion communicated in the usual way. A large bakery has been established on this principle at New York, the machinery being worked by the ascensive force of a current of air heated by the baking ovens. At a certain height within a lofty vertical shaft is a horizontal wheel, with wings or vanes attached at an angle of 10°; the ascending air causes this wheel to revolve horizontally; drums are fixed on the spindle of the wheel, and straps or bands from these drums drive the machinery for grinding the flour and kneading the dough.

Baron Von Rathen made trial of an air-locomotive on a common road, in 1848. It travelled from Putney College (where it was constructed) to Wandsworth, at the rate of 10 or 12 miles an hour. The air-reservoir (substitute for a steam boiler) had a capacity of 75 cubic feet; it was capable of being charged with air to a pressure of fifty atmospheres, by a 6-horse power engine.

An air-engine of peculiar construction was employed in 1851, in the Govan Colliery, near Glasgow, invented by Mr. Randolph. There were circumstances connected with the shape and arrangement of the shafts of the mine which rendered the supply of steam difficult; whereupon Mr. Randolph, acting on a suggestion made by Mr. David Elder, contrived the air-engine. He makes use of compressed air, supplied by a compressing steam-engine at the surface, and conveyed down by a pipe to work an engine at the top of the second shaft, in the manner of a non-condensing steam-engine; the discharged air being thrown into the workings to aid in the ventilation of the mine. The air-engine, supplied by the compressing apparatus, is employed for working the winding and pumping apparatus of the second shaft. The compressed air is conveyed to it through a cast-iron shaft 10 inches in diameter, carried down the main shaft. At a meeting of the Institution of Mechanical Engineers, in 1857, it was stated that this machine had been working admirably for six years, and had illustrated many points connected with the useful employment of air-engines.

There are certain forms of air-engines, especially Ericsson's, which will be better noticed under Caloric Engine.

AIR-GUN. An instrument for projecting bullets, in which the moving power is the rush of condensed air allowed to escape, instead of the formation of gases arising from the ignition of gunpowder. The air-gun and the common gun are therefore the same in principle.

In the stock of the gun is a condensing syringe, the piston of which condenses air into a cavity, which has a valve opening inwards, just behind the bullet. The barrel is open, and the bullet (which should just fit it) is inserted in the usual way. The trigger opens the valve behind the bullet, and permits the rush of the condensed air, which propels the bullet. The moment the finger is withdrawn from the trigger, the air closes the valve, and remains, somewhat less condensed than before, for the next discharge.

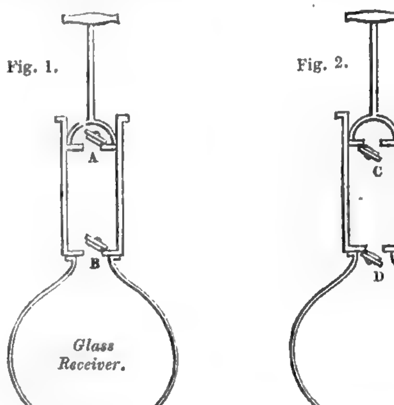
The same principle has been variously applied. In the *magazine air-gun*, there is a reservoir of bullets, in a channel under the barrel, one of which is turned in by a cylindrical cock pierced by a tube, which in one position is a continuation of the reservoir of bullets, and in another, of the barrel. Thus, by turning the gun upside down and turning the cock, a bullet falls into it from the reservoir, which, on re-turning the cock, is of course in the barrel. This is a very primitive application of the now famous principle of the Revolver, or revolving pistol. In some air-guns, the cavity containing the condensed air is a hollow copper ball, which can be screwed on to the gun after condensation. The *air-cane* is so called because it is usually in the form of a walking-stick. The handle contains the condensed air, and can be unscrewed and filled by a separate condensing syringe. There is some mention of an instrument similar in principle to the air-gun among the ancients; and it is said that Ctesibius, a celebrated mechanical philosopher, who lived, B. C. 120, at Alexandria, constructed an instrument, in which the air, by its elastic force, discharged an arrow from a tube. (Montucla, 'Histoire des Mathématiques,' vol. i. p. 267.) The invention, such as we have described it, is ascribed to Marin, a native of Lisieux, in France, who is said to have presented an air-gun to Henry IV.

Shaw's air-gun, patented in 1849, combines an endless band of vulcanised india-rubber with an air-exhausting apparatus. The elasticity is so applied as to compress the air by a single stroke of a syringe or air-pump, the moment before the discharge. The operation performed by the sportsman, to bring the apparatus into a charged condition, is very similar to that adopted in the use of the cross-bow.

Down to the present period, however, the air-gun, in all its forms, has been little other than a mere toy. No power, but only an adaptation of power, is gained by its use; for the condensation of the air itself requires force. The air-gun has never been used in war, on account of its expense, and the force which must be employed to condense the air. The *steam-gun*, exhibited in London a few years ago, exemplified a much more forcible agent than air for the propulsion of bullets; but nothing has hitherto been accomplished to render that mechanism practically available, although suggestions to that effect were made during the Russian war of 1854-5.

AIR-PUMP. A philosophical instrument for removing the air out of a vessel. We shall also include under this head the apparatus for forcing more air into a vessel, better known by the name of the *Condensing Syringe*, as the two differ very slightly in their main principle and simplest construction.

Fig. 1. Fig. 2.

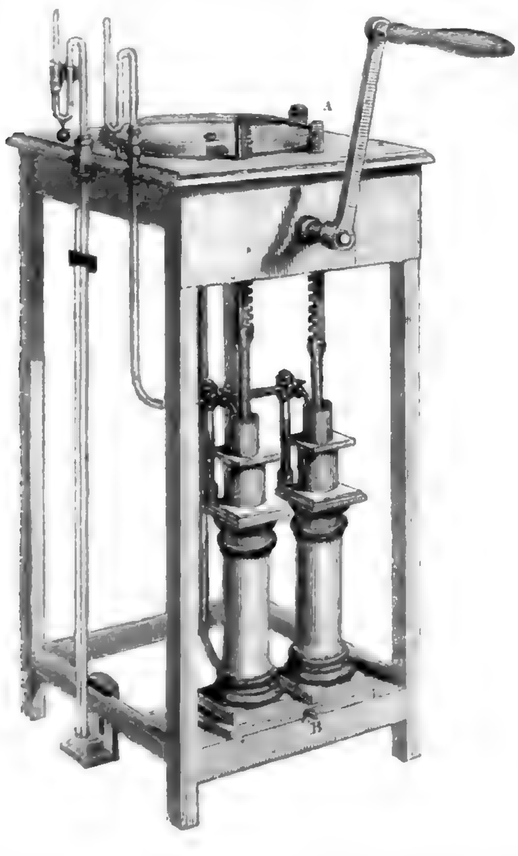


Above we have the sections of the simplest forms of an *exhausting* and of a *condensing* syringe. Both consist of a brass tube or cylinder, closed at one end, excepting an orifice to which a valve or lid is attached. A piston, with a rod and handle, enters at the other end, and can be moved up and down the tube. The piston is not entirely closed, but has a valve opening the same way as the other valve. Both are attached to vessels the air of which is to be rarefied or condensed. In fig. 1, or the exhausting syringe, both valves open upwards, or let air only *out* of the vessel and the piston: in fig. 2, or the condensing syringe, both open downwards, or let air only *into* the vessel and through the piston.

Let the whole contents of each vessel be, for example, six times that of the tube of the syringe, and let both pistons be pushed down. We first take the exhausting syringe. The instant the piston begins to rise, there is no air between A and B; the valve A is kept shut by the pressure of the exterior air, while the air in the vessel, pressing on B from underneath at the rate of about fifteen pounds to the square inch, raises it, and the air in the vessel is thus distributed between the vessel and the tube. If we call the tube one *measure*, the vessel is six *measures*; so that the air which occupied six measures now occupies seven, or is only six-sevenths of its former density. When the piston is returned again, the air in the tube is compressed, but cannot return into the vessel, because B does not open inwards. By the time the piston has returned through one-seventh of its descent, the equilibrium between the air in the tube and the external air will be re-established;

and by the time the piston has descended so much farther that the additional elastic force acquired from compression will suffice to lift the valve A, the latter will open, and the air will rush out. This continues until the piston has quite returned to B. That is to say, after every stroke of the piston, the air in the vessel has only six-sevenths of the density which it had before the stroke, since the air contained in six measures is expanded into seven by the rise of the piston. Therefore, at the end of the second stroke the density is $\frac{6}{7}$ of $\frac{6}{7}$, or $\frac{36}{49}$, that is, 36 measures of common air would weigh as much as 49 of the air we have now got inside the vessel. At the end of the third stroke the density is $\frac{6}{7}$ of $\frac{36}{49}$, or $\frac{216}{343}$. Without going farther, suffice it to say, that at the end of the twentieth stroke, the density of the rarefied air is about $\frac{1}{22}$; and at the end of 100 strokes, it would take about five million of measures of the rarefied air to weigh as much as one of common air. But long before this time a limit would be put to the exhaustion, in the present state of the apparatus. The air in the vessel cannot escape into the tube unless it has force sufficient to lift up the valve B; which after a certain number of strokes will not be the case, for the elastic force of the air diminishes in the same proportion as its density, being at first fifteen pounds to the square inch; so that by the time the density is reduced to $\frac{1}{480}$, the valve, if it present a surface of one square inch, will not rise, if it be so heavy as half an ounce. Let us, then, suppose B to be fastened to the piston by a loose string, so long that it becomes tightened just before the piston reaches its greatest height. The string will then open the valve, and the rarefaction will take place as usual.

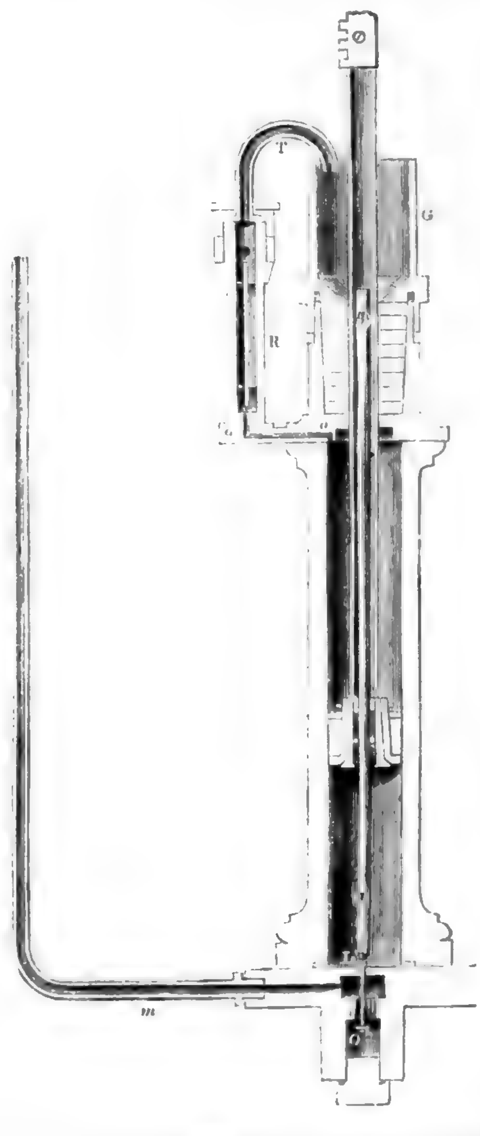
The condensing instrument will now be easily understood. Let the piston be raised, the valves will then be open; but the moment the piston begins to descend, the rush of air outwards will shut C, and the whole of the air in the tube will be forced into the vessel, which admits it, since D opens inwards. If this be done quickly, so that hardly any air escapes, seven measures of air, after the stroke, will occupy the space filled by six measures before it, so that the density of the air in the vessel will be $\frac{7}{6}$; or six measures of condensed air will weigh as much as seven of common air. When the piston returns, air rushes in through C, and presses the valve D, which nevertheless, unless made too heavy, does not open, because it is pressed with a greater force from within. In every succeeding stroke an additional measure of common air is added to the stock already contained in the vessel. At the end of the second stroke the density is $\frac{8}{6}$, at the end of the third $\frac{9}{6}$, and so on. Every succeeding stroke will be more difficult,



for the air contained between C and D in the descent of the piston, will not force D open until it is more compressed than the air within the vessel. Also the condensation increases only in arithmetical progression, while the corresponding rarefaction in the exhausting syringe takes place in geometrical progression. It would take 30,000,000 of strokes, all but one, to produce a condensation, the corresponding rarefaction to which is gained in a hundred. It is needless to say, that no materials that we could put together would bear such a pressure, and no force that we could exert would create it.

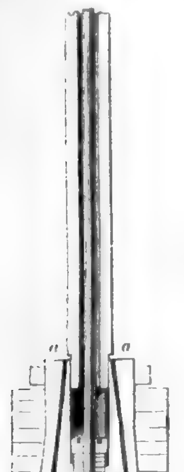
The exhausting syringe, as above described, is, in principle, the common air-pump. We shall now proceed to describe Cuthbertson's air-pump, containing the most recent material improvements.

The circular plate or *table* at the top is of metal or of glass ground to a perfect plane surface, on which is placed an inverted glass jar, from which the air is to be exhausted, called the *receiver*, the bottom of which is also carefully ground: so that if the plate be slightly smeared with grease and the receiver placed upon it, the junction of the two is air-tight. The hole in the middle of the plate is the end of a tube, which extends vertically downwards, until, curving at the bottom, it passes through the front beam below the barrels, with the interior of each of which it communicates. These barrels are exhausting syringes, the construction of which will presently be more particularly described: they are worked by rack-work, communicating with a cog-wheel and handles, space for the racks to play being cut in the upper wood-work of the apparatus. On the left are the gauges for ascertaining the degree of exhaustion obtained, and at A is a place for a PEAR-GAUGE. See also SYPHON-GAUGE, as we shall here only describe the most common, the *barometer-gauge*. The box attached to the under beam on the left contains mercury, out of which rises a tube and a graduated scale, as in the barometer. This tube passes through the higher wood-work, and also ends in the orifice which is in the middle of the plate, so that the communication being free, the air in the receiver, and that in the tube above the mercury, are in the same



state. Hence as the air is rarefied, the external air will force some mercury up the tube, and the height to which it has risen will show the degree of rarefaction. For example, suppose the common barometer to be 30 inches high, while the barometer-gauge of the air-pump stands at 20 inches. If the vacuum were complete, the barometer-gauge would be a common barometer, and would stand at 30 inches: but as it stands only at 20 inches, the pressure of the air in the receiver is equivalent to 10 inches of mercury, or one-third of that of the exterior air. Therefore the density of the air in the receiver is one-third of that of the exterior air, or two-thirds of the air have been removed.

The preceding cut shows a section of the piston rod, as well as of the barrel. The tube *m* comes from the receiver, and air can be admitted by it into the barrel, when the rod *gg* is raised. The rod *gg* passes into the piston-rod (which is hollow), and works stiffly in it, being however unconnected with it except by friction. This rod consists of two parts, above and below L, the latter of which is not thick enough to fill the orifice in which it plays. But when the piston descends, the conical juncture of the thicker and thinner parts is brought upon this orifice, and shuts it close. After this, and during the rest of the descent, the hollow piston-rod slides downwards upon the rod *gg*. As soon as the piston begins to ascend, the rod *gg* is raised with it, owing to the friction, so far as the nut O will let it rise, after which the piston-rod slides up *gg*. We have here the lower valve of the exhausting syringe, shut during the descent of the piston, open during the ascent, and not opened by the force of the air from underneath, so that the functions of the string which we supposed in our first exemplification are performed. A little higher up the barrel we find the piston, as better shown in the adjoining figure. The external part is a partial piston not connected with the piston-rod, but fitting closely to the barrel. The piston-rod, when rising, fits this exactly, renders it air-tight, and causes it also to rise. But when the piston-rod is descending, it will not cause the descent of the exterior, and, as we have called it, partial, piston, until the projecting shoulders *aa* (in the figure) come upon it; and, as these shoulders do not go all the way round, the piston in descending is not air-tight. This apparatus supplies the place of the upper valve, being air-tight in the ascent, but not so in the descent. Looking above the piston, we find that its rod works in metal shoulders, the interval between which is occupied by stiff leathers. The space above the leathers opposite to G is filled with oil, which is communicated slowly to the leathers, and also to the barrel beneath. From the latter, however, it is immediately expelled by the rise of the piston, which forces it, as well as the air in the barrel, through the channel *aa*. The oil and the air then force up the rod in the cavity B, which rod, working in collars, answers the purpose of a valve. The oil is there lodged, until it is collected in sufficient quantity to flow again into the reservoir at T. The air escapes into the exterior atmosphere.



Having shown that we have here an under valve shut during the descent, and open during the ascent, with an upper valve open during the descent and shut during the ascent, we need not repeat the manner in which the rarefaction is produced. We have only further to notice, that a branch from the main tube which enters the receiver is carried through the under wood-work in front, and emerges at B. It is here stopped by a screw; but when the operator desires to restore the air under the receiver, he opens this screw, upon which the communication between the exterior atmosphere and the receiver is restored, and the air rushes in. In the perspective figure, a cross bar, in which the upper parts of the barrels are inclosed to strengthen them in their position, is omitted for the sake of clearness.

We give in the following figure a representation of a more portable and less expensive species of air-pump, which, after what we have said, will need no description.

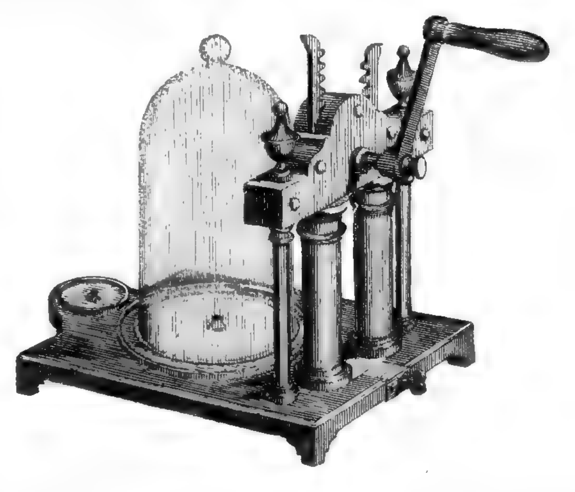
The small plate behind the receiver is for another small receiver, in which a gauge is placed. This guage is nothing more than a common barometer, which falls with the diminution of pressure from the air in the receiver, in the same way as the common barometer when the pressure of the exterior air is lessened by a change of weather.

The following experiments are among the most common of those shown with the air-pump:—

1. If the receiver be open at both ends, and the upper orifice be stopped by the hand,—on exhaustion the pressure of the exterior air will prevent the removal of the hand. If a piece of bladder be tied tightly over the orifice, as the exhaustion proceeds the bladder will be pressed inwards, and will finally burst with a loud report. The pressure of the air is also proved by the experiment of the hemispheres, described in the article AIR.

2. The weight of the air is proved by exhausting a copper ball furnished with a stop-cock, which is shut before the ball is removed from the air-pump. It will then be found to weigh less than before the exhaustion was made.

3. The presence of air in various substances may be detected. A glass of liquid placed under the receiver will give out bubbles of air as



soon as the exhaustion begins. A shrivelled apple will be restored to apparent freshness by the expansion of the air which it contains, but will resume its original appearance when the air is allowed to return.

4. The elasticity of air may be shown by placing a bladder under the receiver, not distended, and the mouth of which is tied up. On exhausting the receiver, the air contained in the bladder will expand it more and more, as more of the pressure from the exterior is removed; and the bladder will finally burst from the interior pressure. If a hole be made in the smaller end of an egg, and the egg be then placed in a wine-glass with this end down under the receiver, the small bubble of air which is always found in the larger end, will, by its expansion, force out the contents of the egg. On re-admitting the air, the contents of the egg will be forced back into the shell.

The first vacuum was made by Torricelli [TORRICELLI, in BIOG. DIV.; BAROMETER], but the first air-pump was constructed by Otto von Guericke, who exhibited it publicly at the Imperial Diet of Ratisbon in 1654. It was an exhausting syringe, attached underneath to a spherical glass receiver, and worked somewhat like a common pump. The syringe was entirely immersed in water to render it air-tight. Shortly afterwards, Boyle constructed an air-pump in which the syringe was so far improved that the water could be dispensed with. He also first applied rack-work to the syringe. The second syringe and the barometer-gauge were afterwards added by Hawksbee, and several minor improvements were made by Gravesande and Smeaton. All the alterations which have been made since the time of the invention, however important, relate to the mechanism only, and not to the principle on which the pump acts.

In the Great Exhibition of 1851, among the instruments exhibited in Class X., the best air-pump was by Mr. Newman. It has a ground-glass plate, and is furnished with two pumps with metal valves, on one of which are two barrels, open at the top. By this arrangement the receiver may be quickly exhausted to 0·4 inch or 0·5 inch. The other pump has a single barrel, with an oil-cistern at the upper part, and the air is lifted through a valve at the bottom of this cistern. "If anything re-enters the barrel it can only be oil, which is brought out with the air at the next up-stroke of the piston. The piston has a metal valve; but the opening of this valve is not necessary to the continuation of the exhaustion, as the piston at its lowest point passes below the aperture leading to the receiver. This construction of air-pump exhausts more thoroughly than any yet known." ('Jury Report.') In some experiments which were tried with this pump, the reading of the barometer at the time was 30·08 inches, while the gauge of the pump stood at 30·06 inches.

A pump exhibited by Messrs. Watkins and Hill, on a plan suggested by Mr. Grove, has oil-silk valves, and is so constructed as to leave the least possible residue of air in the valve after each stroke of the piston. "The piston is solid, without a valve, and the shape of its lower part is an obtuse cone. Part of this cone rises at the top of each stroke above the aperture leading to the receiver; and the air which has entered the barrel is, by the down-stroke, forced through a valve at the apex of the hollow cone terminating the lower end of the barrel, to which the lower end of the piston fits very accurately. The piston-rods pass through air-tight leather collars in the tops of the barrels. This pump exhausted the air till the elastic force was only 0·05 inch of mercury."

Mr. Siemen's air-pump was exhibited by Knight and Sons. "It consists of two cylinders of different diameters, the smaller one placed below the larger, and separated from it by a plate forming the bottom of the upper and the top of the lower cylinder. A piston-rod, common to both cylinders, passes through a stuffing-box in the plate, attached to which are two valved pistons, working in their respective cylinders. The advantage of this construction is, that the pressure of the external air on the oiled silk valve of the larger cylinder is taken off by the vacuum formed in the smaller one, and in consequence no greater resistance is offered by the valve than that arising from its adhesion and tension. The exhaustion of this pump is very rapid, and in the trial amounted to 0·24 inch of mercury." The motion of the pistons is effected by means of a short crank with a jointed connecting-rod, converting the circular motion given by the lever handle into a vertical one, which is maintained by means of a cross-head with rollers working between guides. This pump is more particularly described in Mr. Tomlinson's 'Rudimentary Treatise on Pneumatics.'

In the air-pump exhibited by Varley and Sons a new construction is adopted. "It is worked by a continuous rotatory motion of the handle, slide-valves being used to open and close the communication. On the piston arriving at one end to expel air from the barrel, it is followed by rarefied air from the receiver; the slide-valve closes upon the receiver and connects the two sides of the piston; the residual air expands into the larger space, becomes equally rarefied, and the subsequent motion of the valve separates these spaces, and connects the receiver with the closed end. The piston then returns to exhaust air into this end of the barrel and to expel it from the other, and thus continuous exhaustion is kept up; for, how rare soever the air becomes, it keeps flowing after the piston continually. The barrel is twice filled for every entire revolution of the handle. This pump has a single barrel with double action; it exhausts quickly, and the exhaustion was found to be 0·05 inch for a moment, but could not be maintained."

In the French department, the double-barrelled air-pump exhibited by M. Breton had, instead of valves, a glass plate sliding over apertures communicating with the receiver, and the pumps and the motion of this glass plate is produced by the mechanism which works the pump. "The approximate exhaustion is first made by the ordinary alternate action of the barrels. The system of communication is then changed by shifting round the glass plate, which serves as a valve during one-fourth of a revolution, when the rarefied air is condensed in one barrel and sucked into the other, whence it is ultimately ejected through a valve of oiled silk very close to the piston." In the air-pump exhibited by M. Deleuil, the barrels were of glass, and the valves, after M. Babinet's plan, were opened by means of wires passing through the pistons. The opening of the valves is thus rendered independent of the elastic force of the air left in the receiver, and the degree of exhaustion must depend on the air remaining after the action of the piston.

AISLE, or AILE (in Architecture), indirectly from the Latin word *ala*, a wing, through the French *aile*, which has the same signification. In French, this term is applied to the outlying and returning ends of a building, which we distinguish by its English equivalent, *wing;* such are the columned ends of the front of the British Museum. We apply the term aisle to the lateral divisions or passages of the interior of a church—those parts which lie between the flank walls and the piers, pillars, or columns, which flank the nave, or grand central division—when the structure is so arranged. Sometimes, but incorrectly, with reference to modern churches and chapels in this country, the mere passages or corridors which run between, and give access to the pews, are called aisles. Still more incorrectly, some writers, and even ecclesiastical writers, have called all the longitudinal divisions of the body of a church, aisles, thus including the nave under a designation which belongs only to its adjuncts and accessories.

The division of a church into what we term nave and aisles arose simply out of the difficulty which existed of spanning a great breadth with a roof without some intermediate support; and thus the greater Constantinian churches or basilicas of Rome were built with four rows of columns, forming five longitudinal divisions; that is, with two aisles on each side of the nave. This was imitated in subsequent structures, and the metropolitan churches of Milan and Paris were built in five divisions, or with four aisles, as they exist at the present time. That the custom of arranging the interiors of churches with aisles was continued in deference to ecclesiastical precedent, or at any rate long after the necessity for using the props which form them ceased architecturally, may be rendered clear by reference to the following fact. Most of our cathedrals and greater churches in this country are of later date than the roof of Westminster Hall, which, without intermediate support, spans a greater breadth than most of them can boast of; and yet they are, as a general rule, all divided into nave and aisles. In recent Gothic churches it is needless to add they are continued, even when, as in some of very small size, they are at once obstructive and costly.

In some English books, though perhaps in none of the present century, this term will be found written without the a—*isle*.

ALANINE ($C_6H_7NO_4$). When aldehyd-ammonia is acted on by hydrocyanic acid, and an excess of hydrochloric acid, a crystalline body, soluble in water, is formed, to which Strecker has given the name alanine. It crystallises in groups of prisms, which are insoluble in ether, nearly so in alcohol. Its solution has no effect upon test-papers. It sublimes at about 400°. It is homologous with *glycocoll* and *leucine*, and isomeric with *lactamide*, *urethane*, and *sarcosine*. When acted on by hyponitrous acid it is converted into lactic acid, as follows:—

$$2(\underbrace{C_6NH_7O_4}_{\text{Alanine.}})+2NO_3=2HO+4N+\underbrace{2HO,\ C_{12}H_{10}O_{10}}_{\text{Lactic Acid.}}.$$

ALARUM. It is curious to mark how much ingenuity has been displayed within the last few years in the invention of alarums, and how many patents have been taken out for the inventions. In most of these contrivances there is some little bit of mechanism which gives a shrill sound whenever attention is required to be directed to any subject with which the alarum is associated.

Without describing any of the older forms, we may glance at a few of the modern suggestions. The 'travellers' alarum' is a small brass box about 2½ inches in diameter by 1¼ thick. It has hands which may be set to any hour to awaken a sleeper. Mr. Allen, in 1844, registered an alarum intended to prevent injury to boilers from the water falling below its proper level; it consists of a float within the boiler, a steam-whistle on the exterior, and a tube of connection; when the water is at a proper height in the boiler, the float is buoyed up, and the whistle is silent; but when the water, and with it the float, descend too low, a little valve in the tube opens, and a current of steam from the boiler ascends to the whistle, which immediately gives forth a shrill sound, thereby indicating that the water has sunk too low in the boiler.

An alarum patented by Mr. Doull, is a 'railway whistle,' so constructed as to yield several notes, capable of being combined into a code of signals. A 'chemical alarum' by Mr. Mowbray consists of a copper cylinder, with a whistle at the top; a piece of carbonate of lime and a little muriatic acid are put into the cylinder, by which carbonic acid gas is speedily generated; and this is forced by some kind of mechanism into the whistle, whenever a sound is required to be produced. A contrivance by Mr. Hoare, described before the Society of Arts, consists of a chain of rods extending from end to end of a railway train, and moving freely on joints; at the end of the chain, in the guard's carriage, is a crank which, when the rods rotate on their axes, comes in contact with a hammer, and causes it to strike a bell; the driver, or the passengers in any carriage, can give a slight rotatory motion to the rods, and thus signals may be communicated. Up to the present time, however, all kinds of railway train signals have been sadly neglected. See further on this subject under RAILWAY.

But the busiest contriver of alarums, perhaps, is Mr. Rutter, who has called to his aid the marvels of electricity. In a patent for several such contrivances, taken out by him in 1847, one variety is the 'Fire Alarm', a complicated apparatus intended for use in large buildings. A galvanic battery is placed in one room, the alarum in another, thermometers in every room, and copper wires to connect all these pieces of apparatus. If the temperature of any room be greatly raised, as by accidental fire the rising mercury in the thermometer comes in contact with a metallic wire, which sets the galvanic battery in action, and this again works the alarum-bell in the same way as an electro-telegraphic clock, but with an adjustment intended to show in which room the rise of temperature has occurred. A second variety, the 'Trespass Alarum,' depends for its action on the placing, near every door and window, of a tube containing mercury, open at the top; the opening or closing of the door or window brings a small wire into contact with the surface of the mercury, and this completes a galvanic connection with a battery in another room: all the parts of the apparatus may be the same as those in the fire alarum, except by having open tubes of mercury near doors and windows, instead of thermometers in each room. A third variety, the 'Railway Alarum,' is intended to establish signals of communication between the guard and the engine-driver of a railway train. There is a copper wire carried through or upon or beneath each carriage, and connected with another in the adjoining carriage by a flexible metallic cord: the wire and cord being coated with gutta percha to secure isolation. There is thus a wire communication from end to end of the train. The guard has in his box or seat, a very small galvanic battery; and the engine-driver has a series of small studs connected with the rail on which his hand is usually resting. When the guard wishes to communicate with the engine-driver, he sends a slight galvanic shock through the wire to the spot on which the hand of the driver rests; and the duplication or variation of the shock may be made to indicate various signals.—It must be evident that great completeness and exactness would be necessary to render any of the above three kinds of alarum efficient for the purpose intended; and it may be added that, as yet, the contrivances have not come into actual use.

A floating alarum was suggested a few years ago by Mr Hobbs, of Bristol, to be moored to a sunken rock or other dangerous place at sea. The centre of the machine is an air-vessel or buoy. At each end is a box in which a whistle is fixed, whose mouth is protected from the water. As the water of the sea circulates in certain parts of the interior of the machine, it drives the air alternately from one end to the other, and impels it through the whistles; and the more violently the sea rocks the floating machine, the louder will the whistles give forth their sound. The proposal of the inventor is to make the buoy and whistles of such dimensions that the sound may be heard some miles distant. [BUOYS.]

ALBATA, is the name given to one of the numerous varieties of white metal, now so largely used in many branches of manufacture at Birmingham. Different mixtures or alloys will produce a white metal. For example, Mr. Parker obtained in 1844 a patent for five such compounds, all having the properties of whiteness and considerable malleability. One consists of zinc, tin, iron, and copper, in certain specified proportions; another of zinc, tin, and antimony; a third of zinc, nickel, iron, and copper; a fourth of copper, nickel, and silver; and a fifth of nickel, iron, and copper. It seems evident from the specification, that many different proportions of the ingredients may be adopted, in each of the above kinds. The mode of making white metal, of zinc 50, tin 48, iron 1, and copper 3, is thus described:—the iron and copper are first melted together in a crucible, and while in a fused state, the tin is added in such quantities at a time that the iron and copper shall not become solid; the zinc is then added, and the whole well combined by stirring. The flux is composed of one part of lime, one part of Cumberland ore, and three parts of sal-ammonia. The alloy thus produced may be cast in sand or ingots for rolling. The 'nickel-silver,' which has recently come largely into use, is a cheap substitute for silver, superior in many respects to albata, and having the metal nickel as one of its components.

See further in respect of these compound metals under ALLOY.

ALBIGENSES, a religious sect, which appeared in the South of France in the twelfth century, and was the object of long and cruel persecutions and wars. The denomination of Albigenses has been used by historians and other writers in two senses, and often indiscriminately. In its more restricted and appropriate sense, the Albigenses were a branch of the Paulicians from the East, who, being persecuted by the Greek emperors and clergy, took refuge during the eleventh century in Italy, from whence they spread into the South of France, Spain, and other countries. They were called in Italy, Cathari, or "pure;" also Paterini, from a place in Milan where they held their meetings; and Gazari, from Gazaria or Lesser Tartary, the country from which they came; they were called, in France, Bulgares, for a similar reason: and afterwards Albigenses, from Albiga, Albi, the town where their tenets were condemned by a council in 1176. But the Cathari were divided into two sects, one of which held the old Manichean doctrine of two eternal beings, one the God of Light, who was the Father of Jesus, and the other, the Principle of Darkness, who was the creator of the material world. This sect was also called Albanenses. The other division of the Cathari believed in one eternal principle, the Supreme God and Father of Christ, by whom the first matter was created; until the Evil Being, after his rebellion against God and his subsequent fall from heaven, arranged this original matter according to his own fancy, and gave it its present form and attributes. They believed that human bodies in particular were the production of the evil principle. The Albigenses belonged to this latter sect, which was also called Bajolenses or Bagnolenses. They had bishops, vicars, and deacons; they preached abstinence, mortification, and celibacy; their community, however, was divided into two classes, the Consolati, or "comforted," who lived in perpetual celibacy, abstained from meat and wine, and practised other austerities; and the Confederates, who, being unable to endure this mode of existence, lived apparently like the rest of the world, but bound themselves to enter before their death into the class of the "Comforted" by a ceremony of inauguration. But, in the more extended sense, the name of Albigenses was given in the twelfth and thirteenth centuries, not only to all the Cathari indiscriminately, but also to the other sects which existed in the South of France at the time, including the Waldenses, who were very distinct in their tenets from the others, and had no taint of Manicheism in them. They all agreed, however, in considering the authority assumed by the Popes in spiritual matters, as well as the discipline and ceremonies of the Roman Church, as unlawful and erroneous. Pope Innocent III. sent two legates, Peter of Castelnau, and one Rainier or Raoul, both Cistercian or Bernardine monks, as his legates to France, in order to extirpate all these heresies. Dominic, a Spaniard, and the founder of the order of Preachers, returning from Rome in 1206, fell in with the legates, and volunteered his services in the same cause. These champions, who, without asking for the advice or the concurrence of the local bishops, and upon the sole authority of the Pope, inflicted capital punishment on those heretics whom they could not convert by argument, were called, in common discourse, 'Inquisitors;' but the famous tribunal of that name was not established until 1233, by Gregory IX., who entrusted it to the Dominicans. In 1208, Castelnau, one of the legates, who had become odious by his severities, was murdered near Toulouse; and Innocent III. on this proclaimed a regular crusade against the Albigenses, and against Raymond VI., Count of Toulouse, who supported them. All the French barons were summoned to take the field; and Simon, Count of Montfort, was appointed chief of the expedition, under the direction, however, of Arnald, Abbot of the Cistercians, and the Pope's new legate. The war began in 1209, and lasted many years, attended by circumstances of the greatest ferocity. At the taking of Béziers a general massacre of the inhabitants began. The legate being asked by some of the military leaders how they were to distinguish the Albigenses from the orthodox Catholics, of whom there were many in the town,—"Kill them all," was the reply; "God will find out his own." Montfort lost his life at the siege of Toulouse, in 1218 and Raymond, his adversary, died in 1222. The war, however, was resumed by the sons of the two antagonists; until Pope Honorius III., alarmed at the successes of Raymond VII., induced Louis VIII., King of France, to take the field in person. At last the Count of Toulouse, pressed on all sides, made peace with the King in 1229. This was a mortal blow to the Albigenses. The Inquisition was now permanently established at Toulouse to try those heretics who had escaped the sword. Raymond himself died some years after; and in him the house of the Counts of Toulouse became extinct, and its territories reverted to the French crown. The extermination of the Albigenses in the South of France was complete; the country was devastated; and the language and poetry of the Troubadours became also extinct, the bards themselves being obliged by the terrors of the Inquisition to fly to other lands. Langlois, a Jesuit, has written a 'History of the Crusade against the Albigenses;' but a better account of them is found in the 'General History of Languedoc,' published at Paris in 1730.

AL BORAK, the name of an imaginary animal, on which, according to a Mohammedan tradition, considered as a dream by some, the Arabian prophet performed his journey from the temple at Jerusalem through the heavens. It is conceived by them to have been of a middle stature and size between that of a mule and of an ass, and to have received its name in allusion to the shining whiteness of its colour.

ALBUM, a Latin word, signifying any thing white. The prætor's album was probably a board, either having the surface or the letters white, on which the acts and edicts of that functionary were inscribed and publicly exhibited. The opinion of some writers, who have supposed that it was the room or place where such notices were hung up, is undoubtedly erroneous. Among the later Latin authors we read of the album of the judges, the album of the senators, and even the album of the citizens, which seem to have been books or registers in which the names of persons of those orders were enrolled. In the middle ages we find album, and albus, and albo (as an indeclinable noun), used for a register of saints, a muster-roll of soldiers, or, in general, any list or catalogue of names. Album also sometimes signifies a letter or epistle, in allusion to the white surface of the paper or parchment. (See the 'Glossaries' of Ducange and Carpentier.) An album, in modern times, is a book appropriated usually to receive the autographs or other manuscript contributions of authors, travellers, or any other person of whom it is thought worth while to collect such memorials; but sometimes, also, merely as a repository of drawings, prints, verses, and other miscellaneous fragments. On the Continent, the matriculation list and the black board at the universities have received this name; and the note-book of a tourist, in which he makes on the spot his memoranda of places and occurrences, is often called his album.

ALBUMEN. A member of the group of substances known as the *albuminoid* or *protein* group. There are *albumen*, represented by the white of egg and the serum of blood; *fibrin*—the muscular tissue of animals; *casein*—found in solution in milk, and forming the basis of cheese; and *legumin*, existing in the seeds of all leguminous plants. To these may be added *globulin* and *vitellin*.

The chemical composition of the varieties of the protein compounds is nearly identical, the ultimate analysis of albumen differing but slightly from that of the others. The following is by Mulder:—

Carbon	53·48
Hydrogen	7·02
Oxygen	22·00
Nitrogen	15·55
Phosphorus	1·55
Sulphur	0·40
	100·00

Casein contains no phosphorus.

Mulder considers that albumen, fibrin, and casein are compounds of a fundamental principle—*protein*—with different proportions of phosphorus and sulphur. This substance, however, to which the formula $C_{36}H_{27}N_4O_{12}$ has been assigned, has never been obtained free from sulphur.

As the animal body is composed to a large extent of muscular and fibrous tissues (fibrin), so it is impossible for an animal to exist on food that contains no protein principle; and Liebig considers that such azotized matter in the food is assimilated directly in the process of digestion by the animal, constituting muscle, nerves, &c. The proteic are sometimes termed the plastic elements of nutrition, in distinction from the respiratory elements.

Albumen forms a constituent both of the animal fluids and solids. Of the animal fluids, it forms an essential part of the serum of the blood; it abounds in the fluid that moistens the surface of the internal cavities of the body and of the organs they contain, and it exists in large quantity in the watery fluid poured out into those cavities in the disease termed dropsy. In some diseases it is met with in the urine. In the animal solids it forms the principal part of all membranes; of the skin, of fibrin, the basis of muscle or flesh, and of the organs called glands.

Albumen then exists in the animal body in two states, in the fluid and the solid form. The best example of fluid albumen is the white of egg. The white of egg consists entirely of albumen held in solution in water, and combined with a small quantity of saline matter. It is, therefore, nearly pure albumen. In this state it is a thick glairy fluid, denser than water, insipid, without odour, mixing readily with cold water, in a large quantity of which it is completely dissolved. Exposed in this fluid form to atmospheric air, it rapidly putrefies; but if a thin layer of it be exposed to a current of air, it dries and is converted into a solid, hard, and transparent substance resembling horn, and in this condition it may be preserved for any length of time without change.

The most remarkable character of albumen is the property it possesses of changing from a fluid to a solid state on the application of heat. This process is termed coagulation. If the white of an egg be exposed to a heat of about 134° of Fahrenheit, white fibres begin to appear in it; if the heat be raised to 160°, the fluid substance is converted into a solid mass; if the heat be still further increased to 212°, it dries, shrinks, and assumes the appearance of horn. In proportion as albumen is diluted with water, it requires a higher temperature to coagulate it; but if water hold in solution only the one-thousandth part of its weight of albumen, the water is rendered opaque by boiling. Before coagulation albumen is abundantly soluble in cold water, after coagulation it is no longer soluble in water.

But heat is by no means the only agent capable of coagulating albumen. Fluid albumen is changed into a solid by alcohol, and one of the readiest modes of obtaining solid albumen is to agitate white of egg with ten or twelve times its weight of alcohol. The alcohol unites with the water which held the albumen in solution, and the albumen is precipitated under the form of white filaments.

Albumen is also coagulated by all the stronger acids, the sulphuric, the hydrochloric, the metaphosphoric, and the nitric, but not by the acetic. It is also coagulated by the metallic salts, such as chloride of tin, subacetate of lead, chloride of gold, &c.; and so delicate a test of the presence of this substance is the chloride of mercury, or, as it is commonly called, corrosive sublimate, that if a single drop of a saturated solution of corrosive sublimate be let fall into water containing only the two-thousandth part of albumen, it will occasion a milkiness in the water, and produce a curdy precipitate. If a slight excess of the mercurial solution be added to the albuminous liquid and heat applied, the precipitate which falls on being dried is found to contain in every seven parts, five of albumen. But the most delicate test for albumen and other protein compounds is the acid liquor obtained by dissolving mercury in its own weight of nitric acid. It gives an intense red with aqueous solution of albumen, and can detect $\frac{1}{100000}$ of this substance. Soluble albumen rotates a ray of polarized light to the left. When pure it has a slightly acid reaction. Alkalies prevent its coagulation, and when coagulated dissolve it. It forms definite compounds with the alkalies—albuminates. The albuminate of potash contains according to Lieberkuhn 5·4 per cent of potash.

White of eggs and serum of blood always contain a small quantity of soda, and Gerhardt considers both substances to contain a definite quantity of bi-albuminate of soda, thus accounting for its soluble form.

That albumen contains a perceptible quantity of sulphur may be observed from the tarnishing of silver spoons that have been used for eating eggs; this being due to a small quantity of sulphide of silver formed on them.

Albumen, from its property of coagulating by heat, is of great use in the clarification of liquids. The albumen, as it is rendered solid by the application of heat, entangles all the substances not held in solution by the fluid, and carries them with it to the surface in the form of scum.

But the most interesting application of albumen is its employment as an antidote against one of the most deadly of the mineral poisons. Corrosive sublimate, or chloride of mercury, is scarcely second in the virulence and certainty of its poisonous properties to arsenious acid itself. For this poison, albumen (white of egg) is an effectual antidote, if administered before the poison is absorbed.

ALCAIDE, or ALCAYDE, a Spanish word derived from the Arabic *káyid*, from the verb *káda*, which means to *head*. The *alcaide* was formerly the governor of a fortress or a castle, and also the keeper of a jail. This name is frequently mistaken by foreigners for that of *alcalde*. The offices of these two functionaries however differ very widely, as the one is a military officer, and the other a civil magistrate. (Covarrubias, *Diccionario de la Academia*.)

ALCALDE, in Spain, is a judge appointed by the government or elected by the towns to administer justice within the district under his jurisdiction. The word is a corruption of the Arabic *El-Cadi*, which means judge or governor, or, according to Alcalá, from *Cahid*, which comes from the root *calede*, to preside. There are several denominations of *alcaldes*. The *Alcalde de Alzadas* is a judge appointed by the government, or the lord of the district, to whom the parties may appeal from the decision of the *Alcaldes Pedaneos*, or justices of the peace. The *Alcaldes de Casa y Corte* is a bench of judges, who singly or jointly try all criminals within the court and twenty miles from it, or sixty in cases of robbery. From the decisions of one of these alcaldes an appeal may be made to their tribunal. When the king travelled, one of these alcaldes was formerly obliged to assist the mayordomo in fixing the price of provisions on the road. In the chancillerias of Valladolid and Granada the criminal judges are called *Alcaldes de Crimen*, to distinguish them from the civil ones called *Oidores*. The limit of their respective jurisdiction is the Tagus,—that is, those of the Valladolid take cognisance of all criminal cases on their side of the Tagus, and those of Granada on the other.

The *Alcalde Mayor* is a judge appointed by the king or by the lord of the town to act as an assessor to the *Alcaldes* or *Corregidores*, who are not men of the law. The *Alcaldes Pedaneos* are elected by the people yearly; they preside at the common council, or Ayuntamiento, and act as magistrates. The parish officers are also called *Alcaldes*, and are distinguished by appellations expressing their office, such as *Alcaldes de Barrio*, or parish, *de Calle*, of the street, *de Noche*, of the night, because they patrol and watch during the night. As there is no jury in Spain, all the judges both give the verdict and pronounce the sentence. It is however worthy of observation, that in the *fuero* of Toledo, granted in 1083, it was ordered that all the cases should be tried by the book of the judges, in the presence of ten individuals of the most worthy and most wise of the city elected annually, who were always to sit at court with the judge. A sort of jury existed formerly in the Balearic Islands, but so beneficent an institution no longer remains in any part of the peninsula.

(*Diccionario de la Acad.*; Garibay; Covarrubias.)

ALCA'NTARA, THE KNIGHTS OF (*la Caballeria de Alcántara*), a military and religious order of Spain, so called from the town upon the Tagus. About the year 1156, Ferdinand II. received from his father the kingdom of Leon, with Galicia and Asturias. Of the first of these, a large portion was in possession of the Moors, especially the valley of the Coa, a river which, passing near Almeida, runs northward into the Douro. In this state of things, two brothers, with a body of knights from Salamanca, seized a hermitage in this valley called San Julian del Pereyro, which they converted into a fortress. Distinguished by their courage and success against the Moors, they were constituted by the Bishop of Salamanca a half religious, half military order of knights, under the rule of Saint Benedict; and the institution was confirmed by Pope Alexander III. in 1177. When Alcántara was recovered from the Moors in 1213 by Alonzo IX. of Leon, the defence of it was ultimately assigned to the knights of San Julian del Pereyro. This title was soon absorbed in that of Alcántara. Thirty-seven masters in succession commanded the noble order of Alcántara; and, like those of Calatrava and Santiago, they were at times almost too powerful for the monarchs of Spain. In 1494 or 1495, Ferdinand, the husband of Isabella, who had already assumed the command of the other two orders, prevailed upon Juan de Zuniga, son of the Duke of Arévalo, to resign the grand-mastership of Alcántara. From that time the dignity has remained in the crown of Spain. (A full account of the order has been given by Radez de Andrada in his *Chronicles of Alcántara*, and by Zapater in his *Cister Militante*.)

ALCARGIN, ALCARIN. } [CACODYL.]

ALCARRAZAS. This name is given to vessels made of coarse porous pottery, used in Spain for the purpose of cooling water. The cooling results from the copious evaporation of the small portion of water which soaks through the vessels to the outside; the heat necessary for bringing about this evaporation being drawn from the remaining water in the vessel.

A convenient substitute for the alcarrazas may be made in the following way:—Mix thoroughly, in the dry state, equal parts of siliceous sand and good clay; then bring it to a proper consistence with brine, adding afterwards a considerable quantity of common salt, which must be well incorporated with the clay by beating. Another method is to mix up the clay with twice its weight of charcoal in powder, and bake it until the charcoal is perfectly burnt out. The vessels to be used as coolers must not be fully baked.

For the modes of cooling the wort in making beer and wine, see BREWING; DISTILLING. See also, FREEZING; ICE HOUSES.

ALCHEMY, the pretended art of making gold and silver. The name appears to be derived from the Greek χημεία, chemistry, but the *al* prefixed to it denotes the probability of the Arabic origin of the imposture. Another and subsequent object of alchemy was the preparation of a universal medicine. Those alchemists who were supposed to be skilled in the art, were termed *adepts*, or *the adepts*.

In the opinion of the alchemists, all the metals are compounds, the baser of them containing the same constituents as gold, but mixed with various impurities, which being removed, the common metals were made to assume the properties of gold. The change was effected by what was termed *lapis philosophorum*, or the philosophers' stone, which is commonly mentioned as a red powder possessing a peculiar smell.

It is not quite certain either at what period or in what country alchemy arose; and different opinions on the subject are expressed by authors. Dr. Thomson ('History of Chemistry,' vol. i. p. 14) supposes that it originated among the Arabians when they began to turn their attention to medicine, after the establishment of the Caliphs; or that, if it had been previously cultivated by the Greeks, as there is some reason to suppose, it was taken up by the Arabians and reduced by them into regular form and order. This conclusion is rendered extremely probable, on account of the prefix of the Arabic article *al*.

Hermes Trismegistus is generally mentioned as one of the earliest alchemists; but the writings bearing his name are undoubtedly spurious. In 1692, Dr. Salmon, in his 'Clavis Alchymiæ,' published a translation of the 'Tractatus Aureus' attributed to Hermes, with the works of some other alchemists. The translation is accompanied with notes which rival the original in absurdity. The word *hermetic*, still in common use, is derived from Hermes. Geber, an Arabian physician who lived in the 7th century, is one of the earliest alchemists whose works are extant; but some doubt of their genuineness is entertained. Dr. Thomson ('History,' vol. i. p. 15) remarks, that though the principles which lie at the bottom of alchemy were implicitly adopted by him, he does not attempt to make gold artificially, nor admit the possibility of converting the baser metals into gold. In Dr. Salmon's work, however, the following passage occurs, translated from Geber's 'Alchemy of Sol': "Whatever metal is radically citrine, and brings to equality and cleanses, it makes gold of it; from whence we discern, that copper may be transmuted into gold by artifice," &c. &c.

Geber also treats of the *Medicine, Tincture, Elixir, or Stone of the Philosophers in general.* Dr. Johnson supposes that the word *gibberish*, anciently written *geberish*, was originally applied to the language of Geber and his tribe; many of the quotations given by Salmon would certainly justify the etymology. Although it is also apparent that Geber was an alchemist in the most comprehensive sense of the word, and although his works abound with the most absurd and mystical phrases, yet his chemical labours were directed to the improvement of medicine. He has also described and depicted various furnaces, crucibles, alembics, aludels, and other useful chemical apparatus, of which he was probably the inventor; and he treats of distillation, sublimation, calcination, and various other chemical operations.

Omitting any mention of less celebrated alchemists, we proceed to notice Albert Groot, usually called Albertus Magnus, a German, who was born at Bollstaedt in 1282. He was acquainted with all the sciences usually taught in that age, and his works were published at Leyden in 1651, in twenty-one folio volumes, among which are seven tracts on alchemy. According to Dr. Thomson, Albertus, in his treatise 'De Alchemia,' gives an account of all chemical substances known in his time; was well acquainted with chemical apparatus, and with the methods of purifying the precious metals. He imagined that the metals were composed of mercury and sulphur, and accounts for the diversity of them, by the difference in the proportion of their constituents and their purity. His writings are in general plain and intelligible. Thomas Aquinas is asserted to have been the pupil of Albert; he wrote three works on alchemy which are said to be always obscure, and often unintelligible; the word *amalgam*, signifying a compound of mercury and another metal, occurs, and probably for the first time, in his writings; which contain also some other terms still used in chemistry.

The alchemist next to be mentioned is Raymond Lully, who was born at Majorca in 1235. He was a very singular person; he travelled to various kingdoms to preach Christianity, and died in 1315, on his passage from Africa, where he had been on this service.

Lully is stated to have been the scholar and the friend of Roger Bacon; his reputation as an alchemist was very high, and his works, which are generally obscure, amount to nineteen. He obtained nitric acid by distilling a mixture of nitre and sulphate of iron, observed its power of acting upon metals generally, and of dissolving gold when mixed with sal-ammoniac. He appears also to have known various other chemical compounds, and their action upon each other.

Roger Bacon, frequently called Friar Bacon, a Franciscan monk, was born at Ilchester, in Somersetshire, in 1214. Notwithstanding the great learning and scientific acquirements of Bacon, he was deeply imbued with the mystery of alchemy: this is the more remarkable, because he exposes the absurdity of believing in magic, necromancy, or charms. His chemical and alchemical writings amount to eighteen, a list of which may be seen in Dr. Thomson's 'History of Chemistry,' vol. i. p. 35. Bacon appears to have been acquainted with the composition of gunpowder, and by some he is thought to be the inventor of it. It was, however, probably introduced into Spain by the Moors; and Bacon, from his acquaintance with Arabic, might have acquired information of its composition from some writing in that language. Bacon has hinted at his knowledge of the ingredients of gunpowder, in his 'Epistola de Secretis Operibus Artis et Naturæ et de Nullitate Magiæ,' in the following enigmatical sentence: "Sed tamen salis petræ Luru. Vopo. Vir Can Vtriet sulphuris; et sic facias tonitrum et coruscationem, si scias artificium.' Saltpetre and sulphur being distinctly named, we have only to suppose charcoal to be concealed under the enigmatical terms quoted, and then all the substances contained in gunpowder are mentioned as capable of producing thunder and lightning when properly used.

It is not to be wondered at, in a barbarous age, that one who was skilled in so many sciences should be accused of witchcraft; we accordingly find, that Bacon was imprisoned on this charge, and narrowly escaped starvation, or being burnt as a magician. The real ground of his offence appears to have been his exposure of the immorality of the priesthood. He died either in 1284 or 1285; his 'Opus Majus,' edited by Dr. Jebb in 1733, and the 'Epistola,' already quoted, are the works of this author most worthy of perusal. In the list of Bacon's works already referred to, there are several professedly on alchemy. Dr. Salmon has translated one which is not among them, called 'Radix Mundi;' another work on alchemy, called 'Speculum Alchemiæ,' mentioned in the list above referred to, is also translated by Dr. Salmon.

Arnoldus de Villa Nova was not only an alchemist, but an astrologer and magician. He is said to have been born, in 1240, at Villeneuve, a village of Provence: he was educated at Barcelona, which place he was obliged to leave, in consequence of foretelling the death of Peter of Aragon. When he left Barcelona, he went to Paris, and travelled through Italy; and afterwards taught in the university of Montpelier. He acquired high reputation as a physician; and was well skilled in several languages and in the sciences of his time.

He wrote about twenty different works, some of which are professedly on alchemy: the book entitled 'Rosarium' is probably the most curious, it being intended as a compendium of the alchemy of the day. The second part of this work, which professes to treat of the art of making the philosophers' stone, is stated to be quite unintelligible. Like his predecessors, he considered mercury as a constituent of metals; and professed that he could increase the philosphers' stone at pleasure. He died in the year 1313, on his way to visit Pope Clement V., who lay sick at Avignon.

Raymond Lully and Arnoldus de Villa Nova are stated to have inspired men of all ranks with a taste for alchemy. Pope John XXII. was one of them; he professed and described the art of transmuting metals; and boasts, in the beginning of his book, that he had made 200 ingots of gold, each weighing a hundred pounds.

The 14th century produced a considerable number of alchemists,—as Nicolas Flammel, Pierre le Bon of Lombardy, the monk Ferrari in Italy, Cremer, abbot of Westminster, the disciple and friend of Lully, John Daustein and Richard, in England, practised and wrote upon hermetic philosophy. The work attributed to Flammel is generally reckoned spurious. The 15th century was more productive in adepts, even than the preceding. About 1408 flourished John Isaac Hollandus, and his countryman of the same name, who were either brothers or a father and son. They were born in the village of Stolk, in Holland. Few circumstances are known respecting them. They wrote several treatises on chemistry, which are remarkable for clearness and precision, considering the time at which they appeared. In the opinion of Boerhaave, they were very distinguished chemists. Paracelsus and, subsequently, Boyle repeated many of the experiments contained in their works; they related, however, principally to the transmutation of metals. In this century was born George Ripley, who was canon of Bridlington, in Yorkshire: he published a work, called 'Medulla Alchymiæ,' which is translated by Dr. Salmon, in his 'Clavis.' This work is replete with the same sort of unintelligible jargon which usually abounds in such productions. He wrote another work, in rugged rhyme, called the 'Compound of Alchemie,' which was dedicated to Edward the Fourth.

Basil Valentine, a Benedictine monk, of Erfurt, in Germany, was born at the latter end of the 14th century; and, with the exception of Paracelsus, he was, perhaps, the most famous professor of the hermetic philosophy: but he possessed, at the same time, very considerable merit as a chemical experimenter, and was much occupied in the preparation of chemical medicines. He first introduced antimony into medicine: his work on this subject is entitled 'Triumphwagen Antimonii,' which was translated from the German into Latin, under the title of 'Currus Triumphalis Antimonii,' by Kerkringius, in 1671. In this book he strongly advocates the chemical sect; and treats the practice and theories of his opponents with great severity, because they are unable to prepare their own medicines: "They know not whether they be hot or dry, black or white; they only know them as written in their books, and seek after nothing but money. Labour is tedious to them, and they commit all to chance; they have no consciences, and coals are outlandish wares with them; they write long scrolls of prescriptions, and the apothecary thumps their medicine in his mortar, and health out of the patient."

Basil Valentine was of opinion that the metals are compounds of salt, sulphur, and mercury, and that the philosophers' stone was composed of the same ingredients. He was acquainted with many of the properties of several metals, and with the effects they were capable of producing by their chemical agency. He was, however, more particularly informed with respect to antimony, and knew most of the preparations of it which at present exist in the pharmacopœias of Europe. Twenty-three different publications have been ascribed to Basil Valentine, but it is uncertain how many of them were written by him. His works contain the first accurate mention of the nitric, hydrochloric, and sulphuric acids, with intelligible directions for preparing them; and he was acquainted with a very considerable number of metallic salts and compounds.

We have now mentioned the principal writers on alchemy. There arose, however, from time to time, various authors, who appear to have been rather believers in the possibility of the transmutation of metals than pretenders to have accomplished it. A list of alchemists, from Hermes, who is represented as having flourished nearly 2000 years before the Christian era, down to Mathieu Dammy, in 1739, may be seen in the 'Encyclopédie Méthodique:' it is copied from Dufrenoy's 'Histoire de la Philosophie Hermétique.' This list contains names which are more familiar as chemists than as adepts; such, for example, as Paracelsus (who applied the philosophers' stone, not to the making of gold, but to the preparing of medicines), Libavius, Van Helmont, Glauber, and Kunckel.

To these believers in the art may be added Bergmann, a celebrated chemist of very late date, who, after summing up the evidence for and against the possibility and probability of transmutation, observes, respecting the numerous relations that have been given by writers of apparent veracity, that, "although most of them are deceptive, and many uncertain, some bear such character and testimony, that, unless we reject all historical evidence, we must allow them entitled to confidence."

The later Peter Woulfe, who was a Fellow of the Royal Society, and died in 1805, is reported to have been a believer in alchemy. His name is associated with chemical operations on account of the apparatus which bears his name, but which had been previously described by Glauber.

The last person, at least in this country, who professed to convert mercury into silver and gold, was Dr. Price of Guildford: he is said to have convinced some persons of the possibility of the transmutation; his experiments were to have been repeated before competent judges, but he prevented detection and exposure by destroying himself with laurel water. This happened in 1782.

For an account of that mysterious substance, the philosophers' stone, by which the wonders of transmutation were worked, and a detail of the process for preparing it, given in the words of an adept, we refer the reader to Dr. Thomson's 'History of Alchemy,' p. 23.

Dr. Thomson states, that the philosophers' stone, prepared by the elaborate process above referred to, could hardly have been anything else than an *amalgam of gold;* and "there is no doubt," he adds, "that amalgam of gold, if projected into melted lead or tin, and afterwards cupellated, would leave a portion of gold; all the gold, of course, that existed previously in the amalgam. It might, therefore, have been employed by impostors to persuade the ignorant that it was really the philosophers' stone; but the alchemists who prepared the amalgam, could not be ignorant that it contained gold."

In the 'Memoirs of the Academy of Sciences' for 1772, M. Geoffroy published an account of the various modes in which the frauds of the adepts were carried on; some of these we shall mention. He observes that, instead of the mineral substances which they pretended to transmute, they put oxide (*chaux*) of gold or silver at the bottom of the crucible, the mixture being covered with some powdered crucible and gum-water, or wax, so that it might look like the bottom of the crucible. On other occasions, they made a hole in a piece of charcoal, filled it with powdered gold or silver, and closed the hole with wax; or they soaked charcoal in a solution of these metals, and threw the charcoal, when powdered, upon the material to be transmuted. They used also small pieces of wood, hollowed at the end, put filings of gold or silver into the cavity, and stopped it with fine sawdust of the same wood, which on burning left the metal in the crucible. Sometimes they whitened gold with mercury, and made it pass for silver or tin; and the gold, when melted, was exhibited as gold obtained by transmutation. They had a solution of nitrate of silver, or of chloride of gold, or an amalgam of gold or silver, which, being adroitly introduced into the crucible, furnished the necessary quantity of metal. A common exhibition was, to dip nails into a liquid, and to take them out apparently half converted into gold: these nails consisted of one-half iron, neatly soldered to the other half, which was gold, and covered with something to conceal the colour, which the liquor removed. Sometimes they had metals made of gold and silver soldered together; the gold side was whitened with mercury, dipped into some transmuting liquid, and then heated; the mercury being dissipated, the gold portion of the metal appeared.

Bergmann, in his 'Essays,' vol. iii. p. 93 ('History of Chemistry during the Middle Ages'), has given a number of cases in which gold had been supposed to be formed by the use of the philosophers' stone. They were unquestionably the results of some of the above-mentioned tricks; but Bergmann states it as his opinion, that some accounts of transmutation are "entitled to a greater degree of credit" than others. "For doubtless," he adds, "if a person, who has no faith in the changes of alchemistry, should obtain by chance a small piece of the philosophers' stone, and, on making the experiment alone in his closet, procure a quantity of gold heavier than the stone, will it not be difficult to explain in what manner he was liable to be deceived?" Before the difficulty is required to be explained, the fact must be placed on incontestable evidence.

The question has sometimes been asked, whether the labours of the adepts have been favourable or otherwise to the progress of chemical science? This question we should be inclined to answer in the negative, on account of the disrepute into which the jargon of their writings and the frauds of their experiments must have brought, not only their authors, but the science which they abused. On this subject Dr. Thomson however remarks ('History,' p. 30), "As the alchymists were assiduous workmen, as they mixed all the metals, salts, &c., with which they were acquainted, in various ways with each other, and subjected such mixtures to the action of heat in close vessels, their labours were occasionally repaid by the discovery of new substances, possessed of much greater activity than any with which they were previously acquainted. In this way they were led to the discovery of sulphuric, nitric, and hydrochloric acids. These, when known, were made to act upon the metals; solutions of the metals were obtained, and this gradually led to the knowledge of various metalline salts and preparations, which were introduced with considerable advantage into medicine. Thus the alchemists, by their absurd pursuits, gradually formed a collection of facts, which led ultimately to the establishment of scientific chemistry." It may be also stated in favour of the alchemists, that phosphorus was discovered by an adept of the name of Brandt, at Hamburg, in 1677: this he procured from urine, while searching for some substance capable of transmuting silver into gold.

Gibbon, 'Decline and Fall,' vol. ii. p. 137, speaking of alchemy, says, that, "congenial to the avarice of the human heart, it was studied in China as in Europe, with equal eagerness, and with equal success. The darkness of the middle ages insured a favourable reception to every tale of wonder; and the revival of learning gave new vigour to hope, and suggested more specious arts of deception. Philosophy, with the aid of experience, has at length banished the study of alchemy; and the present age, however desirous of riches, is content to seek them by the humbler means of commerce and industry."

A not very successful attempt has lately been made to show that the alchemists were in reality moral philosophers, who clothed their thoughts in metaphorical language, and that the transformations they describe refer to mental and not to chemical processes.

ALCOHOL. ($C_4H_6O_2$)—*Spirit of Wine; Hydrate of Ethyl; Vinic Alcohol.* Alcohol was first discovered as a distinct compound by a physician of Montpelier about 1300, but its true composition was first made known by De Sassure. Alcohol is derived, 1st, from the fermentation of saccharine matters, and, 2nd, from the products of the destructive distillation of coal and other organic substances. It may also be made artificially from its elements. Practically it is always obtained from the first source. By contact with yeast, grape sugar is transformed into alcohol and carbonic acid.

$$\underbrace{C_{12}H_{12}O_{12}}_{\text{Grape Sugar.}} = \underbrace{2C_4H_6O_2}_{\text{Alcohol.}} + \underbrace{4CO_2.}_{\text{Carbonic Acid.}}$$

The alcohol thus produced is contained in the various fermented liquors, such as beer, wine, wash, &c., greatly diluted with water and mixed also with several other substances. From the latter it is freed by repeated distillation, by which much of the water is also got rid of; but on account of the chemical affinity existing between alcohol and water, it is not possible to obtain the former free from the latter by simple distillation, though frequently repeated; the specific gravity of the product is never less than 0·825, and the rectified spirit of wine of commerce and of the 'London Pharmacopœia' has a specific gravity of 0·835.

In order to obtain pure or absolute alcohol, other methods must be resorted to. According to M. Sœmmering, the water may be entirely separated from alcohol by the following process: Put the spirit into an ox's bladder coated with isinglass, and expose it to a temperature of 105° to 120°; the interior of the bladder is moistened by the water of the spirit, and whilst the exterior coat dries, fresh portions of water continue to penetrate the bladder, and to evaporate from its surface, while but little of the alcohol escapes with it. Spirit put into a wide-mouthed bottle and tied over with bladder, suffers a similar evaporation of the water and concentration of the alcohol. Geiger and Planiava assert, however, that the remaining alcohol still retains three per cent. of water. Pajot Descharmes proposed to place spirit in a flat vessel beside fragments of chloride of calcium under a closed receiver; the air contained in this soon becomes loaded with the vapour rising from the spirituous liquor, the salt combines with the aqueous portion of it, and the alcohol is gradually concentrated; some, however, is lost, being vaporised and condensed with the water. Berzelius, 'Traité de Chimie,' t. vi. 448.

Graham proposes a process upon a similar principle, namely, that of placing a shallow vessel of spirit over another containing coarsely powdered lime, under a bell-glass, upon the plate of an air-pump; the air is exhausted till the alcohol begins to boil, and the lime absorbs the water only of the vapour which rises. If sulphuric acid be substituted for lime, then both the water and spirit evaporate and are totally absorbed. 'Edinb. Phil. Trans.' 1828.

Although these are interesting processes, yet they are scarcely applicable on an extensive scale. The best methods depend upon adding to the spirit some substance which has affinity for the water, and none or but little for the alcohol; thus carbonate of potash is a deliquescent salt, and has consequently a great affinity for water, but unlike most salts of this description, it has no affinity for alcohol, and is totally insoluble in it. When, then, dry carbonate of potash in powder is put into rectified spirit of wine of specific gravity 0·835, the water which it contains dissolves the alkaline salt, and forms a dense solution, on which the alcohol floats, not, however, quite free from water, for when separated and distilled, its specific gravity is reduced only to 0·815, and therefore it still continues to retain about 5 per cent. of water.

A convenient material for obtaining alcohol, nearly if not quite free from water, is sulphate of copper, strongly dried so as to expel its water of crystallisation. If strong spirit of wine be digested for three or four days with an equal weight of the dried sulphate, and the mixture be distilled from a water bath, alcohol, absolute or nearly so, will pass into the receiver. By repeated rectifications from large quantities of quick lime, alcohol may be obtained perfectly absolute. Chloride of calcium which has been fused so as to render it free from water, is an extremely deliquescent salt, and is more powerful than most substances in separating water from alcohol. Mix equal weights of spirit and pieces of the fused chloride in a stopped bottle; when the salt is dissolved, pour off the clear solution into a distilling apparatus, and continue the operation until the product is equal to half the bulk of the spirit employed. If the distillation be properly conducted, the alcohol obtained is perfectly free from water.

In performing any of these processes, however, it must be borne in mind, that absolute alcohol absorbs water with great avidity, and consequently it can neither be obtained nor preserved absolute, unless it be carefully protected from the air so as to prevent its absorbing atmospheric moisture.

Pure alcohol possesses the following properties: It is a limpid colourless liquid, of an agreeable smell and a hot pungent taste. Its specific gravity is 0·791 at 68°, or 0·7947 at 59°. It has never been frozen, although exposed to a cold of —220°. It is extremely volatile, producing considerable cold during evaporation. Heat expands alcohol in a greater degree than it does water; for 100,000 volumes become 104,168 by being heated from 32° to 100°; whereas an equal bulk of water heated to the same degree, is increased only to 100,908. Under the average atmospheric pressure alcohol boils at about 173°, but in the vacuum of the air-pump, ebullition occurs at 60°, and even below it. In becoming vapour, alcohol absorbs only 0·436 of the heat required to evaporate an equal weight of water; and, according to Gay-Lussac, ('Ann. de Chim. et de Phys.' xv.) the density of the vapour of anhydrous (waterless) alcohol compared with that of atmospheric air, is as 1·613 to 1·000. When the vapour of alcohol is strongly heated, as by being passed through a red hot porcelain tube, it is decomposed, and there are obtained, gaseous hydrocarbons, aldehyde, naphthaline, benzole, phenylic alcohol, and several other substances, together with a small amount of carbon. Alcohol, and the vapour arising from it, are extremely inflammable; it burns with a lambent flame. Although the flame of alcohol yields but little light, its heat is intense; it burns without any smoke, and the only products of the combustion, under common circumstances, are water and carbonic acid. When, however, alcohol is burned in the lamp without flame, in the wick of which a platinum wire is kept ignited, then acetic acid and other products are also formed. There are several substances which communicate colour to the flame of alcohol: boracic acid and cupreous salts impart green; barytic salts, yellow; and the salts of strontia, an intense and beautiful crimson colour.

Alcohol may be fired by the electric spark, which when passed through a mixture of the vapour of alcohol and oxygen gas, causes it to take fire and explode violently. The vapour of alcohol requires three times its volume of oxygen gas to be perfectly burned, and it then yields water and twice its volume of carbonic acid gas. At low temperatures, alcohol suffers but little change by exposure to the air; the portion which does not evaporate is rendered weaker by attracting water, and it absorbs at the same time some air.

Alcohol has great affinity for, and readily mixes with water in all proportions, and during their combination heat is evolved; if, for example, equal measures of water and of alcohol of specific gravity 0·825, both at 50°, be suddenly mixed, the temperature is raised to 70°, and the specific gravity of the mixture, when cooled, exceeds its calculated density; if, however, the alcohol be weak, then the mean density is diminished.

For the density of various mixtures of alcohol and water, see ALCOHOLOMETRY.

In contact with acids, alcohol forms a vast number of ethereal salts, several of which are remarkable for possessing the fragrant odour of various fruits. With concentrated sulphuric acid it yields sulphovinic acid, which, on being heated, produces ether. [ETHER.] Oxidising agents convert it into aldehyde and acetic acid. Chromic acid acts upon it so violently as to cause inflammation when strong alcohol is dropped upon the acid. Pure alcohol does not oxidise when exposed to the air, but when mixed with fermentisable matters it gradually absorbs oxygen, and is converted into acetic acid. Chlorine acts readily upon alcohol, forming a series of chlorinated products, and finally chloral.

The solvent power of alcohol is great; and it has been long known and extensively applied. Graham ('Trans. Royal Soc. Edin.') has shown that, like water, it combines with bodies in definite proportions; these compounds he terms *alcoates*; not many of them have been formed, and they were obtained simply by dissolving the salts constituting their base, and previously rendered anhydrous, in absolute alcohol, with the assistance of heat. On cooling, the alcoates were deposited in the solid state; the crystallisation was generally confused, but in some cases regular forms appeared. The crystals are transparent, soft, and easily fusible by heat in their alcohol of crystallisation; their formation is prevented by the presence of a small quantity of water. Chloride of calcium forms an alcoate consisting of 2 atoms of alcohol and 1 of the salt; nitrate of magnesia, 1 atom salt + 3 atoms alcohol; alcoate of nitrate of lime consists of 2 atoms salt and 5 atoms alcohol. Several metallic salts were also converted into alcoates, and analysed by Graham; the alcohol of some alcoates is retained with so great force of affinity as not to be expelled at a temperature of 400° to 500°.

Alcohol is capable of dissolving the resins, and many similar bodies upon which water has no action; hence its use in varnish-making. With the fixed oils, except castor oil, it does not readily unite; but it dissolves the essential oils and camphor with great facility, and hence its use in pharmacy and perfumery. Some substances which are soluble in water are precipitated from it by alcohol—gum, for example; while, on the other hand, water precipitates resinous bodies from solution in alcohol. Alcohol dissolves sulphur and phosphorus, but not the earths or their carbonates: it also dissolves sugar, soap, the oxalic, tartaric, gallic, benzoic, and some other acids. Alcohol is largely used in the preparation of various kinds of ether. The results of its action with sulphuric acid are very different according to circumstances: thus, by varying the proportions, we may procure sulphovinic acid, ether, oil of wine, or olefiant gas. As it remains fluid at the lowest temperatures, it is advantageously employed in filling thermometer tubes, for experiments on artificial cold; its antiseptic properties are great, and hence its use in preserving anatomical preparations; on account of its ready inflammability, the purity and the intense heat of its flame, it is conveniently, but not economically, employed in chemical lamps, usually termed *spirit lamps*.

It readily dissolves ammoniacal gas; and as the caustic alkalies, potash and soda, are taken up in large quantity by alcohol, and as it does not dissolve their usual impurities, the solution, by dilution with water and subsequent distillation, yields these alkalies in a state of great purity. In analytical operations it is sometimes employed to separate two salts, both of which are soluble in water, but only one in alcohol. It is also largely employed in proximate organic analysis, and in the preparation of the various ethyl compounds used in chemical investigations.

For most of these purposes pure alcohol may be replaced by the *methylated spirit* now allowed by the Excise under certain restrictions to be sold free of duty.

Alcohol, Medical properties of. These are of a twofold kind; first, those in which it is employed on account of its solvent powers, it being, next to water, the most extensively employed solvent, to obtain, preserve, or facilitate the administration of a variety of active principles, vegetable, mineral, or animal; and secondly, those in which its own powers over the human frame lead to its use as a therapeutic agent. The former will be treated of under TINCTURES; and it is only necessary to observe here, that, besides for these, it is employed in many pharmaceutical processes in which it does not ultimately appear, either for its solvent or precipitating properties, such as in the preparation of many of the alkaloids, namely, aconitina, strychnia, &c., which, though the most potent medicinal agents we possess, are greatly restricted in their application by the high price charged for them. This arises partly from the minute quantity in which they exist in their original sources, the plants which produce them; but far more from the high duty on alcohol, which places our practical chemists at a great disadvantage compared with those of France and Germany. Methylated spirit is now allowed to be used, which is a great boon.

The therapeutic properties of alcohol are therefore the only properties to be noticed here; and it is by no means intended to discuss points which have excited keen controversies in reference to the employment of alcoholic stimulants as ordinary beverages, but simply that employment of them which is conceded to be allowable by all parties—their use as medicinal agents. Besides, as many who do not require them are, in accordance with the usages of society, in the habit of taking them, it is proper to indicate which are the least hurtful. The excessive use of ardent spirits is deservedly reprobated, and every reasoning person will gladly lend his aid to root out this almost national vice; the evil effects of which are not limited to the individual, as the physical ailments engendered by habitual drinking have a great tendency to become hereditary. The mental powers of the offspring are also greatly influenced by the habits of the parent; and diseases of the brain, with derangement of the intellectual faculties, are the consequence. The extension of education and the better tone of feeling in the higher classes have done something to banish inebriety from the upper circles of society; and a more correct understanding of what is for their true interests has abated it among the labouring classes. Furnishing the operatives with the means of rational and healthful recreation, both mental and bodily, after the hours of toil, will aid this fortunate revolution. The refreshment of a bath will be found greater, more lasting, and more economical for the workman, than any artificial stimulant, and has been advocated by themselves.

It is proper however that the mode of action of alcohol should be understood, to determine when it should be used. A single moderate dose, suitable for the individual, produces effects which are entirely limited to the viscera of the abdomen. They extend themselves from the solar plexus of nerves to the organs upon which the splanchnic nerve is distributed, and excite in these a livelier action. A feeling of comfort in the abdomen, quicker and more powerful digestion, stronger peristaltic motions, increased desire for meat and drink, more abundant secretion, especially augmented secretion from the kidneys, are the common phenomena which result from the lowest degree of its action. A larger quantity, or several small doses repeated at short intervals, extend the action beyond the sphere of the splanchnic nerve, even to the spinal chord, the brain, and entire nervous system. The feeling of comfort and warmth experienced in the præcordial region is diffused over the whole frame. The pulse is raised, becomes more powerful and quicker, all muscular actions take place with more ease, strength, and capacity of endurance, the tone of the nervous system is raised, the influence of the nervous energy upon the other organs is quicker and more powerful; but, above all, that part of the nervous system whose functions are executed by the brain is most perceptibly increased, as is seen in the greater cheerfulness, humour, and courage, as well as the more active and acute power of thinking. During this degree of action the sensibility to external impressions is unimpaired, or even in many instances augmented, as is manifested by a more eager participation in the incidents occurring or sentiments expressed, and in the expansion of the affections or passions.

Contemporaneously with these, all the functions of organic life are carried on more actively; of which we have proof in the increased secretions, especially of the cutaneous transpiration and secretion of urine.

From this view, it is obvious that alcohol is an agent which, within certain limits, may be most beneficially employed when some portion of the system, particularly the stomach, brain, or kidneys, requires assistance. Hence, under the influence of many sedative poisons, alcohol furnishes the readiest and most potent means of counteracting their effects, the prolonged action of which would prove fatal. Some poisons however, particularly those of ranunculaceous plants, such as monkshood, probably from their active principle being dissolved by the spirit, have their deleterious influence increased by alcohol. In the sinking stage of fevers, and many analogous states, alcohol furnishes the only means of warding off death. In malarious districts and in very humid regions, a moderate use of alcoholic drinks protects the frame against injurious impressions. Hence, in Holland, and even in fenny districts of our own country, alcohol is useful. When cold is conjoined to humidity, it is still more serviceable. The Swiss peasant at great elevations on the Alps, and the shepherd in the Highlands, set the mists of their mountains at defiance; the former by his 'enziangeist,' or 'bitter-snaps,' the latter with whiskey. Such persons are rarely intoxicated. Many persons with feeble and slow digestion have the process expedited by a small portion of alcohol taken after their meals. Those also who suffer much from acidity in the stomach, or who are prone to calculous disorders, find great benefit from pure alcohol, in preference to either malt liquors or wines. (Prout, 'On Diseases of the Stomach,' 3rd ed. p. 9.) For the difference between pure alcohol and alcohol combined with other principles in wines, see WINES. With persons very prone to acidity, pure alcohol agrees better than any wines, especially than the sweet wines; and those disposed to the lithic acid diathesis find alcohol preferable to all wines except those of the Rhine, the employment of which however must be habitual, not occasional. Immense benefits would be conferred on the community in this country, if those light wines could be introduced at a moderate price, as the quantity of alcohol in them is very small compared with other wines.

A reference to the chemical composition of alcohol will show that it is a highly carbonised compound. When taken to excess it produces exhaustion of the nervous power and an oppression of the circulation, almost apoplectic. Emetics or the stomach-pump, vegetable acids given freely, occasionally dashing cold water on the face or head, artificial respiration, and very cautious venesection, in some instances restore the sufferer. Liebig says alcohol has not been detected in the urine. When the quantity taken is not excessive, and can be all exhaled by the lungs, this may be true; but the presence of alcohol in the brain, blood, and urine has been proved by Dr. Percy.

(Dr. Golding Bird, in *Medical Gazette*, vol. xxxiv. p. 690.)

ALCOHOLIC DRINKS. The number of alcoholic drinks is surprisingly large and varied. The following are the principal:—*Agua Ardiente*, made in Mexico, from the fermented juice of the Agave; *Arack* or *Arrack*, made in India from the juice of the palm and from rice; *Araka*, made in Tartary, from fermented mare's milk; *Araki*, made in Egypt from dates; *Arika*, made in Tartary and in Iceland, from fermented cow's milk; *Brandy*, made in nearly all wine countries from wine and from fruits; *Branntwein*, the coarsest sort of spirit used in Germany, is manufactured principally from potatoes, but occasionally rye is used; *Geneva* or *Hollands*, made in Holland from malted barley or rye, rectified on juniper berries; *Gin*, made in England from malted barley, rye, or potatoes, and rectified with turpentine; *Goldwasser*, made at Dantzic from various kinds of corn, and rectified with spices; *Kirschwasser*, made in Switzerland and Germany from the Machaleb cherry; *Lau*, made at Siam from rice; *Maraschino*, made in Dalmatia from the Macarska cherry; *Mahwah Arrack*, made in India from the flowers of the Madhuca tree; *Rum*, made in the West Indies and South America from cane sugar, and molasses; *Rakia*, made in Dalmatia from the husks of grapes, mixed with aromatics; *Rossolio*, made at Dantzic from a compound of brandy with certain plants; *Sekis-Kayarodka*, made at Scio from fruit and lees of wine; *Slatkaia-trava*, made at Kamschatka from a sweet grass; *Show-choo*, made in China from the lees of rice wine; *Trosta*, made in the Rhenish provinces from the husks of grapes fermented with barley and rye; *Tuba*, made in the Philippine Islands from palm-wine; *Vino Mercel*, made in Mexico by distilling the fermented juice of the Agave; *Whiskey*, made in Scotland and Ireland from raw and malted grain, and in the south of France from sloes.

However different the above alcoholic beverages may be, they all have a common resemblance in these particulars:—they all consist chiefly of spirit or alcohol diluted in very various proportions; they all contain portions of essential oils, or colouring matter, or extractive matter; they all derive their distinctive character from the nature of these added substances; and they may all be made to yield pure alcohol by re-distillation and rectification. [BRANDY; DISTILLATION; GIN; &c.]

Numerous as they are, these drinks are wholly distinct from the various rich and luscious CORDIALS and LIQUEURS. The Americans display remarkable ingenuity in the preparation of such drinks, and no less in the invention of extraordinary names for them.

ALCOHOLOMETRY. The process of estimating the percentage amount of absolute alcohol in any sample of spirits, which is usually effected by the determination of the specific gravity of the sample. As a preliminary to this estimation, it is necessary that the alcohol should be freed as far as possible from every foreign ingredient except water. This is easily effected, in the case of wines and fermented liquors, by submitting them to distillation until the whole of the alcohol has passed over. The temperature of the distillate being then brought to 60°, it is ready for the determination of the specific gravity, which is performed by a delicate hydrometer. [HYDROMETER.] Vast numbers of experiments have been made by various observers on the densities of mixtures of alcohol and water, and the results of these experiments form the groundwork of the different tables exhibiting the percentage of alcohol in spirits of various specific gravities. The following table by Drinkwater is one frequently used in alcoholometry:—

Specific gravity at 60° F.	Percentage by weight of alcohol.	Specific gravity at 60° F.	Percentage by weight of alcohol.	Specific gravity at 60° F.	Percentage by weight of alcohol.

In order to avoid the trouble of reducing the temperature of the sample of spirits to 60°, tables of a more elaborate nature have been constructed, showing the percentage of alcohol from the density taken at any temperature within the ordinary range of our climate; but these tables are too voluminous for insertion here.

In this country it is usual to express the strength of spirits in degrees *under* or *over proof*; the strength of proof spirit being fixed by Act of Parliament at such a specific gravity that at 51° F. thirteen volumes are equal in weight to twelve volumes of water. Proof spirit has therefore, according to this standard, a density of ·9186 at 60°, and contains very nearly half its weight of absolute alcohol (49·5 per cent.). Sykes' hydrometer is the instrument in general use by the Excise for estimating the strength of spirits according to this standard, and its scale is so arranged as to show the volume of water which must be added to or abstracted from 100 volumes of the spirit in order to bring it to the *proof* standard. Thus if the hydrometer indicates 18 over proof, it shows that 18 volumes of water must be added to 100 volumes of the spirit to reduce it to proof strength; whilst 24 under proof signifies that 24 volumes of water must be abstracted from 100 volumes of spirit to render it proof; or in levying the duty upon such spirit, 100 gallons must be reckoned only as 76 gallons, the duty being assessed upon the proof gallon.

An ingenious method of estimating the alcohol in fermented liquors, without the trouble of previous distillation, has been devised by M. Tabarié ('Ann. de Chim. et de Phys.' xlv. 222). It consists in boiling a known volume of the liquor, the density of which has been estimated, until the whole of the alcohol has been expelled; then replacing the liquid evaporated by an equal volume of distilled water, and again taking the specific gravity, which will now be found to be higher. A table prepared for the purpose shows the percentage of alcohol from this difference in density. Another and more accurate method of effecting the same object consists in ascertaining the boiling point of the liquor. Water boils at 212° and alcohol at 173°, when the barometer stands at 30 inches; consequently a mixture of the two will boil at some temperature between these points, dependent upon the relative quantities of alcohol and water present. Tables of the boiling points of spirits of different but known strengths having been constructed, a reference to these shows at a glance the percentage of alcohol in any sample the boiling point of which has been ascertained. It is found that this method yields results sufficiently accurate with most of the fermented liquors and sweetened spirits in ordinary use, as the sugar and salts present affect the boiling point to a scarcely sensible degree.

The following table embodies the results of alcoholometrical experiments by Brande, Christison, and others, on the percentage of alcohol in the chief descriptions of wine, beer, and spirits:—

		Percentage of absolute alcohol.
Strong Port		17·10
Strong Port, mean of seven samples		16·20
White Port		14·97
Dry Lisbon		16·14
Madeira	from	14·09 to 16·90
Sherry	from	13·98 to 16·17
Teneriffe		13·64
Shiraz		12·95
Malmsey		12·86
Amontillado		12·63
Claret	from	7·72 to 8·99
Rivesaltes		9·31
Hambacher		7·35
Rudesheimer	from	6·90 to 8·40
Tokay		9·09
Champagne		11·60
Cognac		53·39
Rum		53·68
Geneva		51·60
Whiskey		54·32
Edinburgh Ale	from	5·70 to 6·06
Burton Ale		8·88
Stout		6·80
Best London Porter		5·36
Bavarian Beer	from	3·60 to 4·20

ALCOHOLS. Under this term chemists now understand a series of bodies which may be represented as water in which one-half of the hydrogen is replaced by a positive organic radical, thus:—

$$\left.\begin{matrix}H\\H\end{matrix}\right\}O_2. \qquad \left.\begin{matrix}CnH(n+1)\\H\end{matrix}\right\}O_2.$$

Water. Alcohol.

CnH (n+1) being the general formula of a series of uniatomic positive radicals, *n* here representing an even number of atoms, as 2, 4, 6, &c. [CHEMICAL FORMULA]. The above is the general formula of the most important and best-investigated series of alcohols, of which the common or vinic alcohol $\left(\left.\begin{matrix}C_4H_5\\H\end{matrix}\right\}O_2\right)$ is a member. The following are the chief alcohols belonging to this series:—

ALCOHOLS.

Methylic.	Butylic.	Cetylic.
Ethylic, or Vinic.	Amylic.	Cerylic.
Propylic.	Caproylic.	Melissic.
	Caprylic.	

The two first have been long known; the others have been discovered by the more recent researches of Cahours, Brodie, Balard, Bouis, Wurtz, and Chancel.

Most of the alcohols are liquid; but the three last in the list are solid, at the ordinary temperature. All, except the higher terms of the series, are capable of being distilled without decomposition. By oxidising agencies they pass first into aldehydes, and finally into acids

$$\underset{\text{Alcohol.}}{\left.\begin{matrix}CnH(n+1)\\H\end{matrix}\right\}O_2} + O_2 = \underset{\text{Aldehyde.}}{\left.\begin{matrix}CnH(n-1)O_2\\H\end{matrix}\right\}} + \left.\begin{matrix}H\\H\end{matrix}\right\}O_2.$$

and

$$\underset{\text{Aldehyde.}}{\left.\begin{matrix}CnH(n-1)O_2\\H\end{matrix}\right\}} + O_2 = \underset{\text{Acid.}}{\left.\begin{matrix}CnH(n-1)O_2\\H\end{matrix}\right\}O_2}.$$

In contact with acids under favourable circumstances they yield a series of bodies possessing generally a fragrant odour, and termed *ethers* or *ethereal salts*. [ETHEREAL SALTS.] Heated with the sulphuric or phosphoric acid several of the alcohols lose water and are converted into ethers. The alcohols are produced by various chemical processes; thus, the methylic, ethylic, and propylic alcohols are derived from the destructive distillation of wood, and of coal; several, as the ethylic, propylic, butylic, amylic, and caproylic are obtained by the fermentation of saccharine liquids; the ethylic and propylic may also be produced by acting with water upon a solution of their olifenes (C_4H_4 and C_6H_6) in concentrated sulphuric acid, whilst the cetylic, cerylic, and melissic are derived from animal secretions.

Another series of alcohols have the general formula $\left.\begin{matrix}CnH(n-1)\\H\end{matrix}\right\}O_2$; it is represented by the allylic alcohol recently discovered by Hofmann and Cahours, which contains the radical allyl (C_6H_5), and has the formula $\left.\begin{matrix}C_6H_5\\H\end{matrix}\right\}O_2$. Allylic alcohol is obtained by treating the oxalate of allyl with ammonia; oxamide is at the same time produced, according to the following reaction:—

$$\underbrace{C_4O_6,\ (C_6H_5O)_2}_{\text{Oxalate of Allyl.}} + 2NH_3 = 2\underbrace{(C_6H_5O,\ HO)}_{\text{Allylic Alcohol.}} + \underbrace{N_2H_4C_4O_4}_{\text{Oxamide.}}$$

Allylic alcohol is a very mobile liquid, insoluble with water in all proportions, and possessing a pungent odour irritating the eyes and lungs. It boils at 217°, and when ignited burns with a luminous flame. By oxidising agents it is converted into acroleine and acrylic acid, to which bodies it stands in the same relation as vinic alcohol to acetic aldehyde and acetic acid. Allylic alcohol yields an ether the oxide of allyl $\left(\begin{matrix}C_6H_5\\C_6H_5\end{matrix}\right\}O_2$, and a series of ethereal compounds; in fact, in its chemical relations, it bears the closest analogy to vinic alcohol.

A third series of alcohols containing the radicals of the formula (Cn H(n — 7)), is represented by phenylic alcohol, or carbolic acid as it is frequently termed, which has the formula $\left.\begin{matrix}C_{12}H_5\\H\end{matrix}\right\}O_2$. [PHENYL SERIES.]

A fourth series, discovered by M. Canizzaro, have the same general formula as the last, but are only isomeric, and not identical or homologous with the third series. The only alcohols at present known belonging to this series are the following:—

Benzoic alcohol $\left.\begin{matrix}C_{14}H_7\\H\end{matrix}\right\}O_2$. Cuminic alcohol $\left.\begin{matrix}C_{14}H_7\\H\end{matrix}\right\}O_2$.

All the alcohols belonging to the four series above described contain *uniatomic* radicals, that is, radicals representing or replacing one atom of hydrogen in a double atom of water; recent researches however have demonstrated the existence of other classes of alcohols, containing *biatomic* and *teratomic* radicals, replacing respectively two and three atoms of hydrogen in as many double atoms of water. Glycol ($C_4H_6O_4$) is an example of a biatomic, and glycerin ($C_6H_8O_6$) one of a teratomic alcohol. The following formulæ exhibit the relations of these three families of alcohols to each other and to water:—

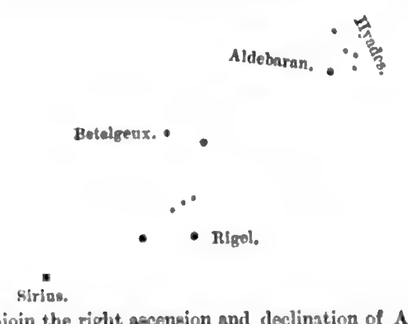
		Water Types.
Vinic alcohol	$\left.\begin{matrix}(C_4H_5)\\H\end{matrix}\right\}O_2$	$\left.\begin{matrix}H\\H\end{matrix}\right\}O_2$.
Glycol . . .	$\left.\begin{matrix}(C_4H_4)''\\H_2\end{matrix}\right\}O_4$	$\left.\begin{matrix}H_2\\H_2\end{matrix}\right\}O_4$.
Glycerin . .	$\left.\begin{matrix}(C_6H_5)'''\\H_3\end{matrix}\right\}O_6$	$\left.\begin{matrix}H_3\\H_3\end{matrix}\right\}O_6$.

ALCORAN, or ALKORAN. [KORAN.]

ALCOVE. This term is found in most of the modern European languages, and is similarly applied throughout to a recess in a room intended for a bed, or in which a bed may be placed. It is not however necessarily restricted to this meaning; and in England, where such recesses are not so common in bed-chambers as they are in some other countries, and particularly in Spain and France, alcove is applied to a similar recess in a room of any kind, and yet more commonly to an ornamental covered garden-seat.

The term is originally from the Arabic language, in which it means, simply, the cave or recess; and it passed into the other European languages through the Spanish, which acquired it during the occupation of a part of Spain by the Arabs.

ALDE'BARAN, the Arabic name of a large and bright star of the first magnitude, called in modern catalogues *α Tauri*, situated in the eye of the constellation Taurus, whence it is called also by the Arabs *Ain al Thaur*, the bull's-eye. It is the bright star in the group of five, known by the name of the HYADES, on which account it is called by Ptolemy, ὁ λαμπρὸς τῶν Ὑάδων. Its light is rather reddish, and of late years it has become remarkable as having been frequently occulted by the moon, and having exhibited the curious phenomenon of projection on the moon's disc. [OCCULTATION.] It is easily found in the heavens by the following directions: If a line be drawn through the three conspicuous stars forming the belt of Orion, *towards the head*, it passes just below Aldebaran and the Hyades; if *towards the feet*, it passes through Sirius, which is about the same distance from the belt as Aldebaran. This is shown in the following diagram:—



We subjoin the right ascension and declination of Aldebaran at the beginning of the years 1800 and 1859. The difference is owing to the precession of the equinoxes, as this star has no perceptible proper motion.

Date.	Right Ascension.	North Declination.

ALDEHYDE. [OTHYL, HYDRIDE OF.]

ALDEHYDE-AMMONIA. [OTHYL, HYDRIDE OF.]

ALDEHYDIC ACID, *Acetous Acid* ($HO, C_4H_3O_3$). An acid compound, supposed to be formed when aldehyde is heated in contact with solutions of the salts of silver. Its existence as a distinct acid is however very questionable.

ALDERMAN. This word is from the Anglo-Saxon *ealdorman* or *eoldorman*. The term *ealdorman* is composed of *ealdor*, originally the comparative degree of the adjective *eald* ('old'), and *man*; but the word *ealdor* was also used as a substantive, and as such was nearly synonymous with the old English term *elder*, so often met with in our version of the Bible. In a philological sense, the terms *ealdor* and *ealdorman* were equivalent; but in political acceptation they differ, the former being more general, and, when used to express a specific degree, commonly denoting one lower than ealdorman. In both terms the notion of some high office, as well as that of rank or dignity, seems to be inherent; but ealdorman, at the same time, expressed a definite degree of hereditary rank or nobility which ealdor does not so necessarily imply. Princes, earls, governors of provinces, and other persons of distinction, were generally termed Aldermen by the Anglo-Saxons. This word was also applied to certain officers in particular; thus, there was an Alderman of all England (*Aldermannus totius Angliæ*), the nature of whose office Spelman says "he cannot divine, unless it corresponded to the office of Chief Justiciary" in later times. There was also a King's Alderman (*Aldermannus Regis*), supposed to have been an occasional judge, with a commission to administer justice in particular districts; it is possible however that his duties may have resembled those exercised by the king's sergeant in the time of Bracton, when there are traces of the existence of an officer so called, appointed for each county, and whose duty it was to prosecute pleas of the crown. Besides these, there were aldermen of cities, boroughs, and castles, and aldermen of hundreds, upon whose particular functions it would now be useless to speculate.

In modern times, aldermen are individuals invested with certain privileges and duties in municipal corporations, either as civil magistrates themselves, or as associates to the chief civil magistrate of such corporations.

In the municipal boroughs of England and Wales, remodelled by 5 & 6 Wm. IV. c. 76, the resident burgesses elect councillors. The councillors hold office for three years, and one-third of their number go out annually. The aldermen are elected by the council from its own number for six years, and one-half go out every three years. One-fourth of the municipal council consists of aldermen and three-fourths of councillors. (Blackst. Comm., Mr. Kerr's ed. vol. i. pp. 523, 525.)

In the corporation of London, which is not affected by the 5 & 6 Wm. IV. c. 76, the Court of Aldermen consists of 26 aldermen, including the lord mayor: 25 are elected for life by such freemen as are householders of the 25 wards; the 26th alderman, who belongs to the dependency of Southwark or Bridge-Without, is not elected at all, but when the office is vacant the other aldermen have in seniority the option of taking it. The alderman who does take it holds it for life, and thereby creates a vacancy as to the ward for which he formerly sat. The Court of Aldermen possess the privilege of rejecting, without reason assigned, any person chosen for alderman by the electors, and, after three such rejections, of appointing to the vacancy. The lord mayor is appointed from such of the aldermen as have served the office of sheriff. The aldermen are the magistrates for the city of London, and judges *ex officio* of the Central Criminal Court. They possess various kinds of authority, both of a judicial and legislative nature, in the affairs of the corporation.

ALE. The difference between ale and beer is not very distinctly marked. In London, ale is generally a more costly beverage than beer; whereas in country districts the name of beer is often reserved for the better and stronger kinds of malt liquor. In mild or new ale, there is generally a larger amount of saccharine matter and mucilage than in beer, porter, or stout; but in old ale the fermentation has been carried to a greater extent, and the sweetness nearly or wholly disappears. The differences observable in ale depend upon the proportion between the malt and hops, the degree to which the malting has been carried, the quality of the water employed, the heat of the water in mashing, the temperature at which the fermentation is conducted, and the extent to which that process is carried. Nearly every county has its own peculiar ale, known from others by qualities depending on one or more of the above circumstances; but the mode of preparing the malt seems to have a greater influence than anything else on the quality obtained.

Mr. Cooley, in his 'Cyclopædia of Practical Receipts,' describes the operations for producing those kinds of ale known by the names of Barnstaple, Bavarian, Burton, Dorchester, Edinburgh, Essex, London, Nottingham, Welsh, Windsor, and Yorkshire ales; with the proportions of ingredients employed, and the kinds of malt and hops selected.

Circumstances have recently attracted attention to the quality of Burton ale; and the brewers of that town, in answer to the statements and queries on the subject, have unanimously asserted that no substances whatever are used in the production of that celebrated beverage except malt, hops, and water; the goodness of the materials and the skilful conduct of the processes being the only 'secrets' in the matter. Towards the close of 1858 there was commenced, at Burton-on-Trent, the construction of one of the largest breweries in England, solely for the brewing of 'Pale Ale,' by Messrs. Allsop; and the establishment belonging to the same firm, near the Minories, illustrates the admirable way in which railways are now rendered available for the warehousing of manufactured produce.

As the mode of producing ale differs little from that adopted for beer, it will suffice to refer to BREWING.

ALE-CONNER. An ale-conner is an ale-kenner, one who kens or knows what good ale is. The office of ale-taster or ale-conner is one of great antiquity. Those who held it were called 'gustatores cervisiæ.' Ale-conners or ale-tasters were regularly chosen every year in the court-leet of each manor, and were sworn to examine and assay the beer and ale, and to take care that they were good and wholesome, and sold at proper prices according to the assize; and also to present all default of brewers to the next court-leet. Similar officers were also appointed in boroughs and towns corporate; and in many places, in compliance with charters or ancient custom, ale-tasters are, at the present day, annually chosen and sworn, though the duties of the office are fallen into disuse. In the manor of Tottenham, and in many others, it was the duty of the ale-conner to prevent unwholesome or adulterated provisions being offered for sale, and to see that false balances were not used. In 4 Jac. I. c. 5, which was intended for the prevention of drunkenness, the officers more especially charged with presenting offences against the Act were constables, churchwardens, head-boroughs, tithing-men, ale-conners, and sidesmen. In most places an inspector of weights and measures now performs the duties formerly exercised by the ale-conner.

The duty of the ale-conners appointed by the corporation of the city of London, is to ascertain that the beer sold in the city is wholesome, and that the measures in which it is given are fair. For this purpose they may enter into the houses of all victuallers and sellers of beer within the city. The investigation is made four times in the year; and on each occasion it occupies about fourteen days. The days are not publicly known beforehand. Southwark is not visited. The investigation into the wholesomeness of the article has fallen into disuse. Fairness in the measures is insured by requiring all pots to be stamped with the city arms, and the ale-conners report to the aldermen such houses as do not comply with the rule, and such as have pots with forged stamps. In the municipal boroughs of England and Wales, to which the inquiries of the Commissioners of Corporation Inquiry extended in 1837 (234 in number), there were in 25 boroughs officers called 'ale-tasters;' in 6 they were termed 'ale-founders;' and in 4, 'ale-conners.'

The ancient regulations which the ale-conners were appointed to carry into effect appear to have been dictated by a regard to public health; but in modern times, when ale and beer had become exciseable commodities, the restrictions and provisions introduced from time to time had for their object principally the security of the revenue and the convenient collection of duties.

ALEHOUSES. The adoption of efficient measures, for the regulation of houses appropriated to the sale of intoxicating liquors among the lower orders of the people, has been found to be absolutely necessary to the well-being of society. Upon practical subjects the experience of the past is always the best guide to an opinion for the future; and it may, therefore, be useful to trace, in a summary manner, the history of the laws in this country passed for the regulation of alehouses. By the common law it is as lawful to open a house for the sale of beer and ale as to keep a shop for the purpose of selling any other commodity; subject only to a criminal prosecution for a nuisance if his house be kept in a disorderly manner, by permitting excessive drinking, or encouraging bad company to resort thither, to the disturbance of the neighbourhood. As civilisation and population increased, this restriction was found insufficient; and so early as the 11 Henry VII. (1496) an Act was passed against 'vacabounds and beggers,' which empowered two justices of the peace "to reject and put awey comen ale-selling in tounes and places where they shall convenyent [convene], and to take suretie of the keepers of alehouses of their gode behavying, by the discrecion of the seid justices, and in the same to be avyed and aggreed at the tyme of their sessions." This seems to have been disregarded in practice: and by 5 & 6 Edward VI. c. 25, reciting that intolerable troubles to the commonwealth daily increased through such abuses and disorders as were had and used in common alehouses, power was given to magistrates to forbid the selling of beer and ale at such alehouses: and it was enacted that "none should be suffered to keep alehouses unless publicly allowed at the sessions, or by two justices; and the justices were directed to take security from all keepers of alehouses, against the using of unlawful games, and for the maintenance of good order therein." Authority is then given to the quarter sessions to inquire whether any acts have been done by alehouse keepers which may subject them to a forfeiture of their recognisances. It is also provided that "if any person not allowed by the justices, should keep a common alehouse, he might be committed to gaol for three days, and, before his deliverance, must enter into a recognisance not to repeat his offence; a certificate of the recognisance and the offence is to be given to the next sessions, when the offender is to be fined 20*s*." This statute formed the commencement of the licensing system, and was the first act of the legislature which placed alehouses under the control of the local magistrates.

In 1604 a statute was passed (2 Jac. I. c. 9) expressly, as its preamble states, for the purpose of restraining the "inordinate haunting and tippling in inns, alehouses, and other victualling houses." From this statute it is clear that in the time of James I., it was common for country labourers both to eat their meals and to lodge in alehouses.

The operation of the last-mentioned statute was limited to the end of the next session of parliament, in the course of which a statute (4 Jac. I. c. 4) was passed, imposing a penalty upon persons selling beer or ale to unlicensed alehouse-keepers; and by another statute (4 Jac. I. c. 5) of the same parliament, it was enacted that "every person convicted, upon the view of a magistrate, of remaining drinking or tippling in an alehouse, should pay a penalty of 3*s*. 4*d*. for each offence, and in default of payment be placed in the stocks for four hours." The latter statute further directs that "all offences relating to alehouses shall be diligently presented and inquired of before justices of assize, and justices of the peace, and corporate magistrates; and that all constables, ale-conners [ALE-CONNER], and other officers, in their official oaths shall be charged to present such offences within their respective jurisdictions."

The next legislative notice of alehouses is in the 7 Jac. I. c. 10, which, after reciting that "notwithstanding former laws, the vice of excessive drinking and drunkenness did more and more abound," enacts as an additional punishment upon alehouse-keepers offending against former statutes, that, "for the space of three years, they should be utterly disabled from keeping an alehouse."

The 21 Jac. I. c. 7, declares that the above-mentioned statutes, having been found by experience to be good and necessary laws, shall, with some additions to the penalties, and other trifling alterations, be put in due execution, and continue for ever.

A short statute was passed soon after the accession of Charles I. (1 Car. I. c. 4), which supplied an accidental omission in the statutes of James; and a second (3 Car. I. c. 3) facilitates the recovery of the 20*s*. penalty imposed by the statute of Edward VI., and provides an additional punishment, by imprisonment, for a second and third offence. At this point all legislative interference for the regulation and restriction of alehouses was suspended for more than a century.

The circumstances which led to the passing of the above-mentioned statutes in the early part of the reign of James I., and the precise nature of the evils alluded to in such strong language in the preambles, are not described by any contemporaneous writers. It appears, however, from the Journals, that these statutes gave rise to much discussion in both houses of parliament, and were not passed without considerable opposition. These laws never appear to have produced the full advantage which was expected. During the reign of Charles I. the complaints against alehouses were loud and frequent. In the year 1635 we find the Lord Keeper Coventry, in his charge to the judges in the Star Chamber previously to the circuits, inveighing in strong terms against them. (Howell's 'State Trials,' vol. iii. p. 835.) He says, "I account alehouses and tippling-houses the greatest pests in the kingdom. I give it you in charge to take a course that none be permitted unless they be licensed; and, for the licensed alehouses, let them be but a few, and in fit places; if they be in private corners and ill places, they become the dens of thieves—they are the public stages of drunkenness and disorder; in market-towns, or in great places or roads, where travellers come, they are necessary." He goes on to recommend it to the judges to "let care be taken in the choice of alehouse-keepers, that it be not appointed to be the livelihood of a great family; one or two is enough to draw drink and serve the people in an alehouse; but if six, eight, ten, or twelve must be maintained by alehouse-keeping, it cannot choose but be an exceeding disorder, and the family, by this means, is unfit for any other good work or employment. In many places they swarm by default of the justices of the peace, that set up too many; but if the justices will not obey your charge herein, certify their default and names, and I assure you they shall be discharged. I once did discharge two justices for setting up one alehouse, and shall be glad to do the like again upon the same occasion."

During the Commonwealth, the complaints against alehouses still continued, and were of precisely the same nature as those which are recited in the statutes of James I. At the London sessions, in August, 1654, the court made an order for the regulation of licences, in which it is stated that the "number of alehouses in the city were great and unnecessary, whereby lewd and idle people were harboured, felonies were plotted and contrived, and disorders and disturbances of the public peace promoted. Among several rules directed by the court on this occasion for the removal of the evil, it was ordered that "no new licences shall be granted for two years."

During the reign of Charles II. the subject of alehouses was not brought in any shape under the consideration of the legislature; and no notice is taken by writers of that period of any peculiar inconveniences sustained from them, though in 1682 it was ordered by the court, at the London sessions, that no licence should in future be granted to alehouse-keepers who frequented conventicles. Locke, in his 'Second Letter on Toleration,' published in 1690, alludes to their having been driven to take the sacrament for the sake of their places, or 'to obtain licences to sell ale.'

The next Act of Parliament on the subject passed in the year 1729, when the statute 2 Geo. II. c. 28, § 11, after reciting that "inconveniences had arisen in consequence of licences being granted to alehouse keepers by justices living at a distance, and therefore not truly informed of the occasion or want of alehouses in the neighbourhood, or the character of those who apply for licences," enacts that "no licence shall in future be granted but at a general meeting of the magistrates acting in the division in which the applicant dwells." At this period the sale of spirituous liquors had become common; and in the statute which we have just mentioned a clause is contained, placing the keepers of liquor or brandy-shops under the same regulations as to licences as alehouse-keepers. The eagerness with which spirits were consumed at this period by the lower orders of the people in England, and especially in London and other large towns, appears to have resembled rather the brutal intemperance of a tribe of savages than the habits of a civilised nation. Various evasions of the provisions of the licensing Acts were readily suggested to meet this inordinate demand; and in 1733 it became necessary to enforce, by penalty, the discontinuance of the practice of "hawking spirits about the streets in wheelbarrows, and of exposing them for sale on bulks, sheds, or stalls." (See 6 Geo. II. c. 11.) From this time alehouses became the shops for spirits, as well as for ale and beer; in consequence of which their due regulation became a subject of much greater difficulty than formerly; and this difficulty was increased by the growing importance of a large consumption of these articles to the revenue. Besides this, all regulations for the prevention of evils in the management of alehouses were now embarrassed by the arrangements which had become necessary for the facility and certainty of collecting the Excise duties.

In 1753 a statute was passed (26 Geo. II. c. 31), by the provisions of which, with some trifling modifications by later statutes, the licensing of alehouses continued to be regulated for the remainder of the last century. This statute, after reciting that "the laws concerning alehouses, and the licensing thereof, were insufficient for correcting and suppressing the abuses and disorders frequently committed therein," contains, among others, the following enactments:—1. That upon granting a licence to any person to keep an alehouse, such person should enter into a recognisance in the sum of 10*l.* with sufficient sureties, for the maintenance of good order therein. 2. That no licence should be granted to any person not licensed the preceding year, unless he produced a certificate of good character from the clergyman and the majority of the parish officers, or from three or four respectable and substantial inhabitants, of the place in which such alehouse is to be. 3. That no licence should be granted but at a meeting of magistrates, to be held on the 1st of September in every year, or within twenty days afterwards, and should be made for one year only. 4. Authority is given to any magistrate to require an alehouse-keeper, charged upon the information of any person with a breach of his recognisance, to appear at the next quarter-sessions, where the fact may be tried by a jury, and in case it is found that the condition of the recognisance has been broken, the recognisance is to be estreated into the Exchequer, and the party is utterly disabled from selling ale or other liquors for three years.

By a statute passed in 1808 (48 Geo. III. c. 143), a difference was introduced into the mode of licensing, not with a view to the internal regulation of alehouses, but for purposes connected with the collection of the revenue. The licence, which was formerly obtained from the magistrates, was, by that Act, to be granted by the commissioners, collectors, or supervisors of Excise, under certain specific directions, and upon the production by the applicant of a previous licence or allowance, granted by the magistrates, according to the provisions of the former statutes respecting licensing.

The next Act of Parliament upon this subject was passed in 1822 (3 Geo. IV. c. 77), but as that statute continued in operation for only a few years, it is unnecessary to specify its provisions further than to notice that the preamble states the insufficiency of the laws previously in force respecting alehouses, and that one of its provisions is considerably to increase the amount of recognisances required both from the alehouse-keeper and his sureties.

In 1828 a general Act to regulate the granting of alehouse licences was passed (9 Geo. IV. c. 61), which repealed all former statutes on this subject, and enacts a variety of provisions, of which the following are the most important:—1. Licences are to be granted annually, at a special session of magistrates, appointed and summoned in a manner particularly directed, and to be called the General Annual Licensing Meeting, to be holden in Middlesex and Surrey, within the first ten days of March, and in every other place between the 20th of August and the 14th of September. Any person who is refused a licence may appeal to the quarter-sessions; and no justice is to act in an appeal who was concerned in the refusal of the licence. 2. Every person intending to apply for a licence must affix a notice of his intention, with the name, abode, and calling of the applicant, on the door of the house, and on the door of the church or chapel of the place in which it is situated, on three several Sundays, and must serve a copy of it upon one of the overseers, and one of the peace officers. 3. If a riot or tumult happens, or is expected to happen, two justices may direct any licensed alehouse-keeper to close his house; and if this order be disobeyed, the keeper of the alehouse is to be deemed not to have maintained good order therein. 4. The licence is subjected to an express stipulation that the keeper of the house shall not adulterate his liquors; that he shall not use false measures; that he shall not permit drunkenness, gaming, or disorderly conduct in his house; that he shall not suffer persons of notoriously bad character to assemble therein; and that (except for the reception of travellers) he shall not open his house during divine service on Sundays and holydays. 5. Heavy penalties for repeated offences against the tenor of the licence are imposed; and magistrates at sessions are empowered to punish an alehouse-keeper, convicted by a jury of a third offence against the tenor of his licence, by a fine of 100*l.*, or to adjudge his licence to be forfeited.

The Act of Parliament, 11 Geo. IV. and 1 Wm. IV. c. 64, is entitled an "Act to permit the general sale of beer and cider by retail in England." The following are its most material provisions:—1. Any householder, desirous of selling malt liquor, by retail, in any house, may obtain an excise licence for that purpose, to be granted by the Commissioners of Excise in London, and by collectors and supervisors of excise in the country, upon payment of two guineas. 2. A list of such licences shall be kept at the Excise Office, and be at all times open to the inspection of the magistrates. 3. The applicant for a licence must enter into a bond with a surety for the payment of any penalties imposed for offences against the Act. 4. Any person licensed under the Act, who shall deal in wine or spirits, shall be liable to a penalty of 20*l.* 5. In cases of riot, persons so licensed shall close their houses upon the direction of a magistrate. 6. Such persons suffering drunkenness or disorderly conduct in their houses shall be subject to penalties which are to be increased on a repetition of the offence, and the magistrates before whom they are convicted may disqualify them from selling beer for two years. 7. Such houses are not to be opened before four in the morning nor after ten in the evening, nor during divine service on Sundays and holydays.

The effect of this statute was to withdraw the authority of granting licences to houses opened for the sale of ale, beer, and cider, from the local magistrates, in whose hands it had been exclusively vested for nearly 300 years, and to supersede their direct and immediate superintendence of such houses. The consequence of the facility of obtaining licences upon a small pecuniary payment, and without the troublesome and expensive process directed by former statutes, was a rapid multiplication of alehouses throughout the country, together with very general complaints, especially in the southern and western districts, and amongst the rural population, of a considerable increase of idleness and crime, and of increased and increasing demoralisation among the labouring classes of the people.

A discussion of the justice of these complaints would be foreign to the purpose of this article. It cannot however be too strongly impressed upon the minds of all, that it is a fatal error to consider this question strictly with a view to finance and revenue; these objects, momentous as they undoubtedly are, ought not to supersede those of much more weighty importance, as permanently affecting the moral and intellectual character, as well as the health, comfort, and independence of the lower orders. As a matter of finance, the encouragement of the use of intoxicating liquors is considered, by very competent judges, as of doubtful policy. "For government to offer encouragement to alehouses," says Sir Frederick Morton Eden, in his valuable 'History of the Poor,' "any further than they are wanted for the many useful purposes which they serve among the labouring classes, is to act the part of a *felo de se*. Nor ought the public ever to be lulled into an acquiescence by the flattering bait of immediate gain, which ere long they would be obliged to pay back to paupers, in relief, with a heavy interest."

By 4 & 5 Wm. IV. c. 85, the preamble of which recites that much evil has arisen from the management of houses, in which beer and cider are sold by retail under 1 Wm. IV. c. 64, it is enacted that each beer-seller is to obtain his annual excise licence only on condition of placing in the hands of the excise a certificate of good character, signed by six rated inhabitants of his parish, none of whom must be brewers or maltsters. Such a certificate is not to be required in towns containing a population of 5000 and upwards; but the house to be licensed is to be one rated at 10*l.* a year. This Act makes a difference between persons who sell a liquor to be drunk on the premises and those who sell it only to be drunk elsewhere.

By a Treasury order, beer sold at or under 1½*d.* a quart may be retailed without a licence: the officers of Excise are empowered to enter such houses and to examine all beer therein.

By the 3 & 4 Vict. c. 61, which amends both of the above Acts, a licence can only be granted to the real occupier of the house in which the beer or cider is to be retailed; and the rated value of such house is raised to 15*l.* in towns with a population of 10,000 and upwards; in towns of betwixt 10,000 and 2500, to 11*l.*; and in towns of smaller size the annual value is to be not less than 8*l.* Every person who applies for a licence must produce a certificate from the overseer of his being the real occupier of the house, and of the amount at which it is rated. A refusal to grant this certificate renders the overseer liable to a penalty of 20*l.*; and any person forging a certificate, or making use of a certificate knowing it to be false, is to forfeit 50*l.*

The hours for opening and closing beershops are now regulated by the above Act. In London and Westminster, and within the boundaries of the metropolitan boroughs, they are not to be opened earlier than 5 o'clock in the morning, and the hour of closing is 12 o'clock; but 11 o'clock in any place within the bills of mortality, or any city, town, or place not containing above 2500 inhabitants; and in all smaller places, 5 o'clock is the hour for opening, and 10 o'clock for closing.

Licensed victuallers, and keepers of beershops who sell ale to be drunk on the premises, are liable to have soldiers billeted upon them. Under the 'Metropolitan Police Act' (2 & 3 Vict. c. 37), which under certain conditions may be extended to within 15 miles of Charing Cross, all public houses are to be shut on Sundays until 1 o'clock in the afternoon, except for refreshment of travellers. Publicans supplying liquors to persons under sixteen years of age incur penalties.

The sale of beer and other liquors throughout Great Britain on Sunday, Christmas-day, and Good Friday, or other day appointed for a public fast or thanksgiving, is regulated by the 11 & 12 Vict. c. 49, and the 18 & 19 Vict. c. 118. No person may open his house for the sale of liquors before half-past 12 o'clock, or the termination of morning service, or between 3 and 5 in the afternoon, or after 11 o'clock or before 4 o'clock in the following morning, under the penalty of *5l.* Constables may enter the house at any time, and offenders may be summarily convicted.

ALEMBIC, a chemical vessel used in distillation. Various forms of it have been devised; the simplest consists of a *body, cucurbit*, or *matrass*, which serves as a boiler; a *head* or *capital*, with a pipe and a receiver.

Sometimes all these parts are made of glass, and the head and receiver are usually so; when the body is of this material, it is fitted to the head by grinding; but the apparatus, in this case, is extremely expensive, and very liable to accident. When the body is made of metal, the glass head is secured to it by almond or linseed meal lute.

The fluid to be distilled having been put into the body, the head being fitted to it, and the receiver adapted to its pipe, heat is applied to the body either by a lamp or a sand-bath; the vapour which rises is condensed in the head, and, falling into a depressed channel, runs through the pipe into the receiver, loosely fitted to it with a cork. If the receiver be kept partly immersed in cold water, the condensation will be more readily and economically effected. Sometimes the head is perforated, and furnished with a stopper; by removing this, a supply of the fluid to be distilled may be poured into the body, without disturbing the luting by which the body and head are kept in close contact. An alembic of this kind is not very useful for the general purposes of distillation; it can scarcely be applied to the preparation of acids; and for distilling spirit or water, a retort or a still is much to be preferred. An alembic of this form, the body of which is made of silver, and the head and receiver of glass, is sometimes employed for distilling the spirit from the alcoholic solutions of potash and soda, in the process of purifying these alkalies.

The most ancient alembics were made of metal, and generally of tinned copper; the annexed figures represent that proposed by Baumé in his 'Elements of Pharmacy,' with very slight alteration. It is com-

posed of several parts: *a*, Fig. 1, represents the *cucurbit, body*, or *boiler*, which is made of tinned copper; *b* is a short pipe by which the boiler is replenished with the fluid to be distilled, during the operation, and without disturbing or unluting the apparatus. When in operation, the pipe *b* is stopped with a cork.

Fig. 2 is a section of the *head* or *capital*, which fits into *a*, and is secured by lute; it is divided into two parts, which do not communicate with each other; *c* contains cold water, which, by cooling the vapour that rises from the boiler *a* into *d*, causes it to condense into a fluid, which runs down into a small gutter, and is by it conveyed through the pipe *e* into a receiver; *f* is a cock by which the water is let out from *c* when it becomes hot by condensing the vapour.

Fig. 3 represents a *worm* or *serpentine*, *g*, into which is conveyed the vapour that may escape condensation in *d*; it is surrounded by cold water in the vessel *h*, which, as it becomes hot, is let out near the top of the vessel, and a fresh supply of cold water introduced near the bottom; the condensed vapour is received at the end of the worm in the receiver *k*. The cock *i* serves to remove the whole of the water from the vessel *g*.

Fig. 4 represents a *water-bath*, also made of tinned copper; it fits into the body *a*, and is heated by the medium of the boiling-water contained in the space between it and *a*, instead of the fire directly applied. When the water-bath is used, the head, Fig. 2, is fitted into it in the manner already described with respect to the body *a*, Fig. 1.

Fig. 5 shows the whole apparatus placed in the furnace, with the worm attached to the pipe of the head.

The alembic, in the form now described, is but little used; the addition of the worm surrounded with cold water has rendered it unnecessary to employ any refrigeratory round the head; and the apparatus thus simplified is the common still, which will be described under the article DISTILLATION.

ALEUROMETER. One of the novelties of 1849 was a contrivance called an Aleurometer, invented by M. Boland, a Paris baker, for ascertaining the panifiable or bread-making qualities of wheaten flour. This determination depends upon the expansion of the gluten contained in a given quantity of flour when freed from its starch. A ball of gluten being placed in a cylinder to which a piston is fitted, the apparatus is exposed to a temperature of 150°; and as the gluten dilates, its degree of dilatation is marked by the piston-rod. The greater the dilatation, the better is the flour fitted for making bread.

ALEXANDRA, one of the group of small planets revolving between Mars and Jupiter. [ASTEROIDS.]

ALEXANDRIAN CODEX, a manuscript of the Old and New Testament, in Greek, now preserved in the British Museum. It was sent by Cyrillus Lucaris, patriarch, first of Alexandria, then of Constantinople, to Charles I.; was placed in the royal library in 1628; and continued there until that collection was removed to the British Museum in 1753. The history of the manuscript, before its transfer to Charles I., is involved in much uncertainty; and the real age and value of it have been much controverted. These points have been minutely discussed by Dr. Woide, formerly librarian of the British Museum, who published a fac-simile of the New Testament, in his preface. He is a staunch advocate of the excellence of the manuscript. A second edition of the preface ('Notitia Codicis Alexandrini') was published by Spohn, who controverted many of Woide's opinions, showed that the manuscript was by no means free from blunders of transcription, and reduced both its age and authority to a much lower standard.

The manuscript is contained in four volumes, of the shape and size of large quarto, of which the New Testament fills the last. It is written on vellum, in double columns, in uncial or capital letters, without spaces between the words, accents, or marks of aspiration. The letters are round and well formed. Some words are abbreviated, but they are not very numerous. There is a variety both in the colour of the ink and the form of the letters. The manuscript is on the whole in good condition, but sometimes the ink has eaten through the parchment; the shape of the letters however can generally be traced; sometimes the ink itself has scaled off.

The New Testament has been more fully described and more carefully collated than the Old; from which however Grabe published his splendid edition of the Old Testament, Oxford, 1717–20. They are uniform in appearance and execution, but the Old Testament seems to be in rather better condition. It contains, besides all the canonical and most of the apocryphal books found in our editions, the third and fourth books of the Maccabees, the Epistle of Athanasius to Marcellinus, prefixed to the Psalms, and fourteen hymns, the eleventh in honour of the Virgin. Ecclesiasticus, the Song of the Three Children, Susannah, and Bel and the Dragon, do not appear to have formed part of the collection. The New Testament contains the genuine epistle of Clement to the Corinthians, and part of the other which has been attributed to him. This is the only known manuscript in which the genuine epistle exists. A fac-simile of the Old Testament has been published by the Rev. H. Baber, of the British Museum.

ALEXANDRIAN LIBRARY, a collection of books, formed by Ptolemæus, the first king of Egypt, and probably the largest which was made before the invention of printing. It is said to have been founded about B.C. 284, in consequence of the suggestions of Demetrius Phaléreus, who had seen the public libraries at Athens. Demetrius was appointed superintendent of the new establishment, and busied himself diligently in collecting the literature of all nations, Jewish, Chaldee, Persian, Ethiopian, Egyptian, &c., as well as Greek and Latin. Eusebius says, that at the death of Ptolemæus Philadelphus there were 100,000 volumes in the library. It was situated in the quarter of Alexandria called Brucheion. Philadelphus purchased the library of Aristotle, and it was increased by his successors. Almost all the Ptolemies were patrons of learning; and at last the Alexandrian

Library is said to have amounted to 700,000 volumes. But the rolls (*volúmina*) spoken of contained far less than a printed volume; as, for instance, the 'Metamorphoses' of Ovid, in fifteen books, would make fifteen volumes. This consideration will bring the number of books within the bounds of credibility.

After the capture of Alexandria by Julius Cæsar a large part of the library was burnt. Gibbon (chap. xxviii.) asserts that the old library was totally consumed, and that the collection from Pergamus, which was presented by Marcus Antonius through Cleopatra, was the foundation of the new one, which continued to increase in size and reputation for four centuries, until, at the destruction of the Serapeion by Theophilus, patriarch of Alexandria, it was dispersed, A.D. 390. Still the library was re-established; and Alexandria continued to flourish as one of the chief seats of literature till it was conquered by the Arabs in 640. The library was then burnt, according to the story generally believed, in consequence of the fanatic decision of the Khalif Omar,—"If these writings of the Greeks agree with the Book of God, they are useless, and need not be preserved: if they disagree, they are pernicious, and ought to be destroyed." Accordingly, it is said, they were employed to heat the 4000 baths of the city; and such was their number, that six months were barely sufficient for the consumption of this precious fuel. (Gibbon, chap. li.) Gibbon has employed his ingenuity to discredit this account, which in itself appears by no means improbable. The library was at all events dispersed, if not destroyed; it ceased to exist as a public institution.

Connected with the library of Brucheion was a college, or retreat for learned men, called the Museum, where they were maintained at the public expense, in unbroken leisure, and with every facility for the pursuit of knowledge. This establishment was subsequently transferred to the Serapeion, and continued to flourish till the destruction of the temple by Theophilus. The sciences of mathematics, astronomy, and geography, were especially cultivated: witness the names of Euclid, Apollonius, Eratosthenes; and, in later times, of Ptolemæus the geographer. Criticism, philology, and antiquities, were also much studied. [ALEXANDREIA, in GEOG. DIV.] Alexandria continued, until its capture by the Saracens, one of the most noted seats of learning in the world.

(*Acad. des Inscriptions*, tom. ix. p. 397; Gibbon, chap. li., and the original authorities quoted in these works.)

ALEXANDRINE VERSE, a species of verse so called from having been first employed, according to some authorities, in a French translation, by Alexander de Paris and Lambert Lieon, of a Latin poem called the Alexandriad, according to others in an original work in the former language, on the life of Alexander the Great, composed by these poets in association with Jean le Nivelois and others. After its first introduction, it appears to have fallen for a long time into disuse among the French poets, until it was revived by Jean Antoine de Bœuf (one of the seven called the Pleiades), in the reign of Francis I. The first, however, who attuned the national ear of France to this verse, was the celebrated Ronsard, since whose time it has become the regular heroic verse of the French language: or that in which all their epic, tragic, and other greater poetical works are composed. It consists of twelve syllables, subject to the rule that it shall always be broken into two regular hemistichs, or, in other words, that its sixth syllable shall always terminate a word. The English Alexandrine verse consists in like manner of twelve syllables; but among us it has been rarely used throughout a whole poem. The longest and most remarkable poetical work in our language, written wholly in Alexandrine verse, is Drayton's 'Polyolbion.' In general, it is employed only occasionally in poems written in our usual heroic verse of ten syllables, and never except in the concluding line of the couplet or triplet. In Dryden, by whom it has been used in this manner most frequently, and with the finest effect, it most commonly winds up a triplet—such as that in which Pope has at once described and exemplified the manner of his great predecessor:

> "Waller was smooth; but Dryden taught to join
> The varying verse, the full resounding line,
> The long majestic march, and energy divine."

The Alexandrine verse in English also forms the closing line of what is called the Spenserian stanza. Regularly, it ought always, as in French, to be divisible into two hemistichs; but, in the freer spirit of our poetry, this rule is occasionally violated.

ALGAROTH, or ALGAROTTI, POWDER OF. [ANTIMONY, OXYCHLORIDE OF.]

ALGEBRA. This word is derived by contraction from the Arabic phrase *Al jebr e al mokâbalah*, the nearest English translation of which is *restoration and reduction*. So short a definition is of course useless; we shall endeavour to give the first and most simple view of this science, our limits not permitting us to go, even in the smallest degree, into its operations.

In establishing the rules of arithmetic, it is always necessary to use general reasoning: that is, reasoning the nature of which would not be altered if other numbers had been chosen, different from those which were really employed in the question. For example, if 2 acres let for 13*l.*, how much will 17 acres let for? It is shown immediately that the number of pounds required is that obtained by multiplying 13 and 17 together, and dividing the product by 2: and it appears moreover, that, by the same reasoning, a similar rule might be established when the numbers are different from those given above, provided the form of the question remain the same. That is, if any number of acres we please to name, cost a certain number of pounds, the price of any other number of acres may be found by multiplying that other number by the number of pounds the first acres cost, and dividing by the number of the first-mentioned acres. Thus we have established a general rule, and the steps by which we translate this into an algebraical expression are as follows. We invent short signs, to signify that multiplication and division are to take place: we express the former by putting × between the numbers which are to be multiplied together, the latter by writing the divisor under the dividend, and drawing a line between them. The foregoing rule then stands as follows:

$$\left\{\begin{array}{l}\text{Price in pounds of}\\ \text{second No. of acres.}\end{array}\right\} \text{ is } \frac{\text{Second No. of acres} \times \left\{\begin{array}{l}\text{Price in pounds of}\\ \text{first No. of acres.}\end{array}\right\}}{\text{First No. of acres.}}$$

So far we have abbreviated by using two *symbols of operation;* to which we may add that we write + between two numbers which are to be added together, and — between two numbers of which the second is to be taken away from the first. Now suppose that, to catch the eye, we put a letter whenever a number is named in the question, in order that by looking for that letter we may quickly find out in what part of the result the aforesaid number is used. For example: If a certain number of acres (a) cost a certain number of pounds (b), how many pounds will another number of acres cost (c)? The answer is, as above,

$$\frac{\text{Second No. of acres } (c) \times \left\{\begin{array}{l}\text{Price in pounds of}\\ \text{first No. of acres.}\end{array}\right\} (b)}{\text{First No. of acres } (a)}$$

The last step is, to let the letters themselves stand for the several numbers, which will save the necessity of writing words in the result. Our final algebraical way of writing the question will then be—If a acres cost b pounds, how much will c acres cost? The answer is,

$$\frac{c \times b}{a} \text{ pounds, usually written } \frac{c\,b}{a} \text{ pounds.}$$

To take another instance, which we first write algebraically: If a pounds of sugar, at m pence a pound, be mixed with b pounds of sugar, worth n pence a pound, the worth of a pound of the mixture is

$$\frac{m\,a + n\,b}{a + b} \text{ pence,}$$

which in the usual language cannot be stated more shortly than as follows:—To find the worth of a pound of mixed sugar, knowing how much of each sort was in the mixture, and how much each was worth per pound, multiply the number of pounds of each sort by the number of pence which a pound of it costs, add the products together, and divide by the whole number of pounds in the mixture.

This will be sufficient to give the reader an idea of the notation of algebra, and the very great abbreviation which it introduces into the details of processes. For further explanations, see ADDITION, &c., POSITIVE, NEGATIVE, EQUALITY, EXPONENT, INDEX, POWER, ROOT, and the article NOTATION.

We have said nothing of the reasoning of algebra, because it differs in no respect from that of arithmetic, or any other science, at least in the elementary part. It proceeds upon such fundamental and self-evident principles as the following:—that two equal numbers remain equal when the same number has been added to or subtracted from them, or when they have been both multiplied or both divided by the same number—that no number is altered by the addition of any number followed by the subtraction of the same, or by being multiplied by any number, if the product be afterwards divided by the same number; and so on. To take a very simple case, suppose we ask, What number is that, which multiplied by 3 and the product increased by 6, gives 30? Without knowing the number, we can see that if three times the number, together with 6, gives 30, three times the number must be 24, or the number required must be the third part of 24, or 8. The algebraical method of expressing this is as follows, where = means that the numbers between which it is placed are the same.

Let x stand for the number; then by the question

$$\begin{array}{ll} & 3\,x + 6 = 30 \\ \text{Therefore } 3\,x & = 30 - 6 = 24 \\ \text{or } x & = \dfrac{24}{3} = 8 \end{array}$$

We give the preceding, not as a specimen of the advantages of algebra, but of its language only, for we have purposely chosen such a question as needs no assistance, in order to make the method of expression more evident. [AXIOM; EQUATION; PROBLEM.]

The operations of algebra are to be considered in a very different light from those of arithmetic. In the latter science, absolute numbers are given, and an absolute number is sought: in the former it is rather the nature of the question which is given, and it is required to find, not so much the answer to any particular case, as a general method of solving any case whatever. The symbols used are not numbers, but *general* representations of them, that is letters, each of which may stand for any number we please, provided that it keeps the same meaning throughout the question. Hence in what are called addition, multiplication, &c., of algebraical quantities, we do not ask, 'What *number* does this multiplication give,' but '*what set of operations* are equivalent to, and, if we please, may supply the place of, this multiplication?' For example, suppose it occurs in a question that one number is to be added to, as well as subtracted from, another, and that the two results are to be multiplied together. Let a and b stand for the two numbers, of which let a be the greater. So long as we use *general* symbols, that is, so long as we do not assign some particular numbers, which a and b are to signify, we cannot perform the above operations, but can only indicate them by the marks above mentioned; for example, $a+b$ stands for the sum of a and b, $a-b$ for the difference, and

$$(a+b) \times (a-b)$$

for the product of this sum and difference. So far we need nothing more to tell us what to do, so soon as a and b shall have their values assigned to them: for instance, if a be 7, and b be 3, $a+b$ is 10, and $a-b$ is 4, and the above product is 10×4, or 40. But, in the meanwhile, we see in the above a sort of double operation: there is inside each pair of brackets something to be done, while the results of the brackets themselves are connected by a further process. It is asked then, what simple processes will supply the place of the preceding, so that whatever numbers a and b may stand for, the product of this sum and difference may be obtained from them? The answer to this is obtained by the process of algebraic *multiplication*, and proves to be $aa-bb$, or b multiplied by itself, and the result subtracted from a multiplied by itself. In the preceding example, this is $7 \times 7 - 3 \times 3$, or $49-9$, or 40, as before. For details of various operations, see the general heads already quoted, and BINOMIAL THEOREM, DEVELOPMENT, SERIES.

The earliest treatise on algebra of which we can fix the date within two centuries is that of Diophantus, an Alexandrian Greek, who lived in the sixth century. It is very unlike a modern treatise on algebra, being almost destitute of general symbols, and consisting altogether of a species of problems which have since received the name of *Diophantine*, in which it is required to solve certain questions, the answers to which shall be whole numbers only. It is so like the Hindoo algebra in its character, that it is impossible to suppose the two wholly unconnected. But as the Hindoo algebra is of a much higher cast than that of Diophantus, we are obliged to suppose, either that Diophantus obtained from the East a part of their knowledge, or that the Hindoos, setting out with the Greek algebra only, made considerable improvements after the sixth century. As the Hindoo algebra has been very much extolled by some, and more than proportionally cried down by others, we quote from Delambre, who is distinguished among the latter. "The Hindoos had algebra of the first and second degrees; they knew how to solve indeterminate problems; and they made these acquisitions themselves; they are also the authors of the system of arithmetic now universally received by us."—'Histoire de l'Astronomie Ancienne, vol. i., p. 556. To these we might add many minor points, and also that, in the solution of indeterminate equations of the second degree, they had made as much progress as ever was made in Europe before the middle of the eighteenth century. [VIGA GANITA, in BIOG. DIV.]

The Persians and Arabs confessedly derived their knowledge of the subject from the Hindoos. We do not, however, find that they proceeded as far as their masters: for the Arabic treatises, so far as we know, contain only the solution of equations of the first and second degree, and their application to various arithmetical questions, excluding all mention of indeterminate equations.

It was by means of the treatise of Mohammed Ben Musa, who lived in the time of the Caliph Al Mamun, that the science was introduced into Europe. A complete and able translation of this work, by Dr. Rosen, with the original Arabic, was published in 1831, by the Oriental Translation Fund.

Thus much of the science was introduced into Europe, or rather into Italy only, at the beginning of the thirteenth century, by Leonardo Bonacci of Pisa. Algebra lay dormant in Italy, without receiving any material improvement, till the middle of the sixteenth century, when it was introduced into Germany, France, and England, nearly about the same time by Stifelius, Peletarius, and Robert Recorde, respectively. The Hindoos, instead of using the letters of the alphabet, designated various unknown quantities by the names of different colours; the Persians and Arabs employed the word answering to 'thing' in their language for the unknown quantity, and the Italians adopted the word '*cosa*' for the same purpose: hence algebra came to be called the *Regola de la Cosa* in Italy, and the *Cossike Art* in England. It is to be observed, however, that in no country, up to the time of Vieta, were letters used to signify anything but quantities sought; those *given* being always certain numbers, and never arbitrary representations of numbers in general. Hence the simple word '*thing*,' or any abbreviation of it, was sufficient for their purpose.

While algebra was being introduced into the various countries of Europe, the Italians began to make the first steps towards its improvement. The solution of an equation of the third degree was discovered by CARDAN and TARTAGLIA; that of the fourth by FERRARI; while various other discoveries were made by BOMBELLI and MAUROLICO. We must refer the reader to the several lives of these mathematicians, in the BIOG. DIV. of this work. VIETA, a Frenchman, who died in 1603, made the grand improvement of using letters to stand for known as well as unknown quantities, and with the additional power derived from this improvement, laid the first steps of the general theory of equations. In England, HARRIOT, who died in 1621, carried on and extended the discoveries of Vieta; and from the time of the two latter we must date the modern form of the science.

Our limits will not allow us even to name the crowd of discoverers who have extended this branch of pure mathematics since the time of Vieta. We must refer to the work of Hutton already cited, to Bonnycastle's translation of Bossut's 'Histoire des Mathématiques,' or to the original work itself: to the preface of the mathematical part of the French Encyclopædia; or to the histories of Montucla and Cossali. The first and second are the most likely to fall in the way of the English reader. Libri's 'History of Italian Science' has much information on early Italian algebra; and several very ancient treatises have been recently printed, for the first time, by Prince Boncompagni.

The only necessary preliminary to the study of algebra is a good knowledge of the four rules of arithmetic, and of common and decimal fractions. Without so much it is impossible to read any work with profit; and in the want of it we must look for the reason why the science appears repulsively dry to most persons. On this subject, we refer the student to some remarks in page 59 of the treatise on the 'Study of Mathematics' published by the Society for the Diffusion of Useful Knowledge.

We shall now give some notion of the form which algebra has taken in the last thirty years. Instead of attempting to make our work of reference supply the place of a school-book, we prefer to give those to whom the common elementary work was unnecessary, some of the notions which are gradually enlarging the boundary of the science, and assisting, beyond what was once imagined possible, in clearing the difficulties which it presented to reflecting minds.

1. In *pure arithmetic* the subject matter is simple number. Its symbols are 0, implying the absence of all number; 1 or unity; 2, the abbreviation of $1+1$; 3, that of $1+1+1$, &c. Also the symbols $+ \; - \; \times \; \div$ and those of powers and roots. All these symbols have specific meanings, and the symbols of operation are connected with known operations. There are also *general* symbols of number, a, b, c, &c., definite but not specific: that is, each one stands for a different number, known or unknown, throughout any one train of thought, though it need not represent the same number in all investigations.

2. The fundamental direct symbols of operation, seen in $a+b$, ab or $a \times b$, a^b, are connected with inverse operations, seen in $a-b$, $\frac{a}{b}$ or $a \div b$, $\sqrt[b]{a}$ or $a^{\frac{1}{b}}$. Each inverse operation offers certain difficulties; those of $a \div b$ are overcome by the introduction of the notion of fractions; those of $\sqrt[b]{a}$ by the considerations in LIMIT, applied to what is called the approximate extraction of roots. But $a-b$ presents cases of absolute impossibility, as in $3-7$; and this impossibility is incapable of being removed as long as the symbols are the symbols of pure arithmetic.

3. The rules by which operations of pure arithmetic are performed are found to be capable of classification under five heads: no step in any train of thought leads to anything but the use of one of these five simple rules, or of complex rules obtained by their combination. Of course these rules are understood as applied only when they give intelligible results.

I. *Rule of signs.*—Whenever two of the signs + and — both act upon any symbol, the result is that like signs give +, unlike signs give —.

II. *Convertibility of additions and subtractions,* as in $a+b-c=a-c+b=-c+a+b$, &c.

III. *Convertibility of multiplications and divisions,* as in $\frac{a}{b} \times c = \frac{a \times c,}{b}$, &c.

IV. *Distributiveness of multiplications and divisions,* as in $a(b+c-d) = ab+ac-ad$, and $\frac{c+d}{a} = \frac{c}{a} + \frac{d}{a}$.

V. *Rules of exponents.* These are $a^b \times a^c = a^{b+c}$, $a^b \div a^c = a^{b-c}$, $a^b c^b = (ac)^b$, and $(a^b)^c = a^{bc}$.

Every master of the use of these rules can perform all the steps of an arithmetical operation, including all that is commonly called algebraical, but provided that no steps enter except those which are arithmetically intelligible. Even the common rules of computation, so far as they are not acts of mere memory or trial, consist in uses of the first four rules.

4. On examining problems into which the impossible subtraction enters, whether in process or result, whether from inconsistency in the problem or in the mode of solving it, the impossibility is always to be traced to a diametrically wrong sense put upon the meaning of some one quantity, as reading gain for loss, or ascent for descent, &c. And since the impossible subtraction can always be reduced to the form $0-a$, or $-a$ (thus $3-7$ is $3-3-4$, or -4), and since this is found always to require, as a correction, that a units should be taken of the sort *diametrically opposite to what was supposed when* $0-a$ *was being*

found, it suggests itself to let $+1$ and -1 mean, not merely the addition and subtraction of 1, but any two opposite kinds of units whatever, addition and subtraction being only one of the infinite number of opposite meanings which may be signified.

5. Extensive induction shows, not only that the five rules remain true when the last augmentation of meaning is adopted, but that the want of symbolic distinction between the different meanings of $+$ and $-$ is of no consequence whatever. Complete opposition of character in $+$ and $-$ is all that is necessary to the permanence of the rules; and $+1$ may stand in the same problem for a unit of gain, a unit of ascent, a unit of future time, a unit of addition, &c.; while -1 stands for a unit of loss, a unit of descent, a unit of past time, a unit of subtraction, &c.

6. The algebra thus established, having all the processes of pure arithmetic, *and no more*, and completely containing pure arithmetic within its range of subjects (for $+1$ and -1 mean addition and subtraction of 1, as well as other things), may be called *single algebra*. Space of one dimension (length) is, so to speak, wide enough for it: if $+1$ signify a unit measured in one direction upon a straight line from a given point, then -1 signifies a unit measured in the opposite direction. Every positive and negative quantity may find its interpretation in this line.

7. On proceeding to ulterior results, it is found that the extension of meaning which is sufficient to admit such symbols as $3-7$ or $0-4$ within the range of intelligible quantities will not do the same for their roots of the second, or fourth, or any even order. Thus, even in the complete single algebra, $\sqrt{-1}$, $\sqrt[4]{-1}$, &c., are as void of meaning as $4-7$ in pure arithmetic: they are not positive quantities; they are not negative quantities; and there are no other sorts. Under the name of *impossible quantities* they were long used without being understood, because they were found to lead to true results. Some defended them on different theories, but the sentiment of Professor Woodhouse must have been the one which guided the class of mathematicians who think on first principles; "since they lead to true results, they *must have a logic*." The question was to find that logic: and till it was found, a great part of algebra was *art*, not *science*.

8. Since it has appeared that extension of meaning has succeeded in clearing away one class of difficulties, the means of removing the rest must probably be sought in further extension; but it will give a better idea of the subject to begin by throwing away all meanings, treating the symbols as symbols only, subject to certain five rules of operation. Let the only symbol which retains its meaning be $=$, denoting the identity of what precedes with what follows. We then stand thus: Let it be granted that there are certain symbols, 0, 1, a, b, c, &c., and symbols of connection, $+ - \times \div a^b$ (we cannot here dispense with the letters, since the symbol consists in the manner of placing the letters): let $0+a$ and a be synonymes, and also $0-a$ and $-a$, and $1\times a$ and a, and $a\div 1$ and a: let $1+1$ be abbreviated into 2, $2+1$ into 3, &c.: let $+a-a$ be 0, and let $\times a \div a$ be equivalent to $\times 1$: let the five rules in § 3 be perfectly and universally true, and let a, b, &c., be competent to represent (among other things, perhaps) 0, 1, 2, &c., or any formations from them or from one another. Let no idea of meaning be attached, for the present, to any symbol or to any of the words by which operations are described. Required all manner of methods of forming symbols which must be considered as identical. The collection of such methods is *symbolical algebra*, nothing but symbols and prescribed laws of use. For instance, required a necessary transformation for $(a+b)(c+d)$. By the fourth rule this is $(a+b)c+(a+b)d$, which, by the third rule, is $c(a+b)+d(a+b)$, which again, by the fourth rule, is $ac+bc+(ad+db)$, or $ac+bc+(+ad)+(+db)$, which, by the first rule, is $ac+bc+ad+db$. This symbolical algebra is not a science, but an art: it may be illustrated as follows: Suppose a person to join the pieces of a boy's dissected map by the backs, without looking at the countries engraved on the fronts; he is then going through the dead and (by itself) uninstructive process of symbolical algebra; the pieces are his symbols, the forms of the edges are his rules for guidance. But another, who turns the map the right way, and puts the countries which he knows into their right places at once, and helps himself to the position of those which he does not know by trying to fit edges together, is going through the improving process of geographical acquirement, which corresponds to an algebra with meanings attached to the symbols. Symbolical algebras may be invented without end: how many of them would be worth anything for the value of their possible systems of meaning, is another question. We avowedly make a retrograde step when we introduce symbolical algebra; we throw away the arithmetic and single algebra which suggested the symbols and their rules, and retain for the moment only the unmeaning symbols and their laws of combination.

9. The next step is, given the symbols, rules, and consequent trains of legitimate transformation, of a system of symbolic algebra, how many and what systems of meanings may be attached to the symbols, so that all the fundamental rules may be true of those meanings, and all the symbolic identities which follow from those rules may be necessary consequences, also with intelligible meanings. Every such system of meanings, superadded to the symbolical algebra, is a *logical algebra*, or one in which every process of transformation is a reasoning or a collection of reasonings. In all probability there is an infinite number of logical algebras to every self-consistent system of symbolical algebra: we merely note down the list of those which have hitherto been traced from the ordinary system, originally suggested by arithmetic. Since these sentences were first written, Professor Boole, in his 'Laws of Thought,' has shown that all the processes of logic, actual or possible, are capable of representation under the symbols of common algebra, and the rules of common algebra.

I. *Pure arithmetic*, in which the subject matter is number. II. *Single algebra*, in which the symbols represent numbers derived from concrete magnitude, considered as being, in every case, of one or another of two diametrically opposite kinds. III. *Double algebra*, the main subject of the present remarks, in which each symbol represents a line of definite length, and in some definite direction out of the infinite number which may be taken *in one plane*. IV. *Triple and quadruple* * *algebra*, in which the directions are not confined to one plane (this subject is in its earliest infancy). V. The *geometry* of the second book of Euclid, and the corresponding solid geometry. Here AB actually means the area of the rectangle under the lines A and B, and ABC the content of the rectangular parallelopiped (or right solid) under the lines A, B, and C: the fundamental rules can be demonstrated, and propositions can rigorously be proved. The ordinary and incomplete mode of demonstrating the second book of Euclid might thus be rendered unobjectionable. VI. The *calculus of operations*, in which the symbols, or as many of them as we choose, are ***not magnitudes at all***, but directions to perform certain operations on a variable quantity. [OPERATION.]

10. It does not follow that every species of logical algebra admits of explanation for every symbol or combination of symbols. Thus I. just mentioned rejects $0-1$; II. rejects $\sqrt{-1}$; III. is perfect; and IV. may perhaps be made so: in V. AB + C means no more than AB, if it have meaning, and A^B is wholly inexplicable; and VI. is incumbered with difficulties of new and serious kinds as soon as its elements are passed. It may happen that the proper meaning of a symbol or formula cannot be assigned at the commencement of a logical algebra, but can afterwards be deduced from its symbolic consequences. When this is the case, the deduced meaning must not disturb any one of the five rules. This process is the *interpretation* to which we have alluded, and symbols of which the meaning is laid down from the commencement may be said to be *explained*.

11. It is impossible that a perfect algebra can be founded on ideas of time, loss and gain, or any in which only two directions can be imagined. Space, from the infinity of directions which it admits, is, as yet, the only perfect medium of explanation. Time before and time after a certain epoch may be represented by the positive and negative quantity, but what is there in the idea of time to which $\sqrt{-1}$ can possibly apply? Again, show us a commercial operation which, performed upon a gain, produces a sort of result which can neither be called gain nor loss, but which repeated *two* or more times upon a gain, turns it into a loss—and we can immediately construct a system of commercial algebra, in which $\sqrt{-1}$ shall be intelligible. But, as yet, the necessary ideas are found in geometry only, which causes some persons to object to the extension of algebra. But these surely forget that even common single algebra must derive its theory of oppositions from concrete quantity; -1, standing alone, is unintelligible in the science of pure number.

12. Remark the manner in which [RELATION] the definitions of $a+b$ and ab can be given, even in arithmetic, in terms of process, without mention of subject-matter: $a+b$ requires us to proceed from a as we proceed from 0 to form b: ab requires us to proceed with a as we should with 1 to form b.

13. Let the common symbol of algebra signify a length in a direction in a certain plane, change either of length or direction demanding change of symbol. Take a point O for the *zero point* or *origin*, and let 0 signify that we do not leave that point. From O draw any line at pleasure for the *axis of length*, and take a length OU upon it for 1: continue the unit axis both ways. Draw a perpendicular though O to the axis of length, and call it the *axis of direction*: the reasons for these terms will appear in the sequel.

14. Let A + B denote the distance and direction from the origin which is gained by going over first A and then B; and let A − B denote that gained by going over first A and then a line equal and contrary in direction to B. Let AB denote a line whose length has units equal to the product of the units in the lengths of A and B, and the sum of the angles which they make with the unit line for the angle it makes with the unit line. Similarly, let A ÷ B have the quotient of the lengths of A and B for its length and the difference of the angles for its angle. These definitions are fully explained in NEGATIVE, &c., and RELATION.

15. From the last it appears as an actual consequence of definition, that − A means simply a line equal and opposite to A: and also that $+1+1$ or $+2$ can mean nothing but 2 units extended on the unit-side of the axis of length, and so on; while -2 means 2 units extended on the opposite side of the axis of length. It also appears that A + B and A − B are the operations of single algebra whenever

* By the quadruple algebra we mean Sir W. Hamilton's *quaternions*, which we call quadruple because its author calls it so; but inasmuch as it finds its complete interpretation in space of three dimensions, we consider it as *triple*. Its symbolic rules are not altogether those of ordinary algebra.

the two lines are in the same direction. And if all lines be on the axis of length, all the four operations are those of single algebra; while, if they be all on the unit-side of the axis of length, there is nothing but pure arithmetic; except when an impossible subtraction obliges us either to reject the process, or to enlarge the definition and pass to the opposite side of the axis of length.

16. Make a positive and negative direction on the axis of direction, thus: Choose a direction of revolution in which a line revolving round the origin, and setting out from the axis of length, shall be said to revolve positively. Let the unit revolve positively, and let the first side of the axis of direction which it meets be considered the positive side of that axis. Let the opposite direction of revolution be called negative. But if any difficulty arise about the use of negative angles, remember that this is merely matter of convenience, and can as well be dispensed with. Four right angles may be added to any angle of direction, without altering the direction indicated: and it is perfectly indifferent whether we speak of —160° in the negative direction, or + 200° in the positive direction.

17. By $A = (a, \alpha)$, let us agree to mean that A signifies a line of a units of length, inclined at an angle α to the positive side of the axis of length. Use the theoretical mode [ANGLE] of measuring angles. Then (a, α), $(a, \alpha \pm 2\pi)$, $(a, \alpha \pm 4\pi)$, &c., are all representations of the same line A. The peculiar symbols of the new algebra, so long as they are wanted, shall be capital letters; small letters denoting the symbols of the single algebra.

18. The first four of the fundamental rules in § 3 may be easily shown to be true. The geometrical propositions principally required are two. First, that any number of lengths being given and their directions, if we set off from a point through those lengths and in those directions, one after the other, we reach one and the same point in whatever order the lines of progress are taken. Secondly, that if any polygon revolve about one of its angular points, while at the same time the sides and diagonals which meet in that point are all changed in the same ratio, the figure always remains similar to what it was at the outset. With these propositions and the following,

$$(a, \alpha) \times (b, \beta) = (ab, \alpha+\beta) \quad \frac{(a, \alpha)}{(b, \beta)} = \left(\frac{a}{b}, \alpha - \beta\right),$$

which are merely expressions of the definitions, there will not be much difficulty in establishing the first four of the rules.

19. Let the square, cube, fourth power, &c., of A, as yet, be denoted in full by AA, AAA, AAAA, &c., and their corresponding roots by $\sqrt{A}$, $\sqrt[3]{A}$, $\sqrt[4]{A}$, &c. There is then no difficulty in establishing, as in NEGATIVE, &c., that the mth power of the nth root of (a, α) is derived from

$$\left(\sqrt[n]{a^m},\ \frac{m\alpha \pm 2k\pi}{n}\right)$$

k being any integer; that $\sqrt[n]{A}$ has n values and no more; that $\sqrt{-1}$ stands for a unit on one side (say on the positive side) of the axis of direction, and $-\sqrt{-1}$ for a unit on the negative side. Also, as in the article cited, that, if p and q be the projections of A, on the axis of length and direction, that A is identical in meaning with $p + q\sqrt{-1}$ and with $a(\cos\alpha + \sin\alpha \,.\, \sqrt{-1})$. Indeed, at this point it will be advisable for the student to review the imperfect system in NEGATIVE, only reading exponents as is done just above, powers at full length, roots with the old radical sign.

20. Why do we not hitherto admit the exponent, and define A^2 to mean AA, &c.? Because we are not prepared with a definition which will include *all* exponents. In the article just cited, we get the meaning of $\epsilon^{\theta\sqrt{-1}}$ by interpretation, and it seems only a sort of accident that it should have an intelligible meaning. In order to provide beforehand a complete definition of the exponent, which shall make $(a + b\sqrt{-1})^{c+d\sqrt{-1}}$ as fully explained as any other symbol, *ab initio*, we must premise knowledge of the arithmetical theory of Naperian LOGARITHMS, and must lay down the definition of a line which answers to, and performs all the functions of, a *logarithm*. But as it is inconvenient to retain this name, let us substitute for it the word *logometer*, reserving the word *logarithm* for arithmetical use. By λA, the logometer of A or (a, α), is meant a line of which the projections on the axes* of length and direction are $\log a$ and α; a line, in fact, of the length $\sqrt{(\log a + \alpha^2)}$ inclined to the unit-line at an angle whose tangent is $\alpha \div \log a$. Conversely, the line whose logometer is B or (b, β) has $b\cos\beta$ for the logarithm of its length, and $b\sin\beta$ for the angle (number of theoretical units in the angle). Every line has an infinite number of logometers; for the angle α may be read as $\alpha \pm 2m\pi$, where m is any integer; and thus we have an infinite number of logometers, hypothenuses to a set of right-angled triangles, whose common base is $\log a$ on the axis of length. But no logometer belongs to more than one primitive line.

21. The logometer has the fundamental properties of a logarithm: thus $\lambda A + \lambda B = \lambda(AB)$, meaning that any logometer of A added (bear in mind the extended meaning of all terms of operation) to any logometer of B gives one of the logometers of AB. We shall endeavour to give short heads of demonstration to this and the following propositions. It is readily shown that the projections of two lines on either axis must be added (with their proper signs) to give the projection of the sum. Now in $\lambda A + \lambda B$, the sums of the projections are $\log a + \log b$ and $\alpha + \beta$; but the projections of $\lambda(AB)$ or $\lambda(ab, \alpha+\beta)$ are by definition $\log(ab)$ and $\alpha+\beta$; whence the proposition follows.

22. Denoting by ϵ, as usual, the base of Napier's logarithms, it is easy to see that $(\epsilon, 0)$ has the simple unit line for one of its logometers, or $(1, 0)$, or 1; also that $\theta\sqrt{-1}$ is one of the logometers of a unit of length inclined at the angle θ, or of $(1, \theta)$, or of $\cos\theta + \sin\theta \,.\, \sqrt{-1}$. And by ϵ we must agree to mean (ϵ, o), never $(\epsilon, 2\pi)$, &c.

23. Now let A^B be defined to mean the line which has for one of its logometers B multiplied into any one of the logometers of A: accordingly A^B has as many meanings as we can derive different lines by this process from the different logometers of A. And we shall show, first, that the fundamental rules are satisfied by this definition; secondly, that whenever B means a length of b units *in the axis of length*, the symbol A^B is exactly the A^b of common algebra. It is sufficiently obvious that A^B has meaning or meanings for all possible assigned lengths and directions of A and B.

24. Since ϵ^A means the line whose logometer is $A\lambda\epsilon$ or A, it follows that $\epsilon^{\lambda A}$ is the same as A. Hence $\epsilon^{B\lambda A}$ is the same as A^B, the line whose logometer is $B\lambda A$.

25. The sum of $B\lambda A$ and $C\lambda A$ (the logometers of A^B and A^C) is $(B+C)\lambda A$, which is, by definition, the logometer of A^{B+C}. Hence A^{B+C} and $A^B A^C$, having the same logometers, are identical. Again, $A^B C^B$ has for its logometer $B\lambda A + B\lambda C$ or $B\lambda(AC)$, which is also the logometer of $(AC)^B$; hence $A^B C^B$ and $(AC)^B$ are identical. Thirdly, the logometer of $(A^B)^C$ is $C \times \lambda(A^B)$ or $C \times B \times \lambda A$, which is also the logometer of A^{BC}: hence $(A^B)^C$ and A^{BC} are identical. Consequently the fifth fundamental rule is true of A^B as here defined.

26. Let B be a line on the axis of length, represented by $(b, 0)$ or (b, π) according as it is positive or negative. Then $B\lambda A$ is made simply by multiplying the length of λA by b, and leaving it otherwise unaltered in the first case, or turning it through two right angles in the second. In the first case the projections of $B\lambda A$ are b times those of λA, in the second they have also their signs changed. In the first case then $b\log a$ and $b\alpha$ are the projections of the logometer of A^B, or A^B is $(a^b, b\alpha)$, agreeing with A^b in common algebra: in the second case A^B is $(a^{-b}, -b\alpha)$, agreeing with A^{-b}.

27. The meaning of $\epsilon^{\theta\sqrt{-1}}$ is the line whose logometer is $\theta\sqrt{-1} \times \log(\epsilon, 0)$, or $\theta\sqrt{-1}$. This line is $(1, \theta)$, or $\cos\theta + \sin\theta \,.\, \sqrt{-1}$, whence the equation

$$\epsilon^{\theta\sqrt{-1}} = \cos\theta + \sin\theta \,.\, \sqrt{-1} \;\ldots\; (\theta)$$

is a necessary consequence of the various trains of definition. Now, as all we know of these trains of definition is that the meanings of the symbols satisfy the five rules in § 3, it may seem to be too much that so remarkable an equation as the last should be actually involved in the definitions, instead of being the result of a long sequence of reasonings. And in truth it is too much in one point; for since all our preceding reasoning on the subject of A^B would apply equally to any base we might choose for logarithms, and any unit for measuring angles, what have we done but prove the preceding equation true for any base and any angular unit? And we reply that so far as the definition of A^B is concerned, our proof is perfectly general: but that, on looking back, we find a restrictive connection between the logarithmic base and the angular unit, as follows: It is very easy to see that in our prior definitions, the equation

$$\{(1, \theta)\,.\,(1, \theta)\,.\,(1, \theta)\ \ldots\ (m \text{ times})\} = (1, m\theta)$$

leads to the following

$$\{\cos\theta + \sin\theta \,.\, \sqrt{-1}\}^m = \cos m\theta + \sin m\theta \,.\, \sqrt{-1}$$

in which we may use m as an exponent, since for the simple integer, representing a line in the axis of length, the definition in § 23 gives $A^m = AAA \ldots (m \text{ times})$. Let θ be the angular unit; then we have

$$(\cos 1 + \sin 1 \,.\, \sqrt{-1})^m = \cos m + \sin m \,.\, \sqrt{-1}.$$

But the last is $\epsilon^{m\sqrt{-1}}$, if we introduce the complete exponent from § 23; therefore it must be an equation of connection between ϵ and the mode of assigning angle 1, that

$$\epsilon^{m\sqrt{-1}} \text{ should be } (\cos 1 + \sin 1 \,.\, \sqrt{-1})^m$$

* Any two perpendicular lines would do; but to choose any other except the axis of length and direction would be a step precisely equivalent to preferring some other base to the Naperian in the logarithms of common algebra.

for all integer values of m: and this not merely from equation (θ) but from comparison of what $\cos 1 + \sin 1 . \sqrt{-1}$ must mean in the definitions prior to that of the exponent, with the complete exponential meaning of $\epsilon^{\sqrt{-1}}$. Hence we must have ϵ, the base of the logarithms, connected with the angular unit by the equation

$$\epsilon^{\sqrt{-1}} = \cos 1 + \sin 1 . \sqrt{-1}$$

and any base and angular unit which satisfy this condition will do. The most simple way of doing this is to take $\epsilon = 2{\cdot}71828 \ldots$ as usual, and the angular unit such that there shall be π or $3{\cdot}14159 \ldots$ units in two right angles: but if any one should prefer $\sqrt[2]{(2{\cdot}71828 \ldots)}$ for a base, and $\pi \times 3{\cdot}14159 \ldots$ for the number of units in two right angles, he might get into trouble, but not into error.

28. Another difficulty of the sort which arises when the result seems above the means employed in the demonstration is, that we have a complete system of trigonometry ready for demonstration by mere algebraical mechanism, without casting a further thought on the meaning of the symbols $\cos\theta$ and $\sin\theta$, or more on those of $\tan\theta$, $\cot\theta$, $\sec\theta$, $\operatorname{cosec}\theta$, than to make them, by definition, severally mean, $\sin\theta \div \cos\theta$, $\cos\theta \div \sin\theta$, $1 \div \cos\theta$, and $1 \div \sin\theta$. All we have done with $\cos\theta$ and $\sin\theta$ is to take them into our system as expressing the numerical values of the projections of a unit inclined at the angle θ upon the axes of length and direction. We have not even directly used $\sin^2\theta + \cos^2\theta = 1$. But it should be remembered, that in proving generally $A(B+C) = AB + AC$, we have used the property of *similar figures*; an assumption which is quite sufficient to be the basis of the demonstration of Euclid I. 47, on which $\sin^2\theta + \cos^2\theta = 1$ depends. And those who attentively read Euclid see that he does, in the sixth book, prove I. 47 over again, without any use of it, in showing that all similar figures described on the three sides of a right-angled triangle have the two smaller together equal to the greater. [HYPOTHENUSE.]

In the above definition of $\sin\theta$ and $\cos\theta$ it is clear that $\cos(-\theta) = \cos\theta$ and $\sin(-\theta) = -\sin\theta$, whence the first of the following, being universally true, gives the second:

$$\epsilon^{\theta\sqrt{-1}} = \cos\theta + \sin\theta . \sqrt{-1}$$

$$\epsilon^{-\theta\sqrt{-1}} = \cos\theta - \sin\theta . \sqrt{-1}$$

Whence we have

$$(\cos\theta + \sin\theta \sqrt{-1})(\cos\theta - \sin\theta . \sqrt{-1}) = \epsilon^0$$

Now ϵ^0, by definition, has $0 \times \lambda\epsilon$, or 0×1, or 0, for its logometer, and is therefore $(1, 0)$ or 1. And the first side is, by common application of rules, $\cos^2\theta + \sin^2\theta$. If any one, instead of merely applying rules to the equation

$$(\cos\theta + \sin\theta . \sqrt{-1})(\cos\theta - \sin\theta . \sqrt{-1}) = 1,$$

should proceed to demonstrate the rules upon this instance, he would, in a circuitous way, be led to a perfect geometrical demonstration of $\sin^2\theta + \cos^2\theta = 1$.

29. No equation of this system, which hitherto admits of expression, presents any difficulty as to the meaning of its sides, or any combination of symbols for which the meaning is to be found by interpretation. Perhaps one of the most remarkable results of the ancient system of algebra is the equation

$$\pi = \frac{\log(-1)}{\sqrt{-1}}$$

Some algebraical writers have stated that -1 has neither square root nor logarithm, and without further warning, have afterwards made the non-existent logarithm, divided by the non-existent square root, give the ratio of the circumference of a circle to its diameter. Others have given fair warning that, in using what they called imaginary quantities, they were appealing, more or less, to experience; seeing that operations so conducted always led to truth, when, by the ultimate disappearance of $\sqrt{-1}$, the result could be interpreted. They were content to use such an equation as $\pi\sqrt{-1} = \log(-1)$ as an instrument of which the power was known, though its mechanism was concealed. In the complete system it is visibly obvious that $\pi\sqrt{-1}$ is *one* of the logometers of -1, or of $(1, \pi)$.

30. In ordinary working, there is no objection to dropping the distinction between the logometer and the logarithm, there being no difference between the two in operations.

For fuller account of the whole of this system, we refer to De Morgan, 'Trigonometry and Double Algebra.'

That this system will finally be introduced into elementary instruction we entertain no doubt whatever. But how soon will this take place? The school-books hardly yet teach the interpretation of the negative quantity; so that there is but little hope of the speedy success of the complete system. But truth must conquer at last; and the respect with which the memory will be preserved of the mathematicians who were neither discouraged by the difficulties nor rendered incredulous by the mysteries of the ancient system, will not protect from ridicule those who shall obstinately refuse to see light because there was once darkness, or shall wilfully continue in the imperfect system from which those who wish the exact sciences to be in all their parts the perfection of reason are most glad to be delivered. With respect to those parts of the doctrine of series, and of the integral calculus, which still present difficulties, though of a different character from those here treated, the lesson taught by the victory over what was rashly called *impossible*, which many heads have required many years to gain, is—Never refuse to examine, and to continue in the examination of, all consequences of the symbolic laws of algebra: there is every reason to hope that the symbols are always right, even though the views of their explanation may require correction.

ALGEBRAIC. An expression is said to be *algebraic*, as distinguished from *transcendental*, when its number of terms is finite, and when each term contains only addition, subtraction, multiplication, division, and extraction of roots, the exponents of which are given. Thus all infinite series, as well as expressions containing

$$\log. x,\ a^x,\ \sin x,\ \cos x,\ \&c.$$

though used in algebra, in the widest sense of the word, are improperly said to be not *algebraic*, but *transcendental*. Similarly, a curve is said to be *algebraic* when its equation (CURVE) contains no transcendental quantities.

ALGEBRAIC GEOMETRY. A name given to the application of algebra to the solution of geometrical problems. For the principal points of interest connected with it, see ABSCISSA, ORDINATE, CO-ORDINATES, CURVE, CURVATURE, EQUATION, TANGENT. The regular treatises in this, as in every other case, cannot be dispensed with by any of our readers who are desirous of acquiring it. But in this article, as in the last, we are led to write by the paucity of elementary works which explain a new and useful modification of the mode of viewing a part of the subject.

In geometry of two dimensions, the number of co-ordinates is not so great as to make symmetrical disposition extremely necessary at the outset. We should not, for instance, gain much by forming the equation of the straight line thus: $ay + bx + c = 0$ instead of $y = ax + b$; in fact, the writers who have preferred the symmetrical course have rather overloaded themselves with symbols, to an extent which makes the burden thus imposed on the memory greater than that from which symmetry relieves it. But it is not so in geometry of three dimensions. There are here three co-odinates to every point; and, as it happens, symmetry, even when obtained by augmentation of the number of symbols, is found to be, on the whole, an assistance in the remembrance of formulæ. Accordingly, the equations of the plane and straight line, and formulæ connected with them, are expressed with great convenience in the manner of which the following is a summary; the first use of which, as far as we know, is found in the celebrated work of Malus, 'Théorie de la double Réfraction,' 4to, Paris, 1810.

1. In arranging expressions containing three quantities or different sets of three, symmetry requires that no one letter shall ever appear at the beginning of one expression without appearing at the end of another; and that in every set of expressions which are formed by combination of pairs, an interchange of any two letters, or of the corresponding pairs taken out of different sets, shall reproduce the same set of expressions in another order, or at most with different signs. Thus, $a-b$, $b-c$, $c-a$, are symmetrical, and so are $ay-bx$, $bz-cy$, $cx-az$.

2. When there are two equations of the form $ax+by+cz=0$, $a'x+b'y+c'z=0$, the quantities are not given, but their proportions are: and x, y, and z are in the proportion of

$$bc'-cb',\ ca'-ac',\ ab'-ba'$$

3. An expression of the form

$$(ay-bx)^2+(bz-cy)^2+(cx-az)^2$$

is identical with

$$(a^2+b^2+c^2)(x^2+y^2+z^2)-(ax+by+cz)^2$$

4. The form of the equation of a plane is $Ax+By+Cz+D=0$; the common form $z = Ax+By+C$ is unsymmetrical. The plane which passes through the point whose co-ordinates are p, q, r, which call the point $(p\,q\,r)$, is

$$A(x-p)+B(y-q)+C(z-r)=0$$

The plane which passes through the three points $(p\,q\,r)$, $(p'\,q'\,r')$, $(p''\,q''\,r'')$, is

$$\left\{(q'-q)(r''-r)-(r'-r)(q''-q)\right\}(x-p)+\&c.=0:$$

one term of which is enough; symmetry will point out the rest. Remember the order pq, qr, rp.

5. When such symmetrical expressions as $ab'-ba'$, $bc'-cb'$, $ca'-ac'$, are to be constructed, the best way is to write down a, b, c, a, and a', b', c', a', under one another, and to calculate from the left to the end, without returning to the beginning. Thus from

$$\begin{array}{cccc} 8 & 1 & 3 & 8 \\ 2 & 4 & 6 & 2 \end{array}$$

we have

$$30,\ -6,\ -42$$

6. The most convenient form of the equations of a straight line is as follows: Let (abc) be a point on the straight line, and let A B C be any three quantities proportional to the cosines of the angles which the straight line makes with the directions of x, y, z. Then the equations of the straight line are

$$\frac{x-a}{A} = \frac{y-b}{B} = \frac{z-c}{C}$$

The following system is sometimes convenient :—

$$x = a + \mathrm{A}v,\ y = b + \mathrm{B}v,\ z = c + \mathrm{C}v$$

where $v\sqrt{(\mathrm{A}^2+\mathrm{B}^2+\mathrm{C}^2)}$ is the distance between (abc) and (xyz).

7. The plane whose equation is $\mathrm{A}(x-a)+$&c. $=0$ may be called the plane (ABCabc), and the straight line just mentioned may be called the straight line (ABCabc). Throughout this article capitals are generally proportional to cosines of angles, and small letters are co-ordinates of points. The order of co-ordinates is xyz, and all letters connected with co-ordinates run in consecutive triplets, as ABC, PQR, &c. But when triplets of pairs are made, as AB, BC, CA, then AB particularly belongs to the co-ordinate to which C is attached, BC to that of A, and CA to that of B.

8. The angles made by the straight line (ABC, &c.) with the axes have for their cosines $\mathrm{A} \div \sqrt{(\mathrm{A}^2+\mathrm{B}^2+\mathrm{C}^2)}$, &c.; and the angle made by the two straight lines (ABC, &c.), (A′B′C′, &c.), has for its cosine

$$\frac{\mathrm{AA}' + \mathrm{BB}' \times \mathrm{CC}'}{\sqrt{(\mathrm{A}^2+\mathrm{B}^2+\mathrm{C}^2)}\sqrt{(\mathrm{A}'^2+\mathrm{B}'^2+\mathrm{C}'^2)}}$$

When the lines are perpendicular, $\mathrm{AA}'+\mathrm{BB}'+\mathrm{CC}'=0$; and when they are parallel, A, B, C are in the same proportion as A′, B′, C′.

9. The angles made by the plane (ABC, &c.) with the planes of yz, zx, and xy, are $\mathrm{A} \div \sqrt{(\mathrm{A}^2+\mathrm{B}^2+\mathrm{C}^2)}$, &c.; the cosine of the angle made by the planes (ABC, &c.) and (A′B′C′, &c.) with one another is as in the last, and also the conditions of perpendicularity and parallelism.

10. The plane (ABCabc) is at right angles to the line (ABCpqr), whatever a, b, c, p, q, r may be. And the plane (ABC, &c.) is at right angles to the line (A′B′C′, &c.) whenever A, B, C, are proportional to A′, B′, C′. But the plane (ABC, &c.) is parallel to the line (A′B′C′, &c.) when $\mathrm{AA}'+\mathrm{BB}'+\mathrm{CC}'=0$.

11. The straight line (ABCabc) lies entirely in the plane (PQRpqr) when

$$\mathrm{P}(a-p) + \mathrm{Q}(b-q) + \mathrm{R}(c-r) = 0$$
$$\mathrm{AP} + \mathrm{BQ} + \mathrm{CR} = 0.$$

12. The intersection of the two planes (PQRpqr) and (P′Q′R′$p'q'r'$) is the straight line (ABCabc) in which A, B, C, are proportional to $\mathrm{QR}'-\mathrm{RQ}'$, $\mathrm{RP}'-\mathrm{PR}'$, $\mathrm{PQ}'-\mathrm{QP}'$ and

$$\mathrm{P}(a-p) + \mathrm{Q}(b-q) + \mathrm{C}(c-r) = 0$$
$$\mathrm{P}'(a-p') + \mathrm{Q}'(b-q') + \mathrm{C}'(c-r') = 0$$

13. The intersection of the plane (PQRpqr) and the straight line (ABCabc) is at the point whose co-ordinates are $a+\mathrm{A}v$, $b+\mathrm{B}v$, $c+\mathrm{C}v$, where

$$v = \frac{\mathrm{P}(p-a) + \mathrm{Q}(q-b) + \mathrm{R}(r-c)}{\mathrm{AP} + \mathrm{BQ} + \mathrm{CR}}$$

14. Two straight lines (ABCabc) and (A′B′C′ $a'b'c'$) do not, generally speaking, intersect at all; their shortest distance is $(\mathrm{BC}'-\mathrm{CB}')(a-a')+$&c., divided by $\sqrt{\{(\mathrm{BC}'-\mathrm{CB}')^2+\text{\&c.}\}}$, and they meet when the numerator of this fraction is nothing. The plane (PQRpqr) is parallel to both straight lines when P, Q, R, are proportional to $\mathrm{BC}'-\mathrm{CB}'$, $\mathrm{CA}'-\mathrm{AC}'$, $\mathrm{AB}'-\mathrm{BA}'$.

15. The equation of a plane which passes through the straight line (ABCabc) and is perpendicular to the plane (PQRpqr) is

$$(\mathrm{BR}-\mathrm{CQ})(x-a) + (\mathrm{CP}-\mathrm{AR})(y-b)$$
$$+ (\mathrm{AQ}-\mathrm{BP})(z-c) = 0.$$

16. The perpendicular distance from the point (abc) to the plane (PQRpqr) is $\mathrm{P}(a-p)+\mathrm{Q}(b-q)+\mathrm{R}(c-r)$ divided by $\sqrt{(\mathrm{P}^2+\mathrm{Q}^2+\mathrm{R}^2)}$, independently of sign. And the perpendicular distance between the parallel planes (PQRpqr) and (PQR$p'q'r'$) is $\mathrm{P}(p-p')+$ &c., divided by $\sqrt{(\mathrm{P}^2+\text{\&c.})}$

17. The perpendicular from the point (lmn) upon the straight line (ABCabc) meets it in a point of which the co-ordinates are $a+\mathrm{A}v$, &c., where

$$v = \frac{\mathrm{A}(l-a) + \mathrm{B}(m-b) + \mathrm{C}(n-c)}{\mathrm{A}^2+\mathrm{B}^2+\mathrm{C}^2};$$

and the square of the length of that perpendicular is

$$(l-a)^2 + \text{\&c.} - \frac{\{\mathrm{A}(l-a) + \mathrm{B}(m-b) + \mathrm{C}(n-c)\}^2}{\mathrm{A}^2+\mathrm{B}^2+\mathrm{C}^2}.$$

This is sufficient for a specimen of the method, and even for a summary of the most important propositions respecting the straight line and plane. On the good effect of symmetry it is hardly necessary to make much remark; not only are formulæ more easily remembered, since the whole can be formed from recollection of a part—and more easily used, since an unsymmetrical result is an indication of error—but the actual expression can be shortened in type, of which the above is a sufficient proof. It would have been impossible safely to write down as many results in twice the space, if the ordinary plan of notation had been adopted. The best mode of treating the ordinary forms for the straight line, such as $y = ax + \alpha$, $z = bx + \beta$, is to reduce them to the preceding, thus:

$$\frac{x-0}{1} = \frac{y-\alpha}{a} = \frac{z-\beta}{b}$$

ALGORITHM, a corruption from the Arabic, the root being a word which means calculation, or at least refers to calculation or reckoning. When the Indian numerals were introduced from the East, this word came with them, and the new figures were denominated (by Chaucer for example) *augrime* (or algorithm) figures. The word is tolerably well naturalised among the French mathematicians, as meaning the system of notation: thus there is an algorithm of functions, and an algorithm of the differential calculus, &c. It has also been used by English writers, but our language does not want it; the word *notation* does just as well. Hard words sometimes lead to misconception; those who attempt to interpret them find them not only spelt in different ways, but with very different meanings. Daniel Fenning (‘Young Algebraist's Companion,’ 1750) tells us that some writers are so short and intricate, that it is almost impossible to learn the *algorithm* from them, much less the *algorism*. In a note he informs us that the first of these hieroglyphics means the first principles, and the second their application to practice. Our old mathematical dictionaries define the word algorithm in probably its real imported sense, namely, as meaning the great rules of arithmetic.

ALGUACIL, an officer in Spain, answering to the English bailiff. The name is from the Arabic *el-vazil*, or from the Hebrew verb *gazal*, which means to catch. The alguacil mayor is a superior officer, whose functions are the same as those of the common alguacil. The duty of an alguacil is at present confined to the apprehension of criminals; the office of executioner being discharged by the verdugo.

ALIAS, a term used in legal proceedings to denote a second or further description of a person who has gone by two or more different names. If the same person is known by the name of John Smith as well as the name of John Thomson, he is described in legal language as John Smith, *alias dictus* (otherwise called) John Thomson.

ALIBI, a Latin term signifying "in another place," of frequent occurrence in criminal courts. Thus, where a person charged with an offence committed at a certain time and place, shows that he was *elsewhere* at that time, he is said to prove an *alibi*. If true, this is obviously the best proof of innocence; but no kind of defence offers so ready an opportunity for false evidence: and the *setting up an alibi* is therefore, in practice, always regarded with suspicion.

ALIEN. An alien is one who is born out of the legiance (allegiance) of the king. (Littleton, 198.) The word is derived from the Latin, *alienus*; but the word used by the English or other law writers in Latin is *alienegena*. The condition of an alien, according to this definition, is not determined by place, but by allegiance [ALLEGIANCE], for a man may be born out of the realm of England, or without the dominions of the king, and yet he may not be an alien. It is essential to alienage that the birth of the individual occurred in a situation and under circumstances which gave to the sovereign of this country no claim to his allegiance.

The following instances will serve to illustrate the description of an alien. The native subject of a foreign country continues to be an alien, though the country afterwards becomes a part of the British dominions. Thus, persons born in Scotland *before* the accession of James I., were aliens in England even *after* that event; but those who were born afterwards were adjudged to be natural-born subjects. This question was the subject of solemn discussion in the reign of that prince; and the reported judgment of the court has guided lawyers in all similar controversies. Persons born in those parts of France which formerly belonged to the crown of England, as Normandy, Guienne, and Gascony, were not considered as aliens so long as they continued so annexed; and, upon the same principle, persons born at this day in any of our colonial possessions are considered native subjects. A man, born and settled at Calais whilst it was in the possession of the English, fled to Flanders with his wife, then pregnant; and there, after the capture of Calais by the French, had a son; the issue was held to be no alien. If, however, enemies invade the kingdom, and a child is born among them, the child is an alien.

The children of ambassadors, and other official residents in foreign states, have always been held natives of the country which they represent and in whose service they are. This rule prevailed even at a time when the law was stricter than it now is. It has been since so far extended by various enactments, that all children born abroad, whose *fathers*, or *grandfathers* on the father's side, were natural subjects, are now deemed to be themselves natural-born subjects, unless their fathers were liable to the penalties of treason or felony, or were in the service of a prince at war with this country. (25 Ed. III. st. 2; 7 Anne, c. 5; 4 Geo. II. c. 21; 13 Geo. III. c. 21.) The children of a British *mother* by an alien, though aliens if born out of the king's allegiance, are now enabled to take property by devise, purchase, or succession. (7 & 8 Vict. c. 66.)

The children of aliens born in England are, as a general rule, the same as natural-born subjects; they are entitled to the same rights and owe the same allegiance.

It follows from the general principles of our law that a man may be subject to a double and conflicting allegiance; for, though he may become a citizen of another state (the United States of America, for instance), or the subject of another king, he cannot divest himself of the duty which he owes to his own. So that, in the event of a war between the two states, he can take no active part on behalf of one, without incurring the penalty of treason in the other. This predicament may occur without any fault of the party; for the children of aliens are (except under peculiar circumstances) natural subjects of the state in which they were born: yet they may still be regarded as natural-born subjects of the state to which their parents owed allegiance.

An alien cannot hold lands in England, except for a term not exceeding twenty-one years, and in that case only for the purpose of residence or trade. (7 & 8 Vict. c. 66.) If he purchase lands, he takes them, but they are forfeited to the crown after the fact of purchase has been ascertained by a jury. These disabilities of an alien are founded on the nature of the tenure of land in England, which always implies fealty to some superior lord. It follows from the notion of an alien, that he cannot take land by descent, nor can he be entitled to land by the courtesy of England. An alien woman was not at common law entitled to dower of her husband's lands, unless she had been either made a denizen or naturalised. It is said that she was entitled to dower if she had married an Englishman by licence from the crown. (Cruise, 'Digest,' i. 159.) Now, however, an alien woman by marriage with a British subject is *ipso facto* naturalised. (7 & 8 Vict. c. 66.) It has been said that an alien cannot take land by devise; but there seems to be no legal principle which shall prevent him from *taking* by devise, any more than from taking by purchase: the only question is, for whose benefit he *takes*, for he cannot hold it for his own benefit. An alien cannot be returned to serve on a jury, except where he is one *de medietate linguæ*, that is, a jury of which one-half are foreigners.

An alien may possess himself of goods, money in the funds, and other personal effects, to any extent. The law has, from a very early period, recognised his right to reside without molestation within the realm for commercial purposes. "All merchants shall have safe and secure conduct to go out and to come into England; and to stay there, and to pass as well by land as by water, to buy and sell by the ancient and allowed customs, without any evil tolls, except in time of war, or when they are of any nation at war with us." ('Magna Charta,' art. 48.) Notwithstanding which express provision, aliens were formerly subject to higher duties at the custom-house, and several statutes prohibited alien artificers from working for themselves in this kingdom. Aliens cannot hold British registered shipping nor shares therein. (17 & 18 Vict c. 104, s. 18.) An alien cannot be a member of parliament, nor can he vote in the election of a member of parliament. The Municipal Corporations Act (5 & 6 Wm. IV. c. 76, s. 4), also debars aliens from exercising the municipal privileges of a burgess.

An alien can bring an action or suit in the English courts in respect of personal property or contracts; and may dispose of his property by will. The *droit d'aubaine*, or right of succeeding to the effects of a deceased alien, formerly claimed by the crown of France, never prevailed in this country. Nor was it customary to enforce it even in France, except as against the natives of a state in which a similar right was exercised. For some time previous to its abolition by the first Constituent Assembly in 1791, it was generally stipulated by foreign countries in their treaties with France, that their subjects should be exempt from the law. [AUBAINE.] This doctrine of reciprocity was adopted by the French Code ('Code Civil,' art. 726), but was abrogated in 1819, so far as the right of succession is concerned: so that aliens are now on the same footing in this respect with native Frenchmen throughout that kingdom. Aliens who are subject to any criminal proceeding in our courts of justice are in most cases entitled to trial by a jury *de medietate linguæ*.

The disabilities of aliens may be partially removed by letters-patent constituting the party a free denizen. From the date of the grant he is entitled to hold land, and transmit it to his after-born children, and to enjoy many other privileges of a native subject. The partial effect of Letters of Denization give rise to the practice of obtaining naturalisation by act of parliament, which conferred on the alien every right of a natural-born subject, except the capacity of sitting in parliament or the privy council, or of holding grants and offices of trust under the crown; an exclusion originally dictated by the jealous policy of the legislature on the accession of the House of Orange. A temporary naturalisation may now, however, be obtained by the order of the Home Secretary. [DENIZEN.]

The rights of aliens, enumerated above, must be understood to apply only to alien *friends*. Alien *enemies*, or subjects of a foreign state at war with this country, are in a very different condition, and may be said to possess very few rights here.

As examples of the policy which has at different times been pursued in this country with reference to aliens, the following historical notices may be interesting:—

Magna Charta stipulates, in the article already cited, for the free access of foreign merchants for the purposes of trade, and its provisions were enforced and extended under the reigns of succeeding princes.

In the 18th year of Edward I. the parliament rolls contain a petition from the citizens of London, "that foreign merchants should be expelled from the city, because they get rich, to the impoverishment of the citizens;" to which the king replies, that "they are beneficial and useful, and he has no intention to expel them."

In the reign of Edward III. several beneficial privileges were conferred on aliens for the encouragement of foreign trade.

Under Richard II. and his successor, statutes were made imposing various restraints on aliens trading within the realm, and especially prohibiting internal traffic with one another. Similar restrictions were introduced in the reign of Richard III., chiefly with a view to exclude them from retail trade; and in that of Henry VIII. violent insurrections against aliens were followed by repeated statutes, reciting the mischievous consequences attributed to the influx of foreigners, and laying greater impediments in the way of their settlement within the realm. Several Acts of this description are still in force, though they have fallen into practical disuse; but the courts of law have always put on them a construction the most favourable to foreign commerce, agreeably to the opinion of Lord Chief Justice Hale, that "the law of England hath always been very gentle in the construction of the disability, and rather contracting than extending it severely." (Ventris's 'Reports,' vol. i. p. 427.)

In the reign of James I. the king was strongly petitioned to adopt exclusive measures against the aliens, who had flocked into the kingdom from the Low Countries; but James, though he acquiesced to a certain extent in the object of the petitioners, seems by no means to have participated in their feelings of enmity to aliens; for he professes his intention "to keep a due temperament between the interests of the petitioners and the foreigners;" and he especially commends "their industrious and sedulous courses, whereof he wished his own people would take example."

In the reign of Charles II. aliens were invited to settle in this country, and to engage in certain trades, by an offer of the privileges of native subjects. (15 Charles II. c. 15.) This statute was repealed by 12 & 13 Wm. III. c. 2; but there is an unrepealed Act of 6 Anne, which naturalises all foreigners who shall serve for two years on board any ship of her majesty's navy or a British merchant-ship.

In the early part of the last century (1708) a bill was brought into parliament for the general naturalisation of all foreign Protestants, upon their taking certain oaths and receiving the sacrament in any Protestant church, and it passed notwithstanding the strenuous opposition of the city of London, who represented that they would sustain loss by being obliged to remit certain dues which aliens were obliged to pay. After remaining in operation for three years, it was repealed on a suggestion of its injurious effects upon the interests of natural-born subjects; but a previous bill for effecting this object was rejected by the Lords. The reasons for and against the measure will be found in the fourth volume of Chandler's 'Commons' Debates,' p. 119-122. In 1748 and 1751, a measure similar to the Act of 1708 was brought forward, and in 1751 it was read a second time, but was dropped in consequence of the death of the Prince of Wales, which disarranged the public business.

Upon a review of the history of our policy, the inference seems to be, that although the maxims prevalent in our courts of law have been generally favourable to aliens, and although the government appear to have been at all times sensible of the advantages resulting from a liberal reception of foreign settlers engaged in trade, yet popular prejudices have been on the whole successfully exerted in impressing upon the legislature a more jealous and exclusive system.

The Alien Acts (33 Geo. III. c. 4; 34 Geo. III. c. 43, 67, and others) were passed entirely from political motives, and were mainly enacted on account of the great number of foreigners who came to England in 1792 and 1793. There is reason to believe that the crown has always had the power of banishing aliens from the realm, which these acts, however, expressly gave to it: at all events, the power has undoubtedly been often exerted; and it seems almost to be included in the ampler prerogative of declaring war against the whole, or any part, of a foreign state. However, either from want of recent authentic precedents, or from a desire to accompany the measure with provisions not within the ordinary exercise of the prerogative, this power has not been exercised of late years without the sanction of parliament. In 1827 a measure was introduced (7 Geo. IV. c. 54) for the general registration of all aliens visiting this country, and every foreigner was required to present himself at the Alien office. This Act was repealed by 6 & 7 Wm. IV. c. 11, but new provisions of a similar character were introduced. Masters of vessels arriving from foreign parts are to declare what aliens (mariners navigating the vessel excepted) are on board or have landed, under a penalty, for omission or for false declaration, of 20*l*., and 10*l*. for each alien omitted. Every foreigner on landing is required immediately to exhibit any passport in his possession to the chief officer of customs at the port of debarkation, and to state to him, either verbally, or in writing, his name, birth-place, and the country he has come from, under a penalty, for neglect or refusal, of 2*l*. The officer of customs is to register this declaration, deliver a certificate to the alien, and transmit a copy of the declaration to the secretary of state. On leaving the country the alien is required to transmit to the secretary of state the certificate granted him on landing. The act does not affect foreign ministers or their servants, nor aliens under fourteen years. The proof of non-alienage lies on the person alleged to be an alien. Under the former act aliens were required to present themselves at the Alien-office; but this is no longer necessary. The registration clause, it may be added, is generally disregarded by foreigners, and is never enforced, for there is no provision in the Act for recovering the penalty. ('Blackst. Comm.,' Mr. Kerr's ed., v. i. pp. 254, 308, 367, et seq.)

The same classes of persons who are aliens according to the law of England, are aliens according to that of Scotland, and the statute law on the subject extends to that part of the empire. When an alien resident in Scotland wishes to acquire the privileges of a British subject, the same forms which, as above described, are applicable to England, are gone through with the same effect. They are consistent with the constitutional doctrine of the separate kingdom of Scotland, in which, anterior to the Union, it appears that letters of denization could give a portion, but an Act of Parliament only could communicate the whole of the privileges of a born subject of the crown. The institutional writers maintain that an alien cannot hold any kind of heritable property in Scotland, but in the books there are only two cases on the subject, and in one the general question was evaded; in the other an alien was found not to have a sufficient title to pursue a reduction of a conveyance of an estate. If the rule that aliens cannot hold heritage were strictly interpreted, it would affect property which all classes of persons are in the practice of holding in Scotland without molestation, but in the general case it would be difficult to find a form in which an alien's title could be brought in question. It is questioned whether an alien in Scotland who holds the statutory qualification may vote for a member of the House of Commons. The sheriffs, who are judges in the registration courts, have given conflicting judgments on this point.

The following are the laws as to aliens in France and the United States of North America, two countries with which Englishmen are more closely connected than any other:—

A child born in France, of foreign parents, may, within one year after he has attained the age of twenty-one, claim to be a Frenchman; if he is not then resident in France, he must declare his intention to reside there, and he must fix his residence there within one year after such declaration. An alien enjoys in France the same civil rights as those which Frenchmen enjoy in the country to which the alien belongs; but he enjoys the right of succession in France, although this right may not be granted to French citizens in his own country. An alien is allowed by the king's permission (*ordonnance du roi*) to establish his domicile in France; and so long as he continues to reside there, he enjoys all civil but not political rights; but this enjoyment ceases immediately the domicile is lost. After an uninterrupted residence during ten years, by permission of the king an alien may become naturalised. ('Code Civil,' liv. 1, tit. i. s. 9.) A foreigner can buy and hold land in France without obtaining any permission from the crown or legislature.

Upon the recognition of the independence of the United States of North America by the treaty of Paris, 1783, the natural-born subjects of the king of England who adhered to the United States became aliens in England; and it was decided that they became incapable of inheriting lands in England. It had been previously decided in America that natives of Great Britain were aliens there, and incapable of inheriting lands in the United States. Kent defines an alien to be "a person born out of the jurisdiction of the United States;" but this definition is not sufficiently strict, for the son of an alien, which son is born in the United States, is also an alien.

Congress has several times altered the law respecting naturalisation, but chiefly as to the period of previous residence. In 1790, only two years' residence was required; in 1795 the term was prolonged to five years; and in 1798, to fourteen years. In 1802, the period of five years was again adopted, and no alteration in this respect has taken place. The benefits of naturalisation have always been confined to "free white persons;" persons of mixed blood are excluded, as well as the African and other pure races, whether black or copper-coloured. At what point a person of mixed blood could claim naturalisation is doubtful. By an old law of Virginia, which was not repealed up to a recent period, a person with one-fourth of negro blood is deemed a mulatto. An alien in the United States cannot have full and secure enjoyment of freehold of land; and if he does, the inheritance escheats. He can neither vote at elections nor hold public offices. Two years at least before he can obtain the privileges of a natural-born citizen he must appear in one of certain courts, or before certain officers, and declare on oath his intention to become a citizen of the United States, and to renounce his allegiance to his own state or prince. When the two years have expired, and if the country to which the alien belongs is at peace with the United States, he is next required to prove to the court, by his oath as well as otherwise, that he has resided five years at least in the United States, and one year in the state where the court is held; and he must show that he is attached to the principles and constitution of the United States, and is of good moral character. The court then requires that he should take an oath of fidelity to the constitution, and likewise an oath by which he renounces his native allegiance. He must also renounce any title or order of nobility, if he has any. The children of persons naturalised according to this form, if they were minors at the time, are deemed citizens if they are then dwelling in the United States. If an alien dies in the interval between having taken the preliminary steps towards his naturalisation and the time of his admission, his widow and children become citizens. If an alien resided in the United States previously to the 18th of June, 1812, the preliminary notice of two years is not necessary, nor if he be a minor under twenty-one and has resided in the United States during the three years preceding his majority. In the case of an alien who has arrived in the United States after the peace of 1815, it is required that he should not at any time have left the territory during the five years preceding his admission to citizenship. A naturalised alien immediately acquires all the rights of a natural-born citizen, except eligibility to the office of President of the United States, and of governor in some of the states. A residence of seven years, after naturalisation, is necessary to qualify him to be a member of Congress. (Kent's 'Commentaries,' vol. ii. p. 50-75.)

In 1804 Congress passed an Act supplementary to the Act of 1802, which contains a clause respecting the children of American citizens born abroad, but it applies only to the children of persons who then were or had been citizens; and Kent remarks ('Commentaries,' vol. ii. p. 53) that the rights of the children of American citizens born abroad are left in a precarious state; and in the lapse of time there will soon be no statute which will be available, in which case the English common law will be the only principle applicable to the subject.

Before the adoption of the present constitution of the United States, the several states had each the privilege of conferring naturalisation. Each state can still grant local privileges. There is a considerable diversity in the laws of different states respecting aliens. By a permanent provision in the state of New York, an alien is enabled to take and hold lands in fee, and to sell, mortgage, and devise (but not to demise and lease the same), provided he has taken an oath that he is a resident of the state, and has taken the preliminary steps towards becoming a citizen of the United States. There are similar provisions in several of the other states. In New York resident aliens holding real property are liable to be enrolled in the militia, but they are not qualified to vote at any election, of being elected to any office, or of serving on a jury. In North Carolina and Vermont the constitution provides that every person of good character who comes into the state and settles, and takes an oath of allegiance, may hold land, and after one year's residence he becomes entitled to most of the privileges of a natural-born citizen. In Connecticut the superior court, on the petition of any alien who has resided in the state six months, has the power of conferring upon him the same privileges in regard to holding land, as if he were a natural-born citizen. In Pennsylvania aliens may purchase lands not exceeding 5000 acres, and hold and dispose of the same as freely as citizens. In Georgia aliens can hold land, provided they register their names in the Superior Court. No alien can act as executor or administrator in this state. In Kentucky, after a residence of two years, an alien can hold land. In Indiana, Missouri, and Maryland the disqualification of an alien holding land is done away with on his giving notice of an intention to become a citizen. Most, if not all, of the state legislatures are in the habit of granting to particular aliens, by name, the privilege of holding real property. ('Law relating to Aliens in the United States,' in 'Boston Almanac,' 1835.)

In the States generally, perhaps in all, as in England, the alienage of a woman does not bar her right of dower.

The following information is abstracted from evidence given by Harvey Gem, Esq., before the Select Committee on aliens, in 1843, and the information was stated to have been obtained from the ambassadors or ministers of the different Powers in London:—

In Prussia, from the moment when an alien becomes a resident and places himself under the protection of the laws, he enjoys the same rights as a natural-born subject, and not only has he a right to vote in the election of members to the Provincial States, but he is also eligible himself as a member.

In Saxony, by a law passed in 1834, an alien may acquire the privileges of a natural-born subject by right of domicile, granted by the local authorities of each district, or by the purchase of real property, and in towns by obtaining the freedom of the corporation. In the two latter cases, the alien must have been in possession of his real property or of his freedom for five years, during which period he must have resided in the place where the property is, or in the town of which he has obtained the freedom. The right of voting, eligibility as a representative of the Chambers of the Kingdom, &c., depend upon the nature and value of the real property acquired, whether a manor, a house in a town, &c.

In Bavaria aliens can possess landed property, without the condition of residence, but they are liable to the duties which attach to the property. Naturalisation is obtained either by marriage of a foreign woman with a Bavarian, by domicile and renouncing foreign allegiance, or by royal decree; but a residence of six years is necessary before the full citizenship can be obtained. The privileges of an alien in Bavaria depend in some degree on the policy of the state of which he is a subject towards foreigners in general or Bavarians in particular.

In Würtemberg an alien who wishes to be naturalised, first purchases landed property in or near the place where he intends to settle, by which he obtains the consent of the local authorities to reside among them (bürger-recht). These conditions having been fulfilled and the sanction of government obtained, the alien acquires the Staatsbürger-recht, which gives him all the privileges of a natural-born subject, and with them its obligations, as liability to the military conscription, &c. The burger-recht may give an alien all the municipal rights of a citizen in a town, while, as respects the Staatsbürger-recht, which makes him a citizen of the state, he may still be an alien.

In Hanover naturalisation is acquired in one or other of the following ways: by marriage of a foreign woman with a Hanoverian subject; by the adoption by a Hanoverian of a foreigner as his child; by holding any office under the government; by becoming a member of a commune; by the purchase of a residence or freehold in any commune; by the authority of the State, independently of the will of the commune; and by a residence of five consecutive years in any commune with the express approbation of the bailiff or mayor—the conditions in the two last cases being the possession of sufficient means of subsistence and an irreproachable character.

In Austria a residence of ten years is sufficient in all cases to obtain naturalisation. Whoever holds any office, either civil or military, under the crown, is thereby naturalised. Merchants or manufacturers who come to settle in the country with their families can obtain naturalisation at once, if they are of good reputation and not in needy circumstances. Naturalisation confers, without any exception, all the rights and privileges of natural-born subjects.

The Act of the German Confederation, Art. 18, gives to every German the right of holding civil and military offices in the different states of the Confederation.

In Denmark, every foreigner who settles there with the intention of remaining, and who owns land of the value of 30,000 crowns, or houses in the towns of the value of 10,000 crowns, or a capital of 20,000 crowns in trade, acquires by that alone the right of demanding letters of naturalisation. Children born in Denmark of foreign parents, and persons naturalised, are eligible to all public offices, with one exception, which is this, a naturalised foreigner does not become eligible as a deputy of the provincial States until he has resided for five years in the European dominions of Denmark, and renounced his foreign allegiance.

In the Hanseatic towns naturalisation is acquired in the following manner:—In Lübeck and its territory, any person of respectability, especially after a prolonged residence, is admitted as a citizen without difficulty, on showing, if required, that he has sufficient means of subsistence. Letters of naturalisation confer all the rights which natural-born subjects enjoy. In Hamburg an alien cannot hold landed property, but any persons taking up their bonâ-fide residence there may obtain letters of naturalisation on payment of a moderate sum (a few pounds, it is stated), upon which they enjoy all the rights of native citizens, with the exception of not being eligible to the order of the bürgerschaft; but the restrictions in this case apply only to age and some other qualifications, which are equally applicable to native citizens. No business can be transacted by foreigners until they have obtained the privilege of citizenship, and become members of some one of the guilds. Any foreigner may become a citizen by purchase. Jews cannot become citizens. In Bremen an alien obtains the rights of citizenship for a money payment, and by becoming a member of a commune. In Frankfort naturalisation is obtained by gift for public services, by marriage, or by purchase, if the person desirous of becoming a citizen can give satisfactory references as to character, station, and property.

In Sardinia the power of conferring naturalisation rests entirely with the king, and is never refused on any bonâ fide application: a naturalised person enjoys all the privileges of a natural-born subject.

In Portugal an alien of not less than twenty-five years of age can obtain letters of naturalisation after two years' residence, and provided he has the means of subsistence. The two years' residence is dispensed with if the alien has married a Portuguese woman; or has opened or improved a public road; embarked money in trade; improved any branch of arts; introduced any new trade or manufacture; or otherwise performed some service of public utility.

In Belgium an alien cannot purchase or hold land. There are two kinds of naturalisation, the petite naturalisation and the grande naturalisation. The first gives the alien some advantages, as the right to sue, &c.; and the second, which is an act of the legislature, confers political privileges, in addition.

In Switzerland naturalisation is conferred in some cantons by the legislature, and in others by the executive. In Tessin a naturalised foreigner can only enjoy the full rights of citizenship after five years have elapsed from the date of his naturalisation. In Thürgau no one can hold any office under the government unless he has been a burgess of the canton at least five years. In Berne, Zürich, Vaud, Geneva, and most of the cantons, an alien obtains the full citizenship from the date of his naturalisation.

In Russia no foreigner, who does not become a "perpetual subject," can enjoy the rights and privileges attached to the guild of merchants. The commercial rights belonging to merchants are enjoyed in their character as guests, or as itinerant merchants. A foreigner who imports goods must sell them to Russians only.

ALIMENT. [ALIMONY.]

ALIMONY, from the Latin *alimonium* or *alimonia*, signifying "maintenance," or "support." By the law of England, a wife is presumed to have surrendered the whole of her property to her husband upon marriage, and consequently to be entirely dependent upon him for her future maintenance. Upon this principle it is considered reasonable that if a separation is decreed, the wife should have a portion of her husband's estate allotted for her subsistence; and this allowance is termed in law "alimony." The right of the wife to this provision depends upon the fact whether she has or has not sufficient means, independently of her husband, to support her in her appropriate station in life. Where the wife has a sufficient income beyond the husband's control, she is not entitled to alimony.

Alimony, as incidental to questions relative to or arising from marriage, fell until recently under the exclusive cognisance of the ecclesiastical courts; but the jurisdiction of these tribunals has now been transferred to the Court for Divorce and Matrimonial Causes; which is, however, directed to act on the principles of the ecclesiastical courts in matrimonial causes. The giving of alimony is necessarily incidental to a decree of judicial separation or divorce, and may be temporary or permanent. While the proceedings in the suit are pending, the court will, generally speaking, allot alimony to the wife during the continuance of the litigation. When a decree has been obtained, a permanent provision will be given to her. In both cases it is an annual allowance proportionate to the estate of the husband.

The amount of alimony depends wholly upon the discretion of the court, equitably exercised with a view to the circumstances of each particular case. After a separation on account of the husband's misconduct, the wife is alimented as if she were living with him as his wife. The court attends carefully to the nature as well as to the amount of the husband's means, drawing a distinction between substantial property and an income derived from personal exertion. The station in life of both parties, and the fortune brought by the wife, are also considered; and much stress is laid upon the disposal of the children and the expense of educating them.

The conduct of the parties forms also a very material consideration. Where the wife has eloped from her husband, or where a sentence of divorce proceeds upon the ground of her adultery, alimony is not granted. Adultery in a wife involves a forfeiture of her dower. For the same reason the adulteress shall not partake of the husband's estate while living.

In assigning alimony, it should be observed, that during the continuance of a suit it is always much less in amount than when permanently decreed. Thus in the former case the proportion usually allowed is one-fifth of the net income of the husband; in the latter, a moiety of the whole income is not unfrequently given. No general rule can, however, be laid down upon this subject, as the amount granted must always depend upon the infinitely varied combinations of facts brought before the court.

The assignment of alimony during the continuance of a suit does not discharge the husband from liability for his wife's contracts. When the court has allotted her a permanent maintenance, the wife is liable for her own contracts, and the husband is discharged from them.

The equivalent in Scottish law for alimony, is *Aliment*. A wife is entitled to aliment when deserted by her husband, when judicially separated from him, and during a suit for a divorce whether at her own or at his instance, the aliment in this last case including what may be necessary for the expenses of the defence. She has no right to aliment in the case of a voluntary contract of separation.

ALIQUOT PART. One number or fraction is said to be an aliquot part of a second number or fraction, when the first is contained an exact number of times in the second. Thus, 6, 3, 4, 2, 1½, $\frac{3}{7}$, $\frac{1}{8}$, &c., are all aliquot parts of twelve, being contained in it respectively 2, 4, 3, 6, 8, 28, 96, &c. times. The word is principally used in the arithmetical rule called *practice*, and the convenience of using it is as follows: If we want to know how much 30½ yards cost at 1*l.* 15*s.* 6*d.* a yard, the direct process of common arithmetic would be to turn 30½ yards into half yards, giving 61, and 1*l.* 15*s.* 6*d.* into sixpences, giving 71. Then multiplying 61 by 71, and dividing the product by 2, we have the number of sixpences which 30½ yards cost, which must then be reduced into pounds, shillings, and pence. But if we observe that 1*l.* 15*s.* 6*d.* is made up of 1*l.*, 10*s.* the half of one pound, 5*s.* the half of 10*s.*, and 6*d.* the tenth of 5*s.*, we can proceed as follows:—

	£	*s.*	*d.*		£	*s.*	*d.*
30½ yards at	1	0	0	per yard, cost	30	10	0
"	0	10	0	"	15	5	0
"	0	5	0	"	7	12	6
"	0	0	6	"	0	15	3
"	1	15	6	"	54	2	9

in which each line is derived from the preceding by simple division, on the obvious principle that at 6*d.* a yard we give the tenth part of what we give at 5*s.* a yard, and so on.

The object therefore is, to be ready in dividing a sum of shillings and pence into parts, each of which shall be the aliquot part of a pound, or of one of the preceding parts. The following table contains the simple aliquot parts of a pound, arranged so that the aliquot part of an aliquot part shall be visible on inspection. Figures written by themselves are shillings, and the semicolons separate shillings from pence.

The aliquot parts omitted contain fractions of farthings, and are useless.

		Half.	Third.	Fourth.	Fifth.	Sixth.	Eighth.	Tenth.	Twelfth.	Twentieth.	Fortieth.
	£1	10	6; 8	5	4	3; 4	2; 6	2	1; 8	1	;6
Half,	10	5	3; 4	2; 6	2	1; 8	1; 3	1	;10	;6	;3
Third,	6;8	3; 4		1; 8	1;4		;10	;8		;4	;2
Fourth,	5	2; 6	1; 8	1; 3	1	;10	; 7½	;6	; 5	;3	;1½
Fifth,	4	2	1; 4	1		; 8	; 6		; 4		
Sixth,	3;4	1; 8		;10	;8		; 5	;4		;2	;1
Eighth,	2;6	1; 3	;10	; 7½	;6	; 5	; 3¾	;3	;2½	;1½	; ¾
Tenth,	2	1	; 8	; 6		; 4	; 3		;2		
Twelfth,	1;8	;10		; 5	;4		; 2½	;2		;1	; ½
Twentieth,	1	; 6	; 4	; 3		; 2	; 1½		;1		
Fortieth,	;6	; 3	; 2	; 1½		; 1	; ¾		; ½		

This table shows all the aliquot parts of a pound down to one halfpenny: for example, we see ;2½, signifying twopence-halfpenny, opposite to *twelfth* under *eighth*, which shows us that 2½ is the twelfth part of the eighth part of a pound. If, therefore, we wished to find how much 3715 yards cost at 2½*d.* a yard, instead of multiplying by 2½, and dividing by 12 and 20, we should divide by 8 and 12, as follows:—

```
 8 ) 3715
    ---------
12 ) 464  7  6
    ---------
   £38 13 11½
```

[PRACTICE.]

ALIZARIC ACID. [MADDER.]

ALIZARIN ACID. [MADDER.]

ALKALIES. Although the term *alkali* (compounded of the Arabic prefix *al*, and *kali* the name of plant-ashes, from which potash is obtained) was formerly rather loosely applied to a variety of basic substances, yet its use is now generally restricted to three metallic oxides, namely, potash (KO), soda (NaO), and lithia (LiO), which from their non-volatility at a red heat are termed the *fixed* alkalies, and to ammonia, a compound of nitrogen, hydrogen, and oxygen (NH_4O), which on account of its volatility, even at ordinary temperatures, is sometimes called the *volatile* alkali.

The chemical properties of the alkalies are the following: their aqueous solutions turn vegetable blues green, and vegetable yellows reddish-brown; hence infusion of red cabbage and infusion of turmeric, or papers stained with them, are used as tests of the presence of an alkali. The alkalies restore the colour of vegetable blues—as of litmus, for instance—which have been reddened by acids, and, on the other hand, the acids restore vegetable colours which have been altered by the alkalies. These properties are also common to lime, baryta, and strontia.

The alkalies have great affinity for, and readily combine with, acids, forming *salts*, and the power of both in altering vegetable colours, is then destroyed. The alkalies are separated at the negative pole of the voltaic decomposition cell.

Potash and soda destroy the skin when applied to it in concentrated solution. These alkalies, together with lithia, are inodorous, but possess a peculiar acrid taste. Ammonia has a similar taste, and possesses a very pungent odour, like *hartshorn*, or *smelling salts*. All the alkalies are very soluble in water. For their preparation, special properties, and uses, see POTASH, SODA, LITHIA, and AMMONIA.

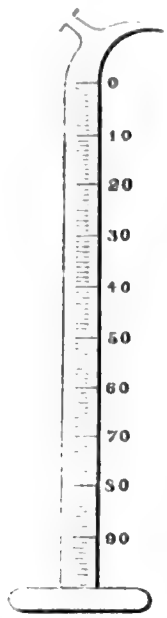
ALKALIES, *Medical Properties of.* It is impossible to exclude magnesia and lime from consideration when treating of alkalies, but the remarks which follow are chiefly intended to apply to soda, potassa, and ammonia. The two former are termed *fixed*, the latter *volatile*: soda is likewise termed the *mineral* or *fossil* alkali; while potassa is termed the *vegetable* alkali, or sometimes merely *kali*. The salts formed with alkalies are apt to *effloresce*, and resolve the crystals into the state of powder, or to absorb water from the air, and *deliquesce* or become liquid.

Alkalies in a pure state are extremely caustic, destroying the tissues with which they come in contact, and forming an eschar which is deep if the alkali be confined, extensive and superficial if allowed to spread. This seems to depend on their strong affinity for water: hence they act as violent corrosive poisons, and are never used in a pure state, save in surgery to open abscesses or to form caustic issues. Diluted with oils they constitute rubefacients, particularly ammonia. Their causticity is also greatly lessened by combination with carbonic acid, and is more subdued by an excess of the acid; hence bi-carbonates are less caustic than sesqui-carbonates, and these last than carbonates. Carbonate of ammonia will altogether disappear if not kept in a well stopped bottle; this tendency is one source of its utility when used as smelling salts.

When suitably diluted with water or by combination with carbonic acid, so as to be safely applied to the tongue, alkalies have a taste peculiar, and to most persons unpleasant, which is designated *alkaline*, for want of anything similar to which to liken it. Ammonia and its carbonates are likewise pungent. They exercise an immediate influence on the fluids of the mouth and alimentary canal, as far as they pass unchanged. They neutralise all acids they meet with in their course, and render the mucus, and perhaps some other secretions, thinner and more watery. That they are readily absorbed into the circulating mass, on which they have a marked influence, is certain; but they are for the most part speedily eliminated, the kidneys appearing to be the channels by which they are thrown out of the system. Many alkaline compounds, as well as the uncombined but diluted alkalies, increase the secretion of urine, and change its nature, if long persevered in, altering it from an acid to an alkaline state. This is particularly the case when the compound is one of carbonic acid, or of a *vegetable* acid with the base, all of which are decomposed *in transitu*, as first remarked by Sir Gilbert Blane, and produce on the urine, and the system generally, ultimately the same effects as the pure alkalies. The alkalies possess a power of rendering albumen soluble: unboiled white of egg is an albuminate of soda. The albumen of the blood is rendered more fluid by alkalies; hence in excess they impair the plastic power of that fluid.

These facts seem all that are requisite to form a correct estimate of their therapeutic powers and employment. Their caustic and rubefacient properties fit them for external use. Their internal employment is regulated by a variety of indications, but it is chiefly as antacids, or to counteract acidity in the stomach and *primæ viæ*, and as diuretics, and to dissolve *calculi* in the kidneys or bladder, and as refrigerant or cooling medicines in inflammatory diseases, that they are used. Many persons, soon after food has been taken into the stomach, are distressed with heartburn and other signs of indigestion, and either have the urinary secretion in an unhealthy state, or, if they be of a gouty disposition, have frequent attacks of gout. Such persons feel relief by taking some alkaline medicine after meals, or have recourse to them because others use them. When uric or lithic acid exists in the urine, such means may be proper; but this point should be ascertained before having recourse to measures which, when not appropriate, are far from being harmless. Some acid, either hydrochloric or acetic, is essential to sound digestion: to neutralise these is to retard and disturb that process. Other acids, especially lactic, in bilious persons and those who use sugar or saccharine fruits in excess, occur, and require to be obviated; but the proper time for taking, as well as the proper quantity to be taken, requires much judgment. Assuming that some alkali is proper, Sir B. Brodie thinks from three to four hours after each of the principal meals, especially dinner, the most suitable time. ('Lectures on the Urinary Organs,' 3rd ed. p. 203; and 'Medical Gazette,' vol. xxiii. p. 151.) Dr. Prout makes a similar remark with respect to alkaline mineral waters. A variety of circumstances regulate the alkali to be selected. From their greater causticity, the pure alkalies can rarely be persevered in sufficiently long, even when taken in such bland vehicles as veal-broth. The alkaline carbonates are better borne, and bi-carbonate of potass more easily than carbonate of soda. Their unpleasant taste constitutes an objection with many: this is in some degree obviated by giving them in the condensed form recently devised by Mr. Brockedon, or in an effervescing state with an excess of alkali, as recommended by Sir Gilbert Blane. If taken unnecessarily or persevered in too long, much evil is done: not only is an alkaline state of urine induced, with a deposition of the phosphates, as indicated by a white sabulous sediment, or an iridescent pellicle on the surface of the urine, but much general debility is caused. "Other ill consequences follow the too liberal use of alkalies: they alter the quality of the blood. After some time the patient is liable to petechiæ; he perspires too easily, becomes low-spirited, and less capable than when in health of physical exertion." (Brodie, *l. c.* p. 202.) As effervescing or saline draughts, made with a *vegetable* acid and some alkaline carbonate, are much used at the beginning of inflammatory diseases for their reducing and refrigerant effects, the same caution is requisite lest they be pushed too far. This is also needful in the case of soda-water (when it really contains soda, and not merely carbonic acid, as is frequently the case), citrated alkali, imperial, and other drinks much used in warm weather. Scrofulous persons can least of all bear up against the abuse of these, yet for such are they unfortunately most employed. Weak vegetable acids will be found more beneficial.

ALKALIMETRY, a term applied to certain ready methods of estimating the commercial value of the alkalies, more especially of potash and soda, and of certain of their salts which possess an alkaline reaction. The most simple method of performing this operation consists in ascertaining the amount of a dilute acid of known strength required exactly to neutralise 100 grains of the sample of alkali. The alkalies and alkaline salts generally tested in this way are potash, soda, and their carbonates. For most of the purposes to which these materials are applied in the arts, their value depends upon the quantity of the alkali which they contain, either in a caustic state or in the condition of carbonate; other alkaline salts or compounds that may be present being useless, if not deleterious. As soda is much more largely used in the arts than potash, the standard acid, or *test acid*, as it is termed, is often made with reference to this alkali, and is graduated to such a strength that 1000 grain measures of it exactly neutralise 100 grains of anhydrous caustic soda (NaO); but the following method of preparing the test-acid, recommended by Faraday, is the most convenient and generally applicable, both to potash, soda, and their carbonates. The test-acid employed is measured from an instrument termed an *alkalimeter*, which consists of a glass tube supported upon a foot, and graduated into 100 equal parts, the space between every two of such divisions being capable of containing 10 grains of distilled water. The upper part of the instrument is shaped as shown in the figure, for the convenient introduction of the test-acid and its subsequent delivery in drops.



The dilute sulphuric acid, or test-acid, is prepared by adding eight volumes of distilled water to one volume of concentrated sulphuric acid. After cooling, this mixture ought to have a specific gravity of 1·1268. In order to ascertain that it is of the exact strength, 100 grains of pure and dry carbonate of potash are to be dissolved in about 4 ounces of boiling water, and the solution tinged blue by the addition of a few drops of infusion of litmus. The alkalimeter must now be filled up to the 65th division with the dilute acid, and afterwards with water to the point of the scale marked 0. The two liquids being then thoroughly mixed by agitation, the contents of the alkalimeter must be gradually added to the hot solution of carbonate of potash until the blue colour changes to red, indicating that the acid is then in slight excess. If the acid be of the proper strength, exactly 100 measures, or the total contents of the alkalimeter, ought exactly to produce this effect, showing that each measure of the acid is equivalent to one grain of carbonate of potash. If less than 100 measures have been required, the acid is too strong; if more than 100 measures, it is too weak. Let us suppose that 90 measures produced the reddening effect: it is evident that in this case the 90 measures are equivalent to 100 grains of carbonate of potash, and consequently the acid is $\frac{1}{9}$th too strong; each 90 measures of the original test-acid must therefore be diluted with 10 measures of water. If the acid were too weak, a similar but inverse correction must be had recourse to. The test-acid having been thus prepared of the proper strength, it must be preserved in well-stoppered bottles for subsequent use.

To employ it for estimating the amount of carbonate of potash in any sample of pearlash, weigh out 100 grains of the ash, dissolve them in boiling water as above described, filtering if necessary, and tinge blue with infusion of litmus; then fill the alkalimeter to 65 with the test-acid, diluting with water to 0°, and add the diluted acid gradually and cautiously until the reddening effect is produced. The number of measures of acid required represents the percentage of carbonate of potash in the sample.

To estimate the amount of potash contained in the sample, either as caustic potash or carbonate of potash, fill the alkalimeter to 49 with the test-acid, the 100 measures being again made up with water. The number of divisions of this dilute acid required to neutralise 100 grains of the sample will correspond to the percentage of pure potash in the sample.

For the determination of carbonate of soda, the alkalimeter must be filled to 54·6 with the test-acid, which must then be used as before; whilst for the estimation of caustic soda, the operator will require to fill the instrument to 23·4. The number of measures required to change the blue of the solution to red, will then in both cases correspond to the percentages of caustic or carbonated alkali required. Care must be taken in all cases to have the alkaline solution nearly at the boiling point when the test-acid is added, and also not to confound the port wine red produced by carbonic acid with the bright red resulting from the slightest excess of sulphuric acid; the latter tint is of course the one which indicates that the neutralisation has been completed.

It is obvious that the foregoing method might also be employed for testing the strength of ammonia and its carbonate.

Fresenius and Will propose to ascertain the value of samples of the carbonates of the alkalies by ascertaining the weight of carbonic acid expelled on neutralising them with sulphuric acid, but the process is more troublesome than the one just mentioned, and as it has not been adopted in this country, it need not be here described. For a description of it, see Miller's 'Elements of Chemistry,' vol. ii. p. 740.

ALKALOIDS. [ORGANIC BASES.]

ALKALOIDS, *Medical Properties of.* These substances, which modern chemistry has made known, are termed *organic* alkalies, from requiring, in general, a vital power to effect their formation; *urea* is an exception. They possess alkaline properties in the lowest degree, and are either tasteless or have a bitter acrid taste, existing generally in a solid, mostly crystalline, form; some however are amorphous (Aconitina), occasionally in a liquid state (Conia and Nicotina), the latter very volatile, and readily undergoing decomposition, with an evolution of ammonia, at a moderate temperature. Sometimes one only exists in a plant, sometimes several in the same plant, *ex.* opium. Generally they are combined with an acid; most frequently it is a peculiar acid. Many of them are with difficulty soluble in water, more so in alcohol; they rarely completely neutralise acids, but the salts which they form are more soluble than the bases; hence various of their salts are used in medicine in preference to the primitive article. Their great characteristic is the extraordinary action most of them have on the human system in a very small dose, and indeed several of them are, in very minute quantity, deadly poisons. Having been first detected in plants long used as medicines (Cinchona), it is chiefly among medicinal plants that they have been sought for and found. By many they are regarded as the active principle of these, and their extraction has had the great advantage of enabling medical men to administer their remedies in a smaller bulk and more convenient form. As the most important of them are treated of under the names of the plants which yield them, it is not necessary to notice any of them further here, except to state that chemists have recently rendered a great service in forming a neutral sulphate of quinine, which is much more soluble than the disulphate, and called Bullock's Neutral Sulphate of Quinine.

ALKARSIN. [CACODYL.]

ALKERMES is the name of a cordial made in some of the northern countries of Europe. It is made from bay-leaves, mace, nutmegs, cinnamon, cloves, brandy, syrup of kermes, and orange-flower water. The first six ingredients are distilled, and the last two are employed to give flavour.

ALLA-BREVE, in music, an Italian term signifying a quick time, in which the notes take only half their usual length. It is very rarely used in modern music. The fine fugue in the 'Messiah,' 'And with his stripes we are healed,' is an example of this measure.

ALLAH is the Arabic name of the Supreme Being, which through the Koran has found its way into the language of all nations who have embraced the Mohammedan religion. It is properly a contraction of al-ilâh: al is the Arabic definite article, and ilâh, which corresponds to the Hebrew words Eloah and Elohim, signifies a deity generally: the prefixed article restricts the meaning, and al-ilâh or Allah signifies the True God, as opposed to the deities worshipped by idolaters. The word Allah is frequently met with as a component part of Arabic proper names: for example, 'Abd-allah,' that is, 'the servant of God.' 'Allah akbar,' 'God is great,' is the common battle-cry of the Mohammedans. The phrase 'Bism Allah' or 'Bism-illah,' 'in the name of God,' is invariably uttered by devout Mussulmans before the commencement of any undertaking, and before their meals: it is also put at the beginning of their books.

ALLANTOIN. [URIC ACID, DERIVATIVES OF.]

ALLANTURIC ACID. [URIC ACID, DERIVATIVES OF.]

ALLEGATION, ECCLESIASTICAL, was the term applied to the first pleading in testamentary causes in the Courts Christian, whose jurisdiction in these matters is now transferred to the Court of Probate. In criminal proceedings the first plea is called *Articles*; in ordinary causes the first plea is called the *Libel*. This first pleading in each instance is analogous to a Declaration at common law or to a Bill in equity. The term Allegation is also applied to every subsequent plea in all causes; the first by a defendant being called a Responsive Allegation, and the plaintiff's answer a Counter Allegation. There are also exceptive allegations, when a witness's credit is impeached, and these, when admitted, are proceeded upon in the same manner as the others.

ALLEGIANCE, or LIGEANCE, is the true and faithful obedience of a liegeman or subject to his liege lord or sovereign, "Ligeantia est vinculum fidei: ligeantia est legis essentia." The notion of ligeance, or allegiance, is that of a bond or tie between the person who owes it and the person to whom it is due. (Co. Lit. 129 a.) Allegiance is due from natural-born subjects, and also from those who have been naturalised.

The allegiance of a subject, according to the law of England, is permanent and universal. He can, by no act of his own—as by being naturalised in a foreign country—repudiate the duties which it involves; nor can he by any change of residence escape its legal consequences.

An alien owes a temporary allegiance so long as he continues within the dominions of the Queen; and he may, therefore, be prosecuted for treason.

An usurper, in the undisturbed possession of the crown, is entitled to allegiance. Treason committed against Henry VI. was punished in the reign of his successor, even after parliament had declared the former an usurper.

An oath of allegiance has, from the earliest period, been exacted from natural-born subjects; but its form has undergone variation. Anciently, the party promised "to be true and faithful to the king and his heirs, and truth and faith to bear of life and limb and terrene honour, and not to know or hear of any ill or damage intended him without defending him therefrom." The statutory oath, since the Revolution, has been more simple—as: "I do sincerely promise and swear that I will be faithful and bear true allegiance to her Majesty Queen Victoria." By the statute 21 & 22 Vict. c. 48, these words are preserved in the *one* oath thereby substituted for the oaths of allegiance, supremacy, and abjuration, formerly used.

The alteration of the form has never, in any degree, varied the nature of the subject's duty, which is owing from him independently of any oath, and although he may never have been called upon to take it. The oath is imposed by way of additional security for the performance of services inherently due from the subject from his birth, who is, in like manner, entitled to the protection of the sovereign before the latter has formally accepted the duties of sovereignty by taking the coronation oath. The Crown can, by proclamation, summon the liegemen to return to the kingdom. An instance of this occurred in 1807, when it was declared, by proclamation, that the kingdom was menaced and endangered; all seamen and seafaring men who were natural-born subjects were recalled from foreign service, and ordered to return home, on pain of being proceeded against for a contempt.

By the ancient law every male subject of the age of twelve years (with certain exceptions) was bound to take the oath of allegiance when summoned to the Courts Leets and Tourns; and various statutes, from the reign of Elizabeth to the present time, expressly require it from public functionaries and other persons before they enter upon their respective duties, or practise in their several professions. By 1 George I. c. 13, two justices of the peace, or other commissioners appointed by the Crown, may tender the oath to any person suspected of disaffection.

From a violation of allegiance results the highest offence known to the law—TREASON.

(Blackst. *Comm.*, Mr. Kerr's ed. vol. i. p. 367, et seq.; Hale's *Pleas of the Crown*, vol. i. p. 58, et seq.; and Mr. Justice Foster's *Discourse on High Treason*.)

ALLEGORY, literally, a discourse which has another meaning than what is directly expressed. Thus, the address of Menenius Agrippa to his fellow-citizens of Rome, as recorded by Livy, in which he described a rebellion of the industrious against the wealthier orders of a state, under the figure of a conspiracy of all the other members of the human body against the stomach, was an allegory. An allegory, however, is not intended to deceive or perplex, in which respect it differs from an enigma or riddle.

Allegory has been a favourite mode of composition in all countries and ages. Sometimes it has been recommended by seeming to afford the only or the fittest available means of giving a lively or intelligible representation of certain subjects or notions. The poets of different nations, for example, have resorted to this method, in order to convey sufficiently vivid conceptions of the different virtues and vices, and other abstractions which they have wished to set before their readers. They have personified these notions, as it is termed; that is to say, they have figured them in the shape of living beings invested with the forms and qualities naturally adapted to the character of each. Such pictures are allegories, and are to be found abundantly scattered over nearly all poetry.

Of all poets who have dealt in allegories of this description, our own Spenser is the most famous and the greatest; no other has either produced so vast a number of these vivified idealities, or put into them such a spirit of life and air of actual existence. A long allegory, it is commonly said, has been usually unsuccessful as such; and, in illustration of this assertion, the instance of the 'Faerie Queen' has been often quoted, as that of a work which, with all its attractions in parts, is wearisome as a whole. The plan of the general allegory upon which Spenser's poem is framed, is certainly in a remarkable degree complicated, cumbersome, and uninteresting; and, if he had aimed at composing a mere tale of romance, without fettering himself with any scheme of allusion either to the moral virtues or the achievements of Queen Elizabeth, both of which subjects he has endeavoured to illustrate, he would have doubtless done better, as well as saved himself much needless labour. But, on the other hand, nobody complains of fatigue in reading Swift's 'Tale of a Tub,' which is likewise a tolerably long allegory; and Bunyan's 'Pilgrim's Progress' has always been a popular work. These, and other examples which might be quoted, seem to prove that, if the allegory be sufficiently simple and natural, it may be protracted to a considerable extent without becoming tiresome.

ALLEGRET'TO, in music, an Italian diminutive of *Allegro*, neither so fast nor so brilliant as that term denotes, though rather quick, and moderately gay.

ALLE'GRO, in Music, signifies *gay, sportive*, and, by inference, quick in time. An allegro is not understood to be so fast in vocal as in instrumental music. Its quickness is likewise modified by the number and value of the notes in a bar. Thus it is always more rapid, *cæteris paribus*, in two-crotchet time than in four-crotchet—in three-quaver time than in six-quaver; and as the speed of this movement has many degrees of difference, other words are commonly added, more exactly to explain the composer's intention. This term is also used substantively; thus, we say, an *Allegro* of Mozart, of Beethoven, &c. It is often combined with other terms, such as 'agitato,' 'brillante,' &c., to denote varieties of quickness and effect.

ALLEMANDE, in music, a dance supposed to have derived its name from the country, Germany, in which it originated. It is written in two-crotchet time, and is now understood to be moderately quick; but anciently it was a slow dance. Handel, and other composers of his period, wrote it in four-crotchet time.

ALL-HALLOWS, ALL-HALLOWMAS, or simply **HALLOWMAS**, the old English name for *All Saints' Day*, or the 1st of November.

All-Hallowmas derives its importance from the popular usages, which in our own and various other countries have distinguished sometimes the day itself, but more generally the night preceding, called its Eve or Vigil. There is reason to believe that this was a pagan before it was transformed into a Christian festival; and there can at any rate be no question that the ceremonies to which we refer are of Druidical origin. Bonfires, bell-ringings, and domestic merry-makings, in which lamb's wool (ale or wine mixed with the pulp of roasted apples) was the principal beverage, marked the eve of Hallowmas. The season called for such demonstrations. The harvest was over; the winter was at hand.

But the eve of All-Hallows is especially famous for those observances which have been wont to take place on it, connected with the superstitious wish of prying into futurity. The same ceremonies of this description appear to have been anciently practised in England, Ireland, and Scotland; but they are now almost universally disused. The well-known poem of Burns, the 'Halloween,' will immortalise the memory of the ancient ceremonies to which it relates.

ALLIANCE, THE HOLY. [TREATIES, CHRONOLOGICAL TABLE OF.]

ALLIGATION, derived from the Latin *ad* and *ligare*, signifying to bind together, or unite. It is a rule in arithmetic, by which the price of a mixture is found when the price of the ingredients is known. This is an application to commercial arithmetic only, but the following questions, which fall under the rule, will show its scope better than any general definition.

How much wine at 60*s*. a dozen must be added to a pipe worth 95*s*. a dozen, in order that the mixture may be worth 70*s*. a dozen?

If a cubic foot of copper weighs 8788 ounces, and of zinc 7200 ounces, in what proportions must copper and zinc be mixed, so that a cubic foot of the mixture may weigh 8000 ounces?

For the algebraist we may say, that all questions fall under the rule of alligation which involve the solution of such an equation as,

$$ax + by + cz = n\,(x + y + z)$$

in which n must be intermediate between a, b, and c; which is indeterminate unless further relations between x, y, and z are given. Any person moderately skilled in algebra may reduce a question of alligation to an equation of this form; and as the number of cases is infinite, and several of those given in the books of arithmetic are practically useless, we shall here confine ourselves to an example of one process for the algebraical student, and two rules of the most simple cases for all other readers.

There are three ingredients, worth a, b, and c shillings per ounce: in what proportions must a mixture of m ounces be made, so as to be worth k shillings an ounce; it being understood that the quantities of the two first ingredients must be in the proportion of p to q? Let px be the quantity of the first ingredient; then qx is that of the second; let y be that of the third. Then by the question,

$$px + qx + y = m. \quad . \quad . \quad . \quad (1)$$

But px ounces, at a shillings an ounce, cost apx shillings; therefore the price of the whole is

$$apx + bqx + cy \text{ shillings},$$

which by the question is km shillings: hence,

$$apx + bqx + cy = km. \quad . \quad . \quad . \quad (2)$$

and which two equations, with two unknown quantities, can be solved by the common method.

Rule I. Where the quantity of each ingredient, and its price, are given, to find the price per pound, gallon, or whatever it may be, of the mixture; multiply the quantity of each ingredient by its price, and add; then divide the sum of all these products by the sum of all the quantities in the ingredients.

Example. What is the worth per ounce of a mixture of 25 ounces of sugar at 10*d*. with 15 ounces at 11*d*.?

25 ounces at 10*d*. is worth 250*d*.
15 „ 11*d*. „ 165*d*.
—
40 40) 415 ($10\frac{15}{40}$*d*.
40
—
15

Answer, $10\frac{15}{40}$*d*. or $10\frac{1}{4}$*d*. very nearly.

Rule II. To find in what proportions per cent. two ingredients must be mixed, in order that the price per ounce, &c., of the mixture may be one which has been previously determined upon. To find the proportion of the *first* ingredient, take the difference of price between the mixture and the *second* ingredient, multiply by 100, and divide by the difference between the prices of the ingredients.

Example. I wish to know in what proportion wines at 45*s*. and 70*s*. a dozen must be mixed, in order that the mixture may be worth 55*s*. a dozen?

Price of the mixture . . 55*s*.
„ second ingredient 70*s*.
—
difference 15
multiply 100
—
difference of price of ingredients 25) 1500 (60
150
—
0

There must, therefore, be 60 per cent. of the first, and consequently 40 per cent. of the second.

Instead of finding the proportions per cent., the proportion in which any other number must be divided, may be found by using that number of dozen, &c., instead of 100, and the three prices may be *all* multiplied by any number which will clear them of fractions.

Example. How must 80 gallons, worth $6\frac{1}{2}d.$ a gallon, be made of ingredients worth $1\frac{3}{4}d.$ and $11d.$ per gallon?

Price of mixture.	Price of first ingredient.	Price of second ingredient.
$6\frac{1}{2}$	$1\frac{3}{4}$	11
4	4	4
26	7	44

difference of 26 and 44   18
80

difference of 7 and 44   37) 1440 ($38\frac{34}{37}$
111
330
296
34

Answer, $38\frac{34}{37}$ gallons of the first, and $41\frac{3}{37}$ of the second.

ALLITERATION. This term is usually employed to signify the juxtaposition, or frequent recurrence in composition, of words commencing with the same letter, when introduced with a view to its rhetorical effect. Byron's line in the concluding stanza of the second canto of 'Childe Harold,'

> "*W*hat is the *w*orst of *w*oes that *w*ait on age,"

may be given as an example; and another instance occurs in the same stanza, in the line

> "O'er *h*earts *d*ivided, and o'er *h*opes *d*estroyed."

Churchill has at once ridiculed and exemplified the figure in his well known verse

> "And apt alliteration's artful aid,"

where every word begins with the same letter. Modern critics have detected numerous instances of alliteration both in the Latin and Greek poets. (See the dialogue entitled 'Actius,' in the 'Latin Dialogues' of Joannes Jovianus Pontanus; and Harris's 'Philological Enquiries,' part ii. chap. iv.) Alliteration, however, has been most systematically used as an ornament of diction in the Celtic and Gothic dialects. Gerald Barry, commonly called Giraldus Cambrensis, who lived in the twelfth century, tells us, in his 'Description of Wales,' that in his day, both the English and Welsh were so fond of this figure of speech which he calls *Annomination*, that they deemed no composition to be elegant, or other than rude and barbarous, in which it was not plentifully employed. The same tendency is also said to have formed a striking peculiarity in the genius of the Irish language. (See Warton's 'History of English Poetry,' vol. ii. p. 106, note d, ed. of 1840.) Dr. Percy, in an essay published in his 'Reliques of Ancient English Poetry,' has traced the origin and history of alliterative verse down from the compositions of the old Icelandic poets. Nearly all the varieties of Runic verse, which were very numerous, appear to have depended for their prosodial character entirely upon alliteration. It was necessary that so many words in every line should begin with the same letter; and this was all that was required to make good metre. According to the learned Wormius, there were no fewer than 136 kinds of Icelandic verse formed upon this principle, and without including rhyme, or a correspondence of final syllables. If we may trust the following curious statement, given in a note by Mr. Park to Warton's 'History of English Poetry' (vol. ii. p. 106, ed. 1840), the harmonies of alliterative verse were sometimes of the most complicated description, and such as were likely, one would suppose, to elude any except the nicest and most practised ears:—"An objection has been taken to the antiquity of the Welsh poetry, from its supposed want of alliteration. But this is not the case: for the alliteration has not been perceived by those ignorant of its construction, which is to make it in the middle of words, and not at the beginning, as in this instance:

> Yn ias ir ei naws eirian.

This information was imparted to Mr. Douce, by the ingenious Edward Williams, the Welsh bard."

Of Anglo-Saxon poetry, alliteration is the most distinctive characteristic; though somewhat curiously, Mr. Tyrwhitt, in his essay on the 'Language and Versification of Chaucer,' has gone so far as to say, "For my own part, I confess myself unable to discover any material distinction of the Saxon poetry from prose, except a greater pomp of diction, and a more stately kind of march." In fact, in all Anglo-Saxon verse the alliteration is very decided, but it is especially so in narrative poetry. In the first line of every couplet there are two principal words beginning with the same letter, and this letter is the initial letter of the first emphatic word, or that on which a stress is laid in pronunciation, in the second line. The two letters in the first line are, by some authorities, called the sub-letters, the single letter in the second line the chief letter. Occasionally there is only one subletter in the first; and there is never more than one chief letter in the second line. The subject of Anglo-Saxon alliteration is fully treated by Rask, in his Anglo-Saxon Grammar, p. 136, &c.; and by Mr. T. Wright, in his 'Biographia Britannica Literaria,' p. 7, &c.; see also Conybeare's Introductory Essay to 'Illustrations of Anglo-Saxon Poetry.' The following lines from the poem of Béowulf (Kemble's ed., lines 637, &c.) will sufficiently illustrate the Anglo-Saxon form of alliteration:—

> "*S*træt wæs *s*tán-fáh
> *s*tíg wisode
> *g*umum æt-*g*ædere;
> *g*uð-byrne scán,
> *h*eard, *h*ond-locen;
> *h*ring-íren scír," &c.

The Anglo-Norman versifiers introduced rhyme into English poetry; but the popular ear retained its liking for alliteration, and rhyme and alliteration became freely intermingled—the alliteration being most used in addressing a vulgar audience. The most famous poem in the English language, entirely composed in alliterative metre, is that entitled 'The Vision of Piers Ploughman,' written about the middle of the 14th century, and attributed to William or Robert Longland, a secular priest, and a fellow of Oriel College, Oxford. This is a long work, consisting of twenty-one parts or books, and composed throughout in verses, the cadence of which appears to be generally anapæstic, but which are evidently designed to derive their chief metrical beauty from a certain artificial disposition, in each, of the words beginning with the same letter. The poem has been frequently printed. An excellent edition was published in 1856, by Thomas Wright, M.A., who, in his Introduction, says of it, that along with the alliteration it accurately preserves the other characteristic of the metre of Anglo-Saxon verse, namely that of "having two rises and two falls of the voice in each line . . . . making allowance for the change of the slow and impressive pronunciation of the Anglo-Saxon for the quicker pronunciation of Middle English, which therefore required a greater number of syllables to fill up the same space of time." The opening lines of 'The Vision of Piers Ploughman' will enable the reader to perceive these peculiarities:—

> "In a somer season
> Whan softe was the sonne,
> I shoop me into shroudes
> As I a sheep weere,
> In habit as an heremite
> Unholy of werkes,
> Wente wide in this world
> Wondres to here;" &c.

Dr. Percy, in the essay above referred to, has shown that poems continued to be written in English, the verse of which was merely alliterative, or in which, at least, alliteration served as the substitute for rhyme, down to the commencement of the 16th century, and in the Scottish dialect even to a later period. One of the compositions of this description which he cites is entitled 'Scottish Field,' and is a narrative of the battle of Flodden, which was fought in 1513. Another is a Scottish poem composed by Dunbar, who lived till about the middle of the 16th century. It is preserved in the Maitland Manuscript, and has since been published by Pinkerton. The practice of alliterative verse, as Percy has remarked, seems to have been longest preserved in the north. In the 'Canterbury Tales,' Chaucer makes his Parson, when asked for his story, reply, with a sneer at this antiquated habit of the northern versifiers of that day,

> "——— Trusteth well I am a Southern man;
> I cannot *geste, rom, ram, ruff, by my letter*,
> And, God wot, rhyme hold I but little better;
> And therefore, if you list, I woll not glose;
> I woll you tell a little tale in prose."

So strongly had alliteration obtained possession of the English ear, that even for some time after the introduction of rhyme, it appears to have been still considered an important embellishment of verse. Some fragments of our old poetry exhibit both the consonance of final syllables, and a rigid observance of all the regularities of alliteration. Even after the latter came to be neglected as a systematic accessory, it was still lavishly employed as an occasional ornament. Our popular ballad and lyrical poetry is full of such lines as those with which the Scotch song commences:—

> "*M*erry may the maid be
> That *m*arries the *m*iller;
> *F*or *f*oul day and *f*air day," &c. &c.

Down even to the present day, the use of alliteration, to a considerable extent, has continued to characterise English versification in its most polished form, and in the hands of some of our greatest poets.

Nor has the employment of this artifice of style been confined to compositions in verse. In the early part of the 17th century it was carried to a greater excess by some of our prose writers than it ever had been by our poets; grave discourses being elaborated, in which nearly all the words of each separate sentence commenced with the same letter. The longer this torture of the unfortunate sound could be protracted, the greater was deemed to be the feat of eloquence.

Those who recognise rhyme, or what Milton calls "the jingling sound of like endings," as one of the legitimate adjuncts of poetry, can hardly repudiate alliteration, which, after the same fashion, may be termed "the jingle of like beginnings." There can be no doubt that the latter artifice, judiciously employed, may be made to communicate a portion, at least, of the same sort of gratification which is conveyed by the former. The general principle upon which the pleasure we experience in both cases depends, is the similarity in dissimilarity, as it has been called, or variety combined with regularity, which is the occasion of so many of our intellectual, and of some also of our moral pleasures. Of course, the degree in which alliteration is employed, as an ornament of style, ought to be regulated by its importance, as compared with other rhetorical decorations, and by its appropriateness to the subject and the general character of the composition. Being a mere artifice of diction, it can in no case be compared with the higher beauties of thought and expression, and should never be obtruded so as to interfere with them. It sometimes serves, however, to help in what may be called the setting of a brilliant thought; and, if it have the air of coming naturally, will frequently add to the effect of an otherwise happy phrase. Its aptitude to catch the popular ear is proved by its almost universal adoption in proverbs, traditional rhymes, and other brief sayings of wit or wisdom, which their mere natural vitality has kept alive without the aid of letters, and even in a vast number of those idiomatic expressions which form the sinew and chief strength of our language. Mr. Price, the learned editor of the last edition of Warton, announced a volume which was to contain, among other matters, an essay upon alliterative metre, together with the 'Aunter of Sir Gawaine,' a romance in alliterative metre, from a MS. of the 14th century; but the work was never completed in consequence of his premature death.

ALLITURIC ACID. [URIC ACID, DERIVATIVES OF.]

ALLO'DIUM, or ALO'DIUM, is property held in absolute dominion, without rendering any service, fealty, or other consideration whatsoever to a superior. It is opposed to Feodum or Fief [FEUDAL SYSTEM], which means property the use of which was bestowed by the proprietor upon another, on condition that the person to whom the gift was made should perform certain services to the giver, upon failure of which, or upon the determination of the period to which the gift was confined, the property reverted to the original possessor. Hence arose the mutual relation of lord and vassal.

It is the general opinion that the lands which the Germanic tribes, Franks, Burgundians, and Visigoths, seized during the decline of the Roman empire, were distributed among the members of these tribes in some way, and held free from all service or duty. Land so held was called Allod, or Alod, and in the Latinised form, Allodium. The system of fiefs, or the feudal system, as it is called, was posterior to that of this allodial holding of lands; and it was not completely established, at least in France, till towards the end of the 10th century.

In England there is no allodial land, for all land is held mediately or immediately of the king. The name for the most absolute dominion over property of this nature is a fee (feodum), or an estate in fee, a word which implies a feudal relation. When a man possessed of an estate in fee dies without heirs, and without having devised his property, the estate escheats, or falls back to the lord of whom it was holden: or, where there is no intermediate lord, to the king as lord paramount.

The Latinised forms of this word are various:—alodis, alodus, alodium, alaudum, and others. The French forms are—aleu, aleu franc, or frank aleu, franc-alond, franc-aloy, and franc-aleuf. In many old charters alodum is explained by hereditas, or heritable estate. But it is very difficult to collect any theory from the numerous passages in which the word occurs which shall satisfactorily explain its etymology. (Du Cange, 'Gloss.' Alodis; Spelman, 'Glossarium.')

There is a very elaborate article on allodial land in the 'Staats-Lexicon' of Rotteck and Welcker, under the head 'Alodium;' and there are some remarks by Guizot, 'Histoire de la Civilization en France,' vol. iii.

ALLOPHANIC ACID ($HO, C_4N_2H_3O_5$). This acid is unknown in the hydrated or separate state. It forms crystallisable salts with baryta, potash, and soda. It is produced by the action of hydrated cyanic acid on alcohol. The water of the alcohol unites with the cyanic acid and forms the new compound which combines with the oxide of ethyl and forms an allophanate of the oxide of ethyl.

$$\underbrace{2(HO, C_2NO)}_{\text{Cyanic Acid.}} + \underbrace{C_4H_6O_2}_{\text{Alcohol.}} = \underbrace{C_4H_5O, C_4N_2H_3O_5}_{\text{Allophanic Ether.}}.$$

By the action of solutions of caustic, baryta, potash, or soda upon allophanic acid, the allophanates of these bases are produced. Thus, with baryta water, the re-action is

$$\underbrace{C_4H_5O, C_4N_2H_3O_5}_{\text{Allophanic Ether.}} + BaO\,HO = \underbrace{BaO, C_4N_2H_3O_5}_{\text{Allophanate of Baryta.}} + \underbrace{C_4H_6O_2}_{\text{Alcohol.}}.$$

The re-action must be effected without heat, otherwise the allophanate of baryta is decomposed, with the production of carbonate of baryta, carbonic acid, and urea:

$$\underbrace{(BaO, C_4N_2H_3O_5)}_{\text{Allophanate of Baryta.}} + HO = CO_2 + BaO\,CO_2 + \underbrace{C_2N_2H_4O_2}_{\text{Urea.}}.$$

ALLOTROPY. Several elementary substances are known to undergo remarkable changes in their appearance, and in their physical and chemical properties, without entering into combination with any other body, or in any way losing their elementary character. Such elements are said to be *allotropic*, and their different forms are termed *allotropic* modifications. Thus the element sulphur is generally met with as a bright yellow brittle solid, and if it be fused by a heat of about 240°, and then allowed to cool, it assumes again its original appearance, but if whilst fused it be heated more strongly, to 500° for instance, and be then suddenly cooled by pouring it into cold water, it forms a soft amber-brown coloured tenaceous mass, which may be drawn out into threads that are elastic like caoutchouc. At ordinary temperatures this elastic sulphur very slowly returns to its ordinary state, but if it be heated to 212° the transformation is instantaneous, and accompanied with the evolution of heat. There are also other allotropic forms of sulphur all exhibiting marked differences in their properties, but all consisting of the same material—elementary sulphur. Phosphorus and many other elements also exhibit the same phenomenon. The cause of these allotropic modifications is at present enveloped in great obscurity, but it is generally supposed that such modifications are due to a difference in the grouping of the ultimate molecules of the allotropic elements.

ALLOWANCE, in commerce, a deduction from the gross weight of goods, agreed on between merchants, according to the customs of particular countries and ports, the chief of which is known by the name of TARE.

ALLOXAN. [URIC ACID, DERIVATIVES OF.]

ALLOXANIC ACID. [URIC ACID, DERIVATIVES OF.]

ALLOXANTIN. [URIC ACID, DERIVATIVES OF.]

ALLOY. This word is employed to designate either a natural or artificial compound of two or more metals, except when mercury is one of them, and then the mixture is termed an *amalgam*. The natural alloys are far less important substances than those which are artificially procured: thus, arsenic occurs combined with the following metals, namely, antimony, bismuth, cobalt, iron, nickel, and silver; there is also found a native alloy of antimony and nickel, and of antimony, cobalt, and nickel; some others might also be mentioned. But there is no instance of a native alloy, strictly speaking, being applied to any useful purpose, whereas the artificial alloys are of the highest importance both for the uses of common life and for manufacturing purposes; since by uniting different metals, compounds are formed which possess a combination of qualities not occurring in any one metal. Platina is always employed in a pure state, and copper, iron, lead, and zinc, are also very commonly so used; but gold, silver, tin, antimony, and bismuth are generally alloyed; the first three, on account of their softness, and the two latter because they are extremely brittle. Gold and silver are hardened by alloying with copper; copper is hardened by zinc, &c.

The formation of alloys appears to depend upon the chemical affinity of the metals for each other; and in some instances this affinity seems to be wanting, for no combination occurs: thus, according to Gellert, bismuth and zinc do not combine. Various facts may be assigned for supposing the combination to be the result of chemical union. M. Boussingault ('An. de Ch. et de Ph.,' t. 34, p. 408) has described and analysed six different native alloys of gold and silver, and he found in all cases that the metals were combined in definite proportions. The change of properties which metals undergo by combining, furnishes strong evidence of the intervention of chemical affinity and action: thus, with respect to colour, copper, a reddish metal, by union with zinc, a white one, gives the well-known yellow alloy, brass: the fusing point of a mixed metal is never the mean of the temperature at which its constituents melt; and it is generally lower than that of the most fusible metal of the alloy; whilst the power of the latter to conduct heat and electricity, also indicates that chemical combination has occurred.

All alloys formed of brittle metals are brittle; those made with ductile metals are in some cases ductile, in others brittle; when the proportions are nearly equal, there are as many alloys which are brittle as ductile; but when one of the metals is in excess, they are most commonly ductile. In combining ductile and brittle metals, the compounds are brittle, if the brittle metal exceed, or nearly equal the proportion of the ductile one; but when the ductile metal greatly exceeds the brittle one, the alloys are usually ductile. The density of alloys sometimes exceeds, and in other cases is less than, that which would result from calculation; the following alloys afford examples of increased and diminished density.

Increased.		Diminished.	
Gold	and zinc	Gold	and silver
Gold	„ tin	Gold	„ iron
Gold	„ bismuth	Gold	„ lead
Gold	„ antimony	Gold	„ copper
Gold	„ cobalt	Gold	„ iridium
Silver	„ tin	Gold	„ nickel
Silver	„ bismuth	Silver	„ copper
Silver	„ antimony	Iron	„ bismuth
Silver	„ zinc	Iron	„ antimony
Silver	„ lead	Iron	„ lead
Copper	„ zinc	Tin	„ lead
Copper	„ tin	Tin	„ palladium
Copper	„ palladium	Tin	„ antimony
Copper	„ bismuth	Nickel	„ arsenic
Copper	„ antimony	Zinc	„ antimony
Lead	„ bismuth		
Lead	„ antimony		
Platina	„ molybdenum		
Palladium	„ bismuth		

Not only are the properties of metals altered by combination, but different proportions of the same metals produce very different alloys. Thus, by combining ninety parts of copper with ten parts of tin, an alloy is obtained of greater density than the mean of the metals, and it is also harder and more fusible than the copper; it is slightly malleable when slowly cooled, but on the contrary when heated to redness, and plunged into cold water, it is very malleable: this compound is known by the name of *bronze*. If eighty parts of copper be combined with twenty parts of tin, the compound is the extremely sonorous one called *bell-metal;* an alloy consisting of two-thirds copper and one-third tin, is susceptible of a very fine polish, and is used as *speculum metal*.

It is curious to observe in these alloys, that in bronze, the density and hardness of the denser and harder metal are increased by combining with a lighter and softer one; while, as might be expected, the fusibility of the more refractory metal is increased by uniting with a more fusible one. In bell-metal, the copper becomes more sonorous by combination with a metal which is less so: these changes are clear indications of chemical action.

It has been already observed, that the natural alloys, considered as such, are not important bodies; the only one, if indeed that may be so reckoned, is the alloy of iron and nickel, constituting meteoric iron, and of which the knives of the Esquimaux appear to be made. The artificial metallic alloys are of the highest degree of utility: thus, gold is too soft a metal to be used either for the purposes of coin or ornament, it is therefore alloyed with copper; silver, though harder than gold, would also wear too quickly, unless mixed with copper; and copper is improved, both in hardness and colour, by combination with zinc, forming brass.

The following, among other useful alloys, will be treated of under their specific names, viz., BELL-METAL, PEWTER, BRASS, BRONZE, GUN, PRINCE'S, SPECULUM, BRITANNIA, and TYPE METAL, GERMAN SILVER, NICKEL SILVER, TUTENAG, and SOLDERS. Other alloys will be described when the more important metal entering into their composition comes under consideration.

ALMACANTER, an Arabic term now disused, but which, with many others, was formerly employed in astronomy. The name is given to all the small circles parallel to the horizon; so that two stars which have the same almacanter, have the same altitude. Almacanter would now be called a circle of altitude, in the same way as a small circle parallel to the equator, all whose points have therefore the same declination, is called a circle of declination.

ALMAGEST, a name given by the Arabs to the μεγάλη σύνταξις, or *great collection*, the celebrated work of Ptolemy, the astronomer of Alexandria. It was translated into Arabic about the year A.D. 827, under the patronage of the Caliph Al Mamun, by the Jew Alhazen ben Joseph, and the Christian Sergius. The word is the Arabic article *al* prefixed to the Greek word *megistus*, 'greatest,' a name probably derived from the title of the work itself, or, as we may judge from the superlative adjective, partly from the estimation in which it was held.

ALMANAC. The derivation of this word has given some trouble to grammarians. The most rational derivation appears to us to be from the two Arabic words *al*, the article, and *mana* or *manah*, 'to count.'

An almanac, in the modern sense of the word, is an annual publication, giving the civil divisions of the year, the moveable and other feasts, and the times of the various astronomical phenomena, including in the latter term not only those which are remarkable, such as the eclipses of the moon or sun, but also those of a more ordinary and useful character, such as the places of the sun, moon, and planets, the position of the principal fixed stars, the times of high and low water, and such information relative to the weather as observation has hitherto furnished. The agricultural, political, and statistical information which is usually contained in popular almanacs, though as valuable a part of the work as any, is comparatively of modern date.

It is impossible that any country in which astronomy was at all cultivated could be long without an almanac of some species. Accordingly, we find the first astronomers of every age and country employed either in their construction or improvement. The belief in astrology, which has prevailed throughout the East from time immemorial, rendered almanacs absolutely necessary, as the very foundation of the pretended science consisted in an accurate knowledge of the state of the heavens. With the almanacs—if indeed they had them not before—the above-mentioned absurdities were introduced into the west, and strange to say, it is only within the last twenty years that astrological predictions have not been contained in nine almanacs out of ten. It is not known what were the first almanacs published in Europe. That the Alexandrian Greeks constructed them in or after the time of Ptolemæus, appears from an account of Theon, the celebrated commentator upon the Almagest, in a manuscript found by M. Delambre at Paris, in which the method of arranging them is explained, and the proper materials pointed out. It is impossible to suppose that at any period almanacs were uncommon; but in the dearth of books whose names have come down to us, the earliest of which Lalande, an indefatigable bibliographer, could obtain any notice, are those of Solomon Jarchus, published in and about 1150, and of the celebrated Purbach, published 1450–61. The almanacs of Regiomontanus, said by Bailly, in his 'History of Astronomy,' to have been the first ever published, but which it might be more correct to say ever printed, appeared between 1475 and 1506, since which time we can trace a continued chain of such productions, of which our limits will not allow us to give even the names of the authors. They may be found in the 'Bibliographie Astronomique' of Lalande, and in Hutton's 'Mathematical Dictionary,' article 'Ephemeris.' The almanacs of Regiomontanus, which simply contained the eclipses and the places of the planets, were sold, it is said, for ten crowns of gold. An almanac for 1442, in manuscript we presume, is preserved in the 'Bibliothèque du Roi,' at Paris. The almanacs of Engel, of Vienna, were published from 1494 to 1500; and those of Bernard de Granolachs, of Barcelona, from about 1487. There are various manuscript almanacs of the 14th century in the libraries of the British Museum, and of Corpus Christi College, Cambridge.

The first astronomical almanacs published in France were those of Duret de Montbrison, in 1637, which series continued till 1700. But there must have been previous publications of some similar description; for, in 1579, an ordonnance of Henry III. forbade all makers of almanacs to prophesy, directly or indirectly, concerning the affairs either of the state or of individuals. In England the royal authority was less rationally employed. James I. granted a monopoly of the trade in almanacs to the universities and the Stationers' Company. The universities however were only passive, having accepted an annuity from their colleagues, and resigned any active exercise of their privilege.

In 1775 a blow was struck which demolished the legal monopoly. One Thomas Carnan, a bookseller, whose name deserves honourable remembrance, had some years before detected or presumed the illegality of the exclusive right, and invaded it accordingly. The cause came before the Court of Common Pleas in the year above mentioned, and was there decided against the Company. Lord North, in 1779, brought a bill into the House of Commons to renew and legalise the privilege, but, after an able argument by Erskine in favour of the public, the House rejected the ministerial project by a majority of forty-five. The defeated monopolists managed to regain the exclusive market, by purchasing the works of their competitors. The astrological and other predictions still continued; but it is some extenuation that the public, long used to predictions of the deaths of princes and falls of rain, refused to receive any almanacs which did not contain their favourite absurdities. It is said (Baily, 'Further Remarks on the Defective State of the Nautical Almanac,' &c., p. 9) that the Stationers' Company once tried the experiment of partially reconciling Francis Moore and common sense, by no greater step than omitting the column of the moon's influence on the parts of the human body, and that most of the copies were returned upon their hands.

The 'British Almanac' was published by the Society for the Diffusion of Useful Knowledge in 1828. Its success induced the Stationers' Company to believe that the public would no longer refuse a good almanac because it only predicted purely astronomical phenomena, and they accordingly published the 'Englishman's Almanac.' We may also add that other almanacs have diminished the quantity and tone of their objectionable parts. But astrology still puts forth a timid voice in the name of Francis Moore; and there are professedly astrological almanacs, which have their purchasers, and probably their believers.

Of the professedly astronomical almanacs, the most important in England is the 'Nautical Almanac,' published by the Admiralty, for the use both of astronomers and seamen. This work was projected by Dr. Maskelyne, then Astronomer Royal, and first appeared in 1767. The employment of lunar distances in finding the longitude, of the efficacy of which method Maskelyne had satisfied himself in a voyage to St. Helena, required new tables, which should give the distances of the moon from the sun and principal fixed stars, for intervals of a few hours at most. By the zeal of Dr. Maskelyne, aided by the government, the project was carried into effect, and it continued under his superintendence for forty-eight years. During this time it received the highest encomiums from all foreign authorities, for which see the French 'Encyclopédie,' art. 'Almanach,' and the Histories of Montucla and Delambre. From 1774 to 1789 the French 'Connaissance des Tems' borrowed its lunar distances from the English almanac. On the death of Maskelyne it did not continue to improve, and, without absolutely falling off, was inadequate to the wants either of seamen or astronomers. In consequence of complaints of this work, which were almost universally allowed by astronomers to contain a great deal of truth, the government, in 1830, requested the opinion of the Astronomical Society upon the subject, and the Report of the Committee appointed by that body, which may be found in the fourth volume of their 'Transactions,' is a sufficient proof of the opinion of practical astronomers on the previous state of the work. The alterations proposed by the Society were entirely adopted by the government, and the first almanac containing them was that for 1834. It is now conducted under the superintendence of J. R. Hind, F.R.A.S.

The 'Supplements' which it had been customary to publish have been discontinued. The 'Nautical Almanac' is brought out two or three years in advance.

This country was forestalled in most of the important changes just mentioned by the Berlin 'Ephemeris,' published under the superintendence of Professor Encke. Its predecessor, the 'Astronomisches Jahrbuch,' was conducted for fifty years by the celebrated Bode; and was entirely remodelled by Encke in 1830. Of other works of the same kind, published on the Continent, those of Coimbra and Milan are among the most valuable; the latter was commenced in 1755, by M. de Cæsaris.

The oldest national astronomical almanac is the French 'Connasisance des Tems,' published under the superintendence of the Bureau des Longitudes at Paris. It was commenced in 1679 by Picard, and continued by him till 1684. It then passed through the hands of various astronomers till 1760, when the conduct of it was given to Lalande, who, besides other alterations, first introduced the lunar distances, which have been already alluded to. At present the plan is very similar to that of the new 'Nautical Almanac,' with the addition of very valuable original memoirs which appear yearly. In fact, we may say generally, that the original contributions to the various Continental almanacs are among their most valuable parts; and, as Professor Airy remarks ('Reports of the British Association,' &c., p. 128), "In fact nearly all the astronomy of the present century is to be found in these works," that is, in certain periodicals which are mentioned, "or in the 'Ephemerides' of Berlin, Paris, or Milan." The 'British Almanac,' from its commencement, endeavoured to attain somewhat of a similar character, by the issue of a 'Companion to the Almanac,' not confining the subjects to astronomy only, but embracing a variety of scientific and statistical information. 'The Book of Almanacs,' by A. de Morgan, published in 1851, is furnished "with an Index of Reference by which the almanac may be found for every year up to A.D. 2000, with the means of finding the day of any new or full moon from B.C. 2000 to A.D. 2000;" a useful and valuable work for reference.

Next to the 'Nautical Almanac,' ranks, as an astronomical almanac, White's 'Ephemeris,' a work nearly as old as the monopoly previously described. For many years past this publication has given astronomical data sufficient to enable the seaman to find his latitude and time. The 'Gentleman's Diary,' commenced in 1741, and the 'Ladies' Diary,' in 1705, powerfully aided in keeping up a mathematical taste, to a certain extent, throughout the country, by annually proposing problems for competition. Several persons who afterwards became celebrated in mathematics, have commenced their career by the solution of these problems.

The stamp duty on Almanacs, which, at fifteen-pence per copy, produced on an average about 31,000*l*. a-year, was repealed by the 3 & 4 Will. IV. c. 57, August 13th, 1834. Since that period many important improvements have been effected in almanacs of older standing, and numerous excellent new publications of this class have appeared, many of them at a very low price, which have commanded an extensive sale; but many others of a low and worthless character are also continually springing into existence. A great number of local almanacs, were also called into existence, which in many cases are excellent supplements to the general almanacs of London.

ALME, or **AL-MAI**, that is, 'the learned,' the name given by the modern Egyptians and Arabs to the singing girls of Egypt. The word *alma* seems to be corrupted from the Arabic *âlimeth*, the feminine form of the active participle *âlim, sciens, sapiens.* The professional male singers, who are also frequently dancers, are called Alewayeeh. These Almai live together in bands, which are distributed in the various towns, or travel about the country in quest of employment. They are present at festivals and marriages, and other ceremonies. Those who are admitted into the society have generally a fine voice; they learn by heart the best songs on romance and love; and some are able to sing extempore verses, after the manner of the Italian improvisatori. They are admitted into the harems of the great, where they instruct the women in dancing and singing, or amuse them by reciting poems. They excel in singing pathetic ballads: dwelling upon plaintive tones, they inspire a feeling of melancholy, which, insensibly increasing, draws tears from the eyes. The Turks, enemies as they are to the arts, pass whole nights in listening to them.

The Almai also accompany funerals, at which they sing dirges, and utter groans and lamentations, like the Præficæ of Sardinia, Corsica, and other European countries. The higher and more accomplished class of the Almai attend none but wealthy people, and their price is high. The common people however have also their Almai, who try to imitate the superior class, but have neither their elegance, grace, nor knowledge. They are seen everywhere; the public squares and the walks round Cairo abound with them. Their morals are as licentious as their songs. Although there are Almai in Syria and other parts of the Ottoman empire, yet Egypt seems to have been at all times their favourite and, as it were, their native country.

The Almai have been not unfrequently confounded with the Ghawazee, or dancing girls of Egypt; but though some of the lower class of Almai may sometimes dance, the professions are distinct. The Ghawazee are accustomed to perform in the public streets; they are never admitted into a respectable harem, but are not unfrequently hired to entertain parties of dissolute men. They dance unveiled, with little grace; but the suppleness of their bodies is very great, as well as the flexibility and expression of their features, and the indecency of their attitudes is excessive. They, as a class, are among the most abandoned of the courtesans of Egypt; but in 1834 the government interfered, and public female dancing was prohibited; the punishment for infringing the regulation was, for the first offence, fifty stripes, and for subsequent offences, imprisonment with hard labour. Men committing a similar offence were to be punished by the bastinado. It is feared however, that this law, though well intended, may be, and is, too frequently and too easily evaded. The Bayaderes of India combine, to some extent, the characteristics of the Almai and Ghawazee.

(Savary, *Letters on Egypt*; Lane's *Modern Egyptians*; Mrs. Poole's *Englishwoman in Egypt.*)

ALMONER, anciently written Amner, was an officer in a king's, prince's, prelate's, or other great man's household, whose business it was to distribute alms to the poor. Previous to the Dissolution, every great monastery in England had its almoner. The almoner of the king of France was styled his Grand Aumonier, and there was a similar office at a very early period attached to the household of the popes.

'Fleta,' a juridical treatise of the time of Edward I., describes the duties of the high almoner as they then stood in England. He was to collect the fragments of the royal table, and distribute them daily to the poor; to visit the sick, poor widows, prisoners, and other persons in distress; he reminded the king about the bestowal of his alms, especially on saints'-days; and was careful that the cast-off robes, which were often of high price, should not be bestowed on players, minstrels, or flatterers, but their value given to increase the king's charity.

In modern times, the office of lord high almoner has been long held by the archbishops of York. There is also a sub-almoner. The hereditary grand-almoner is the Marquis of Exeter. An account of the lord almoner's annual distribution in the sovereign's name, on the Thursday before Easter, will be found under MAUNDY THURSDAY. There is an office at Westminster appropriated to the business of the almonry.

Ducange in his 'Glossary,' gives other meanings of the word almoner. It was sometimes used for those who distributed the legacies of others, and who have been since called executors; sometimes for a person who had left alms to the poor; and sometimes for the poor upon whom the alms were bestowed. The 'eleemosynarii regis,' or persons who were supported by the king's bounty, occasionally noticed in the Domesday Survey, were of this last description. Almoner is a name also given in ecclesiastical writers to the deacons of churches.

ALMS-HOUSE, an edifice, or collection of tenements, endowed, generally, by private benevolence, with a revenue for the maintenance of a certain number of poor, aged, or disabled people. England is the only country which possesses alms-houses in abundance, though many such exist in Italy. In England they appear to have succeeded the incorporated hospitals for the relief of poor and impotent people, which were dissolved by King Henry VIII.

ALOES.—*Medical Properties of.*—Though known to the ancients and largely used in modern times, the sources of this drug are not accurately determined. It seems better to follow the plan of the 'Edinburgh Pharmacopœia,' and assign it to an undetermined species of the genus Aloe. Barbadoes aloes would appear to be procured from the *A. vulgaris*, a plant native of Greece, and which furnished the aloes of the ancients, and which is now cultivated in the West Indies, as well as Spain, Italy, and Sicily, from which latter countries France and other Continental nations, but not Britain, are often supplied. This plan seems the more judicious, as the commercial varieties, however designated, or whencesoever derived, are to be found of nearly every degree of excellence or worthlessness, if care be not taken in the mode of obtaining the article. Sir W. O'Shaughnessy, whose position in the East gives him good opportunities of observing, states, in his 'Bengal Dispensatory,' that "the quality of the product is apparently more dependent on soil, climate, and preparation, than on specific differences in the plant." Not only has Barbadoes aloes become less valuable from changes in the mode of collection, but even the real Socotorine aloes has become deteriorated, from any person in the island of Socotra being at liberty to cut as many leaves of the now neglected plant as he pleases, and prepare it in any way he likes, instead of the care formerly bestowed on it. "Formerly every part of the island produced the aloe; and the whole was farmed out to different individuals, the produce being monopolised at a fixed price by the Sultan. The boundaries, however, thus set up, which consisted of loose stone walls, and were carried with immense labour over hill and dale, though they still remain, under the present unsettled government no longer distinguish property. The descendants of the owners to whom the several fields were formerly allotted, have either withdrawn their claims, or these are forgotten. At present, any one who chooses to take the trouble, collects the aloe-leaves, and nothing is levied on account of the Sultan." (Lieut. Wellsted, 'Memoir on the Island of Socotra,' in 'Journal of Royal Geogr. Society,' vol. v. p. 197.) In the language of the island the aloe is called Tayef; by the Arabs, Soobah. Though this island possesses plants sufficient to yield nearly all the aloes required in commerce, very little is now obtained from it; and what passes under the name of Socotorine aloes is almost entirely the best East Indian sort, as is rendered further evident by its being exported from Bombay. When one source of any article of commerce is dried up, it is the custom of the dealers to bestow the name of the sort in greatest repute on the best they possess; meaning, not that it is the produce of the place the name of which it bears, but that it possesses the qualities of the kind originally obtained from that part. Alterations in commerce, dependent on a variety of causes, are constantly rendering implicit reliance on names a very unsafe guide.

Attention to the mode of extracting the juice might render aloes, whencesoever procured, of excellent quality; but it will be seen presently how little the ordinary methods are calculated to ensure this end, quantity rather than quality being aimed at by the preparers. The aloe, like the hyacinth and many other liliaceous plants, contains a vast quantity of a mucilaginous matter (vegetable albumen?), more abundant towards the centre of the thick fleshy leaves than near the surface. The medicinal juice is altogether different from this, and is contained in a distinct set of vessels (Opangia, Link; Opophora, vasa lactifera), which are distributed chiefly under the thick cuticle of the leaves. Out of these vessels the juice sometimes exudes, either from turgescence or from the punctures of insects, and concretes into tears, forming that variety of aloes called *Aloe lucida*, seen occasionally as a curiosity, but not met with as a commercial article. (The term *A. lucida* is applied by Geiger and Theod. Martius to fine Cape aloes, but it is quite distinct from that now spoken of.) If transverse but not deep incisions were made at various points and at proper distances in the course of the leaves while yet attached to the stem, much fine aloes could be procured by scraping off the juice from time to time as it flows, or allowing it to become concrete and then picking it off. The general practice, however, is to cut off the leaves near the base, and put their open ends into a skin, into which the juice flows. This is afterwards inspissated, either by spontaneous evaporation in the sun, or promoted by a gentle heat. Pressure of the leaves is sometimes made to assist the flow, but by this means "large quantities of viscid mucilage are forced out, and mix with the proper bitter juice, which is proportionately deteriorated." (O'Shaughnessy.) Dipping the leaves into hot water, by which their vitality is lessened or destroyed, and their hygroscopicity diminished, is equally objectionable, as the viscid mucilage then flows out more freely. Worst of all is the plan now, but not formerly, pursued in Barbadoes. Barbadoes aloes of the present day is the extract of a decoction. "It is made by immersing for ten minutes in boiling water the chopped leaves previously enclosed in cloths or wicker baskets, increasing the strength of the decoction with repeated supplies of chopped leaves till the water is fully charged; then allowing the liquor to cool and the sediment to settle; and finally evaporating the clear liquor with caution till it is concentrated sufficiently to become solid on cooling. The hot liquor is allowed to concrete in large gourd-shells, in which it is always transported to Europe." (Christison.) From these different plans of collecting and inspissating the juice, results an article which differs considerably in appearance and greatly in value. Aloes is one of the few drugs in which adulteration is not extensively practised, further than by substituting the inferior and low-priced kinds for the superior. When carelessly prepared, sand and fragments of leaves and skins are frequently found in the samples.

A few of the most important sorts found in commerce may be noticed. The finest sort, to which the term Socotorine aloes is given, can scarcely be regarded as one of daily occurrence, and is noticed merely as a standard of excellence by which to judge of others according to the degrees in which they approximate it. "It consists of small angular fragments, possessing a deep garnet-red colour, altered somewhat by exposure to the air; a conchoidal fracture, a resinous lustre, much translucency in thin layers, a beautiful garnet-red hue by transmitted light, and a peculiarly fragrant odour. It is brittle, easily pulverisable, and of a fine golden-yellow tint when in powder. It is almost entirely soluble in spirit of the density of 950°, a very scanty light flocculent matter being left." (Christison.) As specimens decline from this unusually high standard, the lustre diminishes, the fracture is rougher, the odour less pleasant, the solubility less, they are not so readily pulverisable, the powder is of a deeper colour, inclining to brown, the residuum greater, and consisting of more of the flocculent matter, as well as incidental impurities. In regard to the amount of insoluble matter, Barbadoes aloes contains the most, varying from 5 to 12 per cent.; and it is much more difficult to reduce to powder, as the mode of obtaining it explains.

The chief varieties go by the name of—Socotorine; East Indian, called also frequently *hepatic;* and Cape aloes (*Aloe lucida* of Geiger and Theod. Martius), also called *A. Cabo.* Innumerable subvarieties of these are found. Caballine, or *horse* aloes, has nearly disappeared from commerce, refinement or fashion in veterinary medicine deeming it not fit for horses.

Barbadoes aloes comes to this country in the gourds and calabashes into which it is poured when prepared. Each of these weighs from sixty to even eighty pounds. When broken, the fracture is sometimes conchoidal, seldom lustrous, and having a more liver-like aspect, better entitling it to the designation of *hepatic*, by which it is frequently called, than any of the others.

The chief chemical constituents of aloes are *aloesin* (or the saponaceous principle); *resin*; *vegetable albumen*, absent from the best kinds; *gallic acid*, a trace according to Trommsdorff; *aloetic acid*, according to Pereira. Aloes is however of rather a more complex nature than appears from this view. Aloesin, or aloe-bitter, is entirely soluble in cold water, but not in absolute alcohol. When hot water is used, something is taken up, which is deposited as the water cools: to this the name of resin has been given, perhaps not with perfect propriety. The aloesin is looked upon as the cathartic principle of aloes, the resin rather as an irritant and objectionable ingredient. Hence in some of the 'Pharmacopœias' an extract is ordered to accomplish their separation; a proceeding altogether unnecessary, when aloes of the best quality can be obtained by giving a proper price for it. The formation of a decoction by heat is still more objectionable, as a much superior preparation is made by cold water alone, more grateful to the stomach and not less effective if given in rather larger dose.

Few more valuable drugs exist, as is proved by the numerous preparations made either of aloes alone, or with some other articles combined with it. These combinations have various objects in view, some to heighten its powers, others to modify, and some to get rid of certain well-founded objections to its effects. The chief of these are noticed here.

In large doses it is decidedly aperient, but is unlike many other cathartics in so far that increasing the dose beyond a certain point by no means increases the effect. This can be accomplished however by associating it with other cathartics, and still more decidedly by uniting it with tonics, such as iron or quinia. Aloes and quinia with antimonial powder, and aromatic powder to cover the unpleasant taste, form a combination of great utility in many gastric derangements, especially where the head is implicated. Thus, when persons are so fortunate as to be rallying from the stage of collapse in Asiatic cholera, this combination given frequently improves the secretions and abates the fever. In some fevers with numerous liquid motions it may also be given with striking benefit, the motions diminishing in frequency and increasing in solidity, as well as becoming of a more healthy appearance. In the congested state of the bowels and brain which precedes water in the brain, aloes, either in this combination or in some other form, is of great utility. (Yeats 'On Water on the Brain.') Persons predisposed to apoplexy are more benefited by aloes than by most other purgatives, especially if they have been previously subject to a hæmorrhoidal flux which has been suppressed.

The combination which increases the purgative power of aloes in the most remarkable degree is formed by adding one drop of strong (undiluted) sulphuric acid to four grains of the best aloes, and forming a pill, two of which, given every two, four, or six hours, will almost invariably relieve the most obstinate cases of constipation, such as occur in painters' cholic, ileus, and other diseases. It is even more efficacious than croton-oil, and not so apt to excite inflammation of the intestines. This augmentation of power seems to be in conformity with a general law, by which many vegetable principles have their properties heightened by adding an acid, either mineral or vegetable. Thus ammoniacum becomes a more powerful expectorant by adding dilute nitric acid to the mistura ammoniaci; and the fœtid gums, such as assafœtida, are rendered more potent by solution in vinegar. ('Acetum Antihystericum,' formula No. 1, in Copland's 'Dictionary of Medicine.')

Aloes, especially the compound decoction, is a most valuable emmenagogue, particularly when combined with tincture of ergot or preparations of iron. From its action on the lower part of the bowels it is deemed an improper purgative in pregnancy or during the menstrual flux. It is also considered improper for persons subject to piles. This objection has been attempted to be obviated by various means; but the best way is to combine it with other agents, as stated by Dr. Christison, as many persons can take the compound gamboge-pill, or compound extract of colocynth, who cannot take aloes alone. The best means of covering the unpleasant taste of aloes, when given in the liquid form, is the compound tincture of lavender.

ALOETIC ACID (HO, $C_{14}H_{2}(NO_{4})_{2}O$, Aq. ?), a resinoid acid, found by Schunck in the products of the action of nitric acid upon extract of aloes. It forms red salts.

ALÖIN. ($C_{34}H_{18}O_{14}$?) Stenhouse obtained this substance from the cold aqueous extract of Barbadoes aloes by evaporation in vacuo. It is deposited in coloured granular crystals, which after pressure between folds of bibulous paper, recrystallisation from water, drying at a temperature not exceeding 150°, and final recrystallisation from alcohol, present the appearance of groups of pale yellow needles. Aloïn is the active purgative principle of aloes. It is neutral to test papers, possesses an intensely bitter taste, and is rapidly changed at 212°. Caustic and carbonated alkalies dissolve it, forming orange-coloured solutions. Cape and Socotrine aloes also yield aloïn, but it is more difficult to purify when prepared from these varieties.

ALONSINE, or ALPHONSINE, TABLES, an astronomical work, which appeared in the year 1252, under the patronage of Alonzo X., in the first year of his reign. They contain the places of the fixed stars, and all the methods and tables then in use for the computation of the places of the planets; but they are not made from original observations, nor is there any material difference between the astronomy contained in them and that of Ptolemy, except in two points. The length of the year is supposed to be 365 days, 5 hours, 49 minutes, and 16 seconds; which is a more correct value than had been given before, being only 26 seconds over the best modern determinations. The mean precession of the equinoxes is stated at half its real amount; being such as would carry the equinoctial points round the circumference of the globe in 49,000 years. An inequality, however, is supposed, having a period of 7000 years, by which the mean precession is alternately augmented and retarded 18 degrees. It is difficult to say whence a theory so utterly at variance with the phenomena could be derived. The general opinion is, that these tables were constructed by Isaac Ben Said, a Jew, but others suppose that Al Cabit and Aben Ragel, the preceptors of Alonzo, were the real superintendents. The numbers above cited, in speaking of the precession, have been supposed from their connection with the number 7, and the difficulty of accounting for them otherwise, to have been the ideas of a Jew. These tables are constructed for the meridian of Toledo, and the epoch 1256. They were not held in much esteem by succeeding astronomers. Regiomontanus says, "beware lest you trust too much to blind calculation and Alphonsine dreams." And Tycho Brahé, who reports that 400,000 ducats had been spent upon them, laments that this sum had not been employed in actual observation of the heavens. A full account of their contents may be seen in Delambre, 'Hist. de l'Ast. du Moyen Age,' p. 248. Till the time of Copernicus and Tycho Brahé they continued in general use, being in truth, with some modifications, a body of Ptolemaean astronomy. They were first printed in 1483 by the celebrated Ratdolt of Venice. A copy of this *editio princeps* is in the Royal Library at Paris. There have been several subsequent editions.

ALPACA-WOOL. The natural history of the Alpaca, or Paco, has been treated under LLAMA, in the DIVISION OF NATURAL HISTORY; we here notice only the application of the wool to manufactures.

The introduction of this wool has attracted considerable attention; and the question of naturalising the alpaca in this country, in Germany, and in Australia, is also an object of much interest. The wool of the alpaca is superior to English wool in length, softness and pliability. The fleece averages from 10 to 12 lbs., while that of our sheep is seldom more than 8 lbs.; and while the staple of English wool does not often exceed six inches in length, that of the alpaca varies from eight to twelve inches. The lustrous appearance of the alpaca wool renders it applicable to many of the purposes for which silk is usually employed in textile fabrics; and it is found a useful substitute for Angora wool. The manufacture of plain and figured stuffs from the fleece of the alpaca was commenced at Bradford in Yorkshire, a number of years ago, and these fabrics have been much admired. The consumption of alpaca wool in this country in the seven years ending December, 1843, is estimated by Mr. Walton at 12,000,000 lbs.; it has since largely increased. Towards the close of 1844 five different articles were manufactured at Bradford for her Majesty, from the wool of an alpaca which had been kept at Windsor. The fleece weighed 16½ lbs., and when sorted and combed 10 lbs., including 1 lb. of white wool, the remainder being almost entirely jet black. One of the articles manufactured was an apron, in which the wool of the alpaca, without the admixture of any other wool, was used for the first time in this country; for though very large quantities have been woven at Bradford, it has usually been in fabrics where the warp was of cotton or some other material, and the weft only of alpaca. Three of the other articles manufactured for her Majesty were a striped and figured dress; the warp consisting of rose-coloured silk, and the weft of black alpaca with figures on alternate grounds of alpaca and silk. This dress, which measured 12 yards, required 2½ lbs. of alpaca. A plaid dress, measuring 15 yards, and containing 2¼ lbs. of alpaca, was woven with an intermixture of silk and worsted. Another article was a plain black alpaca lustre dress, the warp of fine cotton twist, and the weft of alpaca. This required 3½ lbs. of alpaca, and when taken from the loom it resembled silk from its lustrous quality, and was of course much softer.

The question of naturalising the alpaca has been taken up with great enthusiasm by a few persons; but very little progress has yet been made in convincing the country of its practicability. The alpaca inhabits the mountainous and inhospitable regions of Peru, and is remarkable for its abstemiousness. It thrives on coarse food. Those which have been brought to this country have been confined in parks and richly cultivated lands, and have been treated with too much care and tenderness. Mr. Walton asserts that they will live where our hardiest sheep would starve, and that the wildest parts of Great Britain are best suited to their habits. In the 'Transactions of the Highland and Agricultural Society,' 1844, there is an account, by Mr. Stirling, of the attempt at that time being made to introduce the alpaca into Scotland. During the severe winter of 1843-4, when sheep required to be regularly fed with turnips and hay, the alpacas perseveringly sought their own food, and did not experience a single day's illness. Mr. Stirling says that they were kept within enclosures better than sheep, and never attempted to leap a fence. In 1841 the Highland and Agricultural Society offered their gold medal for 'a satisfactory account, founded on actual observation and experiment, of the attempt to naturalise the alpaca in Scotland;' and in 1844 a prize was offered by the Society for the best pair of alpacas born and bred in Scotland, and the best two, male and female, imported. If, as Mr. Walton states, the alpaca may be pastured on lands which are now waste and unprofitable, and where the hardiest sheep would starve, the naturalisation of the animal would undoubtedly prove a great 'national benefit;' but if this is not the case, it is a question whether a constant demand for the wool as an article of import would not be quite as beneficial. The Peruvians would be induced to bestow greater care on the management of their flocks, and the possession of so valuable an export would bring them under influences of a civilising nature, which would render them better customers for our commodities. The expense of importing the alpaca is very great, and the long voyage kills more than two-thirds of the number shipped. Some of the Australian sheep-farmers are now (1859) making renewed attempts to naturalise the alpaca in that country.

Alpaca is now used to a remarkable extent in manufactures. Umbrellas, paletôts, and various articles and garments are made of it: as it presents a sort of compound of the qualities of silks and woollens. Mr. Titus Salt, of Bradford, has built one of the largest and most magnificent factories in the world, chiefly for the production of textile goods made wholly or partially of alpaca; nearly half a million sterling has been spent in the various buildings, dwellings, and machinery. The establishment almost constitutes a town in itself, and has been fancifully named *Saltaire*, by a combination of the name of the owner with that of the river, on the banks of which the factory stands.

The late Earl of Derby's ménagerie at Knowsley, sold by auction in October, 1851, contained eleven alpacas, which were born and bred on the estate.

ALPHABET is the name given to the series of letters used in different countries at different times. The term is borrowed from the Greek language, in which *alpha, beta*, are the first two letters; or if we go a step further back, we should derive the word from the Hebrew, which gives to the corresponding letters the names *aleph, beth.* Thus the formation of the word is precisely analogous to that of our familiar expression, the *A, B, C;* and some writers have found a similar origin for the Latin name given to the letters, namely, *elementa*, which it must be allowed, bears an extraordinary similarity in sound to the three liquids, *l, m, n;* but to make this derivation satisfactory, it should be proved that these letters were at one time the leaders of the alphabet, for otherwise it would be difficult to account for the selection of a name from them in preference to the rest.

Among the different causes which have promoted the civilisation of man, there is none, we might almost say, which has been so fruitful as the invention of the alphabet; and the very circumstance of the invention being essential to this effect, and therefore preceding it, has made it a task of some difficulty to point out the mode in which the discovery was made, for historical evidence upon such a point must be very imperfect. The present age however has nearly surmounted this difficulty, and we begin to see pretty clearly at least how the discovery *might* have been made, perhaps how it actually was made. Oral language itself, we might almost infer *a priori*, originated in an attempt to imitate, by the organs of the human voice, those different sounds which nature, in her animate and inanimate forms, is constantly presenting to our ears. By his powers of articulation man could imitate those sounds at pleasure, and thus recall to the minds of those around him the notion of absent objects and past actions with which the sounds were connected. Thus, in its various forms and combination the single principle of *sound* would afford a vast number of symbols which might be made to represent, at first, the material objects of nature, or the action of those objects upon one another. The transference of these signs from particular objects, that make an impression on the *ear*, to the expression of abstract qualities, would be governed by the same principles of association. That such must have been the origin of spoken language, reason would seem to point out, and the historical investigation of the subject strongly confirms the theory. On the other hand, the language which takes the *eye* for its channel of communication with the mind, would in its first steps be more direct and more simple. The objects of nature and many of the external relations between them were easily represented to the eye with more or less rudeness, by a stick upon sand, and by many other means of graphic imitation which even the savage may command. Yet when we compare these two modes of language with one another, we shall soon perceive that *sound* is a more convenient medium of ordinary communication, if it be only for the reason that the voice is ever with us, and that the ear is ready to receive impressions from every direction, above, below, and around us. A deaf and dumb savage who should wish to depict to a friend an object upon the sand must first catch the attention of his companion by the sense of touch, just as in modern manufactories where the speaking-pipe is used, a bell is attached to it, the ringing of which first directs the party who is to be addressed to apply his ear to the other extremity of the pipe. The result of a comparison then between these two forms of language may, perhaps, be fairly stated thus. The language of pictorial symbols is more easily invented and understood at first. The other, when once invented and understood, is better adapted for the ordinary uses of life. The difficulty of invention, however, is a difficulty that occurs but once; the difficulties in the after use of the language, such as they are, never cease. In the last place, sound travels without the aid of light. It is therefore natural to conceive that oral language would approach a comparatively perfect form with much greater rapidity than that which addresses itself to the eye. At the same time the two forms of language might well be used to some extent simultaneously, as indeed is even now not unfrequently the case—gesture being called in aid.

But the time would soon come when it would be desirable to record for a shorter or longer time the acts and thoughts and commands and duties of man; and here the language of the voice would utterly fail, while the other might ensure a continuance of existence, depending upon the nature of the material on which the representation might be made. In less than a second the sound of the human voice dies away, but the picture even on the sea-sand lasts until the next tide washes it away; the waxen tablet would preserve its characters long enough for the purposes of epistolary communication; the papyrus, the cloth of linen and cotton, the bark of trees, the harder woods, the skins of animals, would retain the impressions upon them for centuries; and lastly, bricks, and stone, and metal, under favourable circumstances, might convey their records to a posterity of many thousand years. Now, to represent visible actions and visible objects would, as we have already stated, be an easy affair, and the signs for abstract qualities might be obtained, as in sounds, upon the principle of association. But instead of forming a new series of associations, which would not easily become generally intelligible, it would no doubt be found more convenient occasionally to turn to account the already existing language of sound. A few examples may perhaps explain our meaning. Visible objects, in the first place, may be directly represented. No pictorial symbol of an *ox* can so readily convey that notion to the mind as the representation of the animal itself, or, in order to save time, that part of the animal which is most characteristic of it might, and would, be selected; in the present case we should propose the head of the animal with its horns. To signify a visible action, such as *fighting*, we should, perhaps, avail ourselves of the *fist*, as the natural organ for that purpose belonging to man, following therein the same direct principle of association which has formed the Latin word *pugnare*, to fight, from the element *pugnus*, or rather *pug*, a fist. In this way we should form a series of symbols altogether independent of the language of sound; but we repeat, it would often be more convenient to make the language of visible signs in part dependent upon the oral symbols. This may be most simply effected by what is in fact a species of punning: If, for instance, a symbol were required of an Englishman for the abstract notion of *friendship*, he might employ the two separate signs for a *friend* and a *ship*; the first of which we will suppose to be *two hands clasped*, the other, of course, *a hull with a mast* and enough *rigging* to distinguish it from other objects. We should thus have two pictorial symbols, which would separately excite in the mind first the *notions*, and then the oral names of *friend* and *ship*, and the combinations of these sounds would recall that new notion, for which the articulate sounds of the word *friendship* are already the conventional symbol. Books of amusement for children, as is well known, have been formed upon this principle; for example, such a sentence as—*I saw a boy swallow a gooseberry*, might be representented by uniting the pictures of an *eye*, a *saw*, a *boy*, a *swallow*, a *goose*, and a *berry*.

So far we have only considered what the origin of written language might have been. The records still existing of the Egyptians have enabled modern discoverers to deduce with an evidence closely approaching to certainty what it actually was. The hieroglyphic characters of Egypt bear upon the very face of them decided proof that they are in their origin pictorial emblems; and that they constitute a language, appears incontrovertibly from the triple Rosetta inscription, the Greek version of which expressly affirms, that the decree contained in the inscription was ordered to be written in three different characters; the sacred letters, the letters of the country, and the Greek. The second of these classes has been called the *enchorial*, from the Greek term (εγχωριος) signifying *of the country*, or else *demotic* (δημοτικος) that is, *of the people.* But although the hieroglyphic characters may be for the most part pictorial emblems used directly for the objects which they represent, or metaphorically for other associated ideas, it has been established by most satisfactory evidence, that they were also in some cases representatives of articulate sound, not, however, of the whole oral name belonging to their original object, but solely of the initial letter, or perhaps syllable. This use of the sacred pictorial characters as symbols of sound was perhaps originally confined to the expression of proper names. Such, for instance, is their use in the hieroglyphic division of the Rosetta inscription for the name of Ptolemy and in another inscription for that of Cleopatra. Thus the former name might be expressed hieroglyphically in our own language by the pictures of *a pig, a top, an owl, a lion*, and *a mouse*. It should be added, however, that when the sacred symbols are used with this phonetic or vocal power for royal names, they are included in an oval ring or cartouche. The enchorial character seems at first to bear little or no resemblance to the hieroglyphic; but a comparison of various manuscripts that have been found in mummies, containing parallel passages in the two characters, has led to the certain conclusion that the enchorial themselves have arisen from the degradation or corruption of the sacred pictorial characters. Dr. Young, in his excellent article on Egypt, in the Supplement to the 'Encyclopædia Britannica,' has given specimens which are perfectly sufficient to establish the connection. The subject, however, of Egyptian writing in its different forms requires an investigation of so many details, that we must refer our readers to HIEROGLYPHICS. We must here be satisfied with stating what appears to us to be a safe conclusion, that a language originally hieroglyphic, would naturally wear away until the characters lost nearly all trace of their original formation on the one hand, and became eventually the mere representatives of phonetic powers, first perhaps as syllables, afterwards as mere letters.

The Hebrew alphabet again affords double evidence of the same nature. The names of the letters, it is well known, are also the names of material objects, some of the very objects in fact, which would be well adapted to pictorial representation. A part of these names, it is true, are obsolete in the Hebrew language as at present known, that is, the authority for their meaning is solely traditional, as they are not found in the existing writings of the language; but this fact, while it affords evidence that the names are not the result of forgery, is precisely what must necessarily have occurred in those changes to which all language is exposed in the long course of ages. We have given a table with the Hebrew names of the letters, which it will be seen have been borrowed, with slight changes, for many other alphabets. But it will be objected that in fact the letters, whatever they may be called, bear no pictorial resemblance to the objects which it is pretended they represent. If the Hebrew characters alone be considered, this objection will not be unreasonable. But there is strong reason for believing that the present Hebrew characters are of comparatively modern date, and if so, there is nothing very violent in the supposition that they may have been derived by degradation from an earlier pictorial form, as the enchorial of the Egyptians, it is now established, arose from the corruption of their hieroglyphics. But not to rely too strongly upon theory, we may appeal to what are virtually *Hebrew* alphabets, though called Phenician and Samaritan. In Plate I. (col. 240) Nos. 2, 3, 4, 5, the reader will see specimens of these alphabets. The first two are taken from Boeckh's 'Inscriptions,' pp. 523, 527, and from the coins given by Mionnet. The Samaritan characters are taken solely from Mionnet. Now among these, we find a few at least, which, even to the sober minded, bear considerable resemblance to the natural objects. The first letter in these alphabets, *aleph*, it is well known means *an ox*; indeed, the terms ελεφας, *elephas, elephant*, of the Greek, Latin, and English languages, seem to be derived from this Hebrew name. If in Syria the name *aleph* was extended to the *elephant*, just as the Greeks applied their term *crocodile*, properly a *lizard*, to the monster of the Nile—when the word came to the Western nations in connection with the *elephant*, the original sense would be readily lost in the secondary. The Romans too called the same animal *Bos Lucas*, the *Lucanian Ox*. We have already stated that the most simple mode of representing an ox would be by a picture of its head and horns, and if any one will turn the engraving of our second Phenician character, so as to have the angular point downwards, he will see a very fair picture of an ox's head, with its two horns and ears into the bargain. Those who are determined to take nothing for a representative of an ox that has not a body, four legs and a tail, may be asked to account for the astronomical figure of *Taurus* in the zodiac.

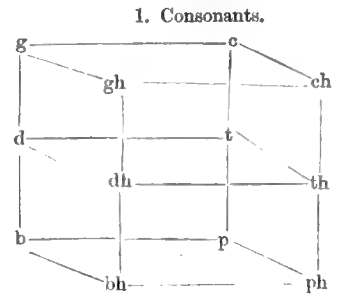
Again, the Hebrew name for the letter *m* was *mem*, and this also was the name for water. Now a very ordinary symbol for water is a zigzag line, which is no doubt intended to imitate undulation or rippling. We find this symbol for *Aquarius* in the zodiac, and we find it also in Greek manuscripts, both for θαλασσα the sea, and ὑδωρ water, the former word having the symbol inclosed in a large circle or *theta*, the latter having its aspirate duly placed above the waving line. Indeed every boy in his first attempt to draw water, represents it by a zigzag line. But before we point out in the written characters what we look upon as representing the wave, or (to be candid) as being the corrupted remains of what once was a wave, we must premise a few words on the characters of the older Western languages. We have already asserted our belief, that the Hebrew characters now used are of more recent form than those in the Phenician and Samaritan alphabets: we will now go one step farther, and express our opinion, that in many of the characters, the Greek alphabet and the Etruscan (which, notwithstanding its independent name, is a mere offset from the Greek) generally present a more accurate picture of the original letters than those of the three former alphabets. That all these alphabets are identical in their origin, we will presently show in more detail. It is enough here to rely upon the evidence of Herodotus (v. 58), who expressly affirms (and he speaks from his personal examination) that the Ionians received their characters from the Phenicians, and that they were actually called Phenician. Now, there is no doubt that the inscriptions from which we have taken the Greek characters of our plate are older, at least, than either the Phenician inscriptions given in Boeckh, or the coins which furnished Mionnet with his characters. Hence, we may naturally expect to find at times in the oldest Greek characters traces of a higher antiquity and purer forms than in those which pass under the more venerable names of Hebrew, Phenician, and Samaritan. The mere wave then, we contend, was probably the original form of the *mem:* the initial or concluding stroke of the wave becoming, by a kind of flourish, longer than the others, leads to the so-called Etruscan and Greek forms in columns 6, 9, 14, 15, 16, 18. This long descending stroke takes a bend in the Samaritan and Hebrew characters towards the left, as was not unnatural in a language where the words run in that direction. By a comparison of the *gimel, nun, ayin,* and *pe,* and perhaps *caph,* with the corresponding letters in the other alphabets, the reader will perhaps be induced to ascribe the bottom strokes, which in these letters also run to the left, to the same accidental origin. This supposition is strongly confirmed by the fact, that the *caph, nun, pe,* and *tsadi,* when they are the final letters of a word, omit this appendage, and in its place have the perpendicular stroke merely continued in the same direction downwards, a little beyond its usual length. Our last example shall be from *ayin,* which is at once the name of a letter and the word which signifies an *eye.* The eye happens moreover to be a hieroglyphic character of the Egyptians, and therefore we cannot be surprised to find it among the Hebrew symbols. Nay, if we may believe Champollion, the picture of an *eye* in the Egyptian hieroglyphics was actually used at times for an *o,* exactly as *ayin* by the Hebrews. Now, though an eye might be represented at first with tolerable precision, it would, in the inevitable course of degradation, soon become a mere oval, or rather circle (for the eyes of animals are generally circular), with a small dot in the centre to mark the pupil. Such a character is actually found in our Greek series of alphabets, Plate II., Column 21, &c. The form afterwards lost its inserted point, and at times was corrupted into a lozenge or even a triangle. In Dr. Young's successive plates of parallel passages from Egyptian MSS. ('Encycl. Brit. Supp.' Pl. 78. N.) the reader may see an emblem, consisting, like our own, of a circle with a point in it, gradually wearing down in MSS. less and less carefully written, until it becomes at first a mere circle, and then something more like a triangle. After what has been said, we need hardly repeat that the Hebrew form appears again in a very corrupted state. A tail has been added, upon the principle explained above, and the careless writer (as in the Greek letter, Plate II., Column 20) has failed to make his circle meet at the top, an accident which may be also traced in the Hebrew *theth.* Indeed, the letters *ayin* and *theth* may be compared in nearly all their forms. Those who examine the changes of letters, will not be surprised, that what was at first an accident, became at last a fixed rule in the formation. We shall soon see other instances of this fact.

But before we proceed to an examination of the alphabets given in our plates, it may be useful to consider the distribution of articulate sounds among the vowels, liquids, and consonants. Attempts have been made by some writers to determine the number of distinct sounds which the human voice is capable of producing. A little consideration would have shown them that they were attempting to limit that which was essentially infinite. The vowel sounds all run into one another in a continuous gradation. The same is true of those modifications of sound which we call consonants, and likewise of the liquids. At the same time it is of course necessary that a limited number of symbols should be employed. Of these, some nations will employ more, some less, but few have ever made use of so many as thirty, unless indeed we include those alphabets which consist of syllabic symbols, and then, of course, the consonantal syllables will be multiplied in the proportion of the simple vowels. The vowel sounds are usually placed in the order *a, e, i, o, u,* such being their succession in the various alphabets of Europe and Western Asia; but if we wish to place them in that order which marks their relation to one another, we should write *i, e, a, o, u,* or in the opposite order, *u, o, a, e, i.* Mr. Willis, in two papers in the 'Cambridge Philosophical Transactions,' vol. i., for Nov. 24, 1828, and March 16, 1829, has shown by experiment, that the different vowel sounds may be produced artificially, by throwing a current of air upon a reed in a pipe, and that, as the pipe is lengthened or shortened, the vowels are successively produced in the order above given. When a door creaks, or a cat mews, we have experiments of the same nature, at least as regards the result, for in both these cases we may often detect the due series of the vowels. Indeed, the word *mew* would be more expressively written *mieaou.* In all these remarks we speak of the vowels as possessing those sounds which are common on the Continent, not those which are peculiar to ourselves; namely, *i* like *ee, e* like *ay, a* as in *father, o* as in *bone, u* as *oo* in *fool.*

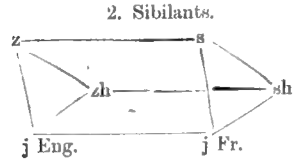
The liquids again should be written in the order *r, l, n, m,* beginning from the throat and advancing along the palate and teeth to the lips; or in the reverse order. For proof of this assertion, we need only ask the reader to sound the four letters, and at the same time note the parts of the mouth employed for each. The other letters have often been divided according to their organs: 1. The guttural and palatals, *g* (as before *a*), *k* (with *c, q*); *gh, ch* (as in the Scotch *loch*); *h,* with perhaps *ng, y,* and *wh.* 2. Dentals, *d, t; dh* (as *th* in *this*), *th* (as in *thing*); *z, s; zh* (like *ch* in *church*), *sh; j* (as in English), *j* (as in French). 3. Labials, *b, p; v, f,* and *w.* Perhaps the four last of those we have included among the dentals partake in an equal degree of the palatal character. In the above enumeration of the consonants, we have placed first in their respective series those commonly called the middle (or medial) letters *g, d, b;* then the *tenues,* or more delicate letters, *k, t, p;* and then the aspirates; but as each class presents two forms of the aspirate readily distinguished by the ear, and as these pairs of aspirates stand in the same relation to one another as the *medial* and *tenues,* we have throughout placed what we may perhaps call the middle aspirate before its delicate relative, namely, *gh* before *ch,* or χ; *dh* before *th; v* before *f.* Perhaps among the labials, *v, f, w* may be considered as aspirates; if so, they are still in their proper order. So among the six sibilants given after the dentals, it appears to us, that *z, ch,* and the English *j,* stand respectively to *s, sh,* and the French *j,* in the same relation of *medials* to *tenues,* and they are arranged accordingly. The letters *y* and *w* are *sui generis,* and are indeed intimately related to the vowels, having an affinity to the opposite extremities of the vocal series, *y, i, e, a, o, u, w;* and thus we may consider the commencement of the series as connected with the throat, and the termination with the lips. But although we have in the preceding enumeration appeared to limit the number of consonants, they are in fact, like the vowels, unlimited. Although an Englishman, for example, is satisfied with a single *t, l, f,* and *v,* he need not go far to find other nations whose wants are more extensive. An Arab has two modes of uttering a *t,* which to the ear of an ordinary European appear the same, and thus having what to him are two distinct results, he naturally employs two distinct symbols. A Pole, again, has two varieties of the letter *l.* So, also, in the comparison of different languages, it is well known that the sound of a German *w* approaches to, but is not identical with, an English *v;* and, in like manner, the Greek ϕ and Roman *f,* though treated by moderns as identical in power, are expressly distinguished by Quintilian. Nor can we stop at two varieties of the consonant. These are strictly, as we have said, infinite. In the production of a *t,* for example, the tongue may effect its contact with the palate either at the line adjoining the teeth or at a distance of an inch or more from this line. The two extremes give us those varieties of the consonant which, as just observed, are clearly distinguished by the ear of an Arab. But the contact might also be effected at any one of the intermediate points, and thus we have an imperceptible gradation from the palatal *t* to the dental *t.* Yet here again, as with the vowels, though the modifications of the consonant are without limit, it becomes a necessity to limit the symbols. We have a precisely parallel case in the colours produced by the prism, which pass by an imperceptible gradation from the one extreme to the other, and yet the names assigned to the colours are of necessity but few.

A tabular arrangement, in which the *medial, tenues,* and *aspirated* letters are placed in vertical columns, while those belonging to the same organ are collected in horizontal rows, affords a good view of them. But the parallelepipedon furnishes an arrangement superior to that of the square for the twelve related consonants given below; and for the sibilants, the angular points of the prism may be employed, while the vowels and liquids require nothing more than a simple line.

1. Consonants.

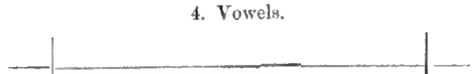


2. Sibilants.



3. Liquids.

4. Vowels.



In the preceding parallelepipedon, the three horizontal planes, beginning from above, represent the guttural or palatal, the dental, and the labial letters. The front vertical plane includes the aspirates; that at the back, the non-aspirates. The left vertical comprehends the medial letters; that on the right, the *tenues*. Every letter is, of course, at the intersection of three of these planes, and may be defined accordingly.

A distribution of the letters according to the actual nature of the sounds is of considerable use in the examination of those numerous euphonic and dialectic changes which occur not only in the polished language of Greece, but also in those languages which are inconsiderately called barbarous. But no single distribution will at once present to the view all the relations of the different letters. Not merely are the several letters in each of our horizontal, and to a certain extent also in the vertical divisions, interchangeable with their neighbours, but the twelve consonants arranged in No. 1 are in fact also related to the liquids, and even to the vowels. As these consonants extend from the throat to the lips, so do the liquids, and the vowels also, *y* and *i* being formed in the back of the mouth, *u* and *w* at the lips. In fact, the principle of lengthening the vocal pipe, which gave Mr. Willis the series of vowel sounds, is nothing more than what is done in the human mouth. To produce the first sound, we shorten the tube of the mouth; for the last, we extend it to its utmost length; and in intermediate degrees for the vowels, between the two extremes. In comparing therefore our ordinary consonants with the liquids and vowels, we find, as we might expect, *g* closely related to *y*, as our language in its older forms, and even its existing dialects, fully establishes. The intermediate *d* again has an affinity for *l*, *n*; and *b*, at the labial extremity of the consonants, is intimately related to *m*, *w*, and *u*, at the corresponding points of the other series. To make our views include the whole body of letters, it remains to be observed, in the first place, that had the nasal organ been considered, we should have had a series *m*, *n*, *ng* with their intermediate sounds depending partly upon the nose, and partly upon the lips, teeth, and palate respectively. In the Sanscrit alphabet, the series of guttural, palatal, lingual, dental, and labial consonants, have an *n* belonging to each class with a distinct symbol. That which belongs to the guttural series is a sound analogous to our *ng* in *ringing*. The nasal of the labial series is of course *m*. The other omission of our tabular view is the letter *h*, which, when pronounced at all, is a faint representative of the guttual aspirate *ch*. In the Hebrew alphabet, the names *cheth* and *heth* are given indifferently to the eighth letter, and the etymology of every language would supply examples of the connection.

Having endeavoured to arrange the letters of the alphabet upon some principle, we cannot pass over in silence the apparent confusion in the alphabets we have been speaking of, the Hebrew and the Greek. That the order observed in the latter is borrowed from the former, can scarcely admit of a question. For though the *vau* of the Hebrew has no corresponding character in the later Greek alphabet, it is yet well known that it once had such a correlative in the *digamma*, at least in power; and that the digamma was actually lost from the sixth place is proved from the gap at that point in the numerical use of the Greek alphabet, and the clumsy contrivance of filling it up by the symbol *ς*. The position of the letter F in the Roman alphabet is a proof in confirmation. The *tsadi* of the Hebrews can never have had a place in the Greek alphabet, but the following letter *koppa* most assuredly had, as is proved both by the existence of that letter in many of the older Greek inscriptions and the coins of Corinth, and no less decidedly by the insertion, as before, of a numerical substitute, which even retained the name of *koppa*. It may be observed, too, that the Latin *q*, of the same power and form, corresponds also in position; and the close connection between *koppa* and *q* is further confirmed by the fact, that as *q* is generally used solely before *u*, so *koppa* is rarely used except before *o*, as in the coins of Cos, Corinth, and Syracuse. The *schin* and *sin* of the Hebrew have in their own alphabet not merely an identity of form, except in the diritic points, but bear also the same numerical value, so that they must be considered as one in their origin. At *tau* the Hebrew series terminates, while the Greek adds first a *υ*, then a φ, a χ, a ψ, and an ω. That some of these did not belong to the early Greek alphabet is proved historically. The ω appears rarely before the year 403 B.C.; χ, ψ, and φ, were represented by ΦΣ, ΚΗ, ΠΗ, and *υ* or Υ appears to be only a variety of the *ayin*, to which it bears a strong resemblance in form. The letters *o* and *u* moreover in all languages are so closely related in power, that the one might almost supply the place of the other, as is actually the case in the Etruscan, which had a *u*, but no *o*. It is not therefore a very bold thing to assert that the early Greek alphabet terminated at the same point as the Hebrew. There is, however, a difficulty which should not be neglected. It has been a common assertion, that the old Greek alphabet consisted of only sixteen letters. But Pliny and Plutarch seem, in the first place, to be the sole authority for the statement; and the assertion of the former, that Palamedes, in the time of the Trojan war (!) added Θ, Ξ, Φ, Χ, and Simonides Ζ, Η, Ψ, Ω, is full of so many difficulties, that belief could not readily be given to him, even were there no counter authority. For upon what principle could the Greek letters have attained their present order, if they were introduced according to the chronological arrangement given by Pliny? But fortunately in the very passage of Pliny referred to (vii. 56, or 57), he gives another statement from Aristotle, differing from his own in several particulars, but it must be confessed not more satisfactory They mutually serve however to weaken the authority of each other In enumerating the sixteen letters, it may be observed that the long vowels Η Ω, the double letters Ζ, Ξ, Ψ, the aspirates Φ, Χ, Θ, are excluded by Pliny. In defence of Ω, Ψ, Χ, Φ we say nothing; but the character Η certainly did exist, not indeed as a long vowel, but as an aspirate. Thus with the *digamma*, the letter Η (*cheth*), and the *theta*, the old alphabet possessed a complete trio of aspirates: so erroneous is the notion that they should all be excluded. Lastly, as for Ζ and Ξ, the circumstance of their situation corresponding precisely to the *zain* and *samech* of the Hebrew would induce us to defend them, even at the risk of supposing (if such supposition be necessary) that, in their original power, they were not double letters. We do not however mean that the very characters existed, but that sibilants of some kind occupied their places. The precise correspondence of the Greek and Hebrew alphabets in the order and power and names of the letters, is an argument of much stronger weight than any testimony from such careless and late writers as Pliny and Plutarch.

But we are digressing too long from the question about the principle which governed the first arrangement of the Hebrew or old Greek Alphabet, if principle there be. Though we cannot satisfactorily account for the whole order throughout the twenty-two letters, there are certainly traces of some regularity in the arrangement We find first the simplest of the vowel sounds—simplest, because it requires neither retraction nor protrusion of the lips—followed by the three medials β, γ, δ, then another vowel, followed, with some irregularity indeed, by aspirates corresponding in order to the above consonants, *vau*, *cheth*, *theth*, no bad representatives of φ, χ, θ. Then again we have a vowel ι, followed soon after by three consonants related to each other, λ, μ, ν. Soon after we find a fourth vowel *o*, and after it, in a little disorder it must be allowed, *pi*, *koppa*, *tau*. It cannot well be a mere accident that the several classes of labials, palatals, and dentals occur so nearly together in the different parts of the series, and always in the same order. It will, perhaps, here be observed that in these remarks we are unintentionally confirming the assertion of Pliny and Plutarch about the sixteen letters, the more so as Plutarch (Symp. lib. ix. quaest. 3. § 2, Wyttenbach's ed. vol. iii. p. 1050) speaks of four quaternions. The chief objections to such an explanation of their statements consist in the difficulty of imagining a language to exist without a sibillant or *r*. But *th* approaches very nearly to the nature of a sibilant, and may have been used as one; while to many nations *r* and *l* admit of no distinction, so that one symbol is for them sufficient. Nay, the Latin had demonstrably at one time no *r*.

But we pause a moment to contribute a new item to the Curiosities of Literature. The theory here propounded, that the original Cadmeian alphabet consisted of four tetrads or quaternions symmetrically arranged, was originally given in the Penny Cyclopædia, in the year 1833 (Vol. I. p. 380, col. 2, &c.) In 1839 it appeared without acknowledgment in the 'New Cratylus,' pp. 99-101, with the one alteration, that in the second tetrad the vowel *i* was discarded in favour of a sibilant. The same writer again reproduced the theory in 1844, in his 'Varronianus' (pp. 188, 189); and when attention was called to this proceeding, he declared, on the word of a gentleman, that up to that moment he had not read the article, and indeed that on then referring to it, he found it to contain only a bungling approximation to his own theory. Lastly, in the second edition of his 'New Cratylus,' the same theory repeated in his text, p. 147, is accompanied by a note commencing:—"This organic arrangement of the alphabet has been more or less noticed by several philologers, of whom the earliest seems to have been the acute and learned Dr. Richard Lepsius, in his essay, 'über die Anordnung und Verwandschaft des Semitischen . . . . Alphabets.' (Zwei Abhandl. Berl. 1836.) Does the writer then mean to declare on the word of a gentleman that the year 1836 preceded the year 1833?

The accompanying plates require a few remarks in addition to what has been already said. The first plate contains alphabets running from the right to the left, a practice which seems to have been earlier than that which is now generally adopted. Herodotus tells us (ii. 36), that such, too, was the practice of the Egyptians, and his assertion is confirmed by a considerable number of the existing inscriptions, among which, however, some are found running in the opposite direction, and still more arranged vertically. The Etruscans, it is well known, turned their letters to the left, and there even exist specimens of Latin inscriptions with the same peculiarity. Among the Greeks, there were four modes of writing, one vertical (*κιονιδὸν* or *column wise*), and three horizontal, namely, one with the words running to the left; another, which soon prevailed over the rest, turned towards the right; and a third, in which the direction of the lines alternated, as in the course of a plough, from which idea, inscriptions of this kind are said to be written *βου-στροφη-δὸν*, or *ox-turning-wise*. This last method must have been much more convenient than our present broad sheet of letter-press, in which the eye, on arriving at the end of a line, requires a nice perception of a straight line to hit the commencing point again. The second and third plates give numerous specimens of the Greek alphabet, which are taken chiefly from Boeckh's great work, and the numbers written after the titles at the head of each column refer to the order of the inscriptions in that work.

The several inscriptions which have furnished these alphabets exist in the following forms:—

No. 14. In two flutings of a Doric column brought from the island of Melos, now in the Nanian Museum, but by some scholars much suspected.—No. 15. On a bronze tablet found in 1783 in Italy near Petilia, north of Policastro: it is in the Borgian Museum at Naples.—No. 16. On a vase discovered in a sepulchre near Corinth. (See Dodwell, ii. 196).—No. 17. On a votive helmet found in the Alpheius.—Nos. 18, 19. On a marble, now in the British Museum, No. 199.—No. 20. On a square marble base, near a temple of Apollo, in the island of Delos. (See Turnefort's 'Travels,' t. i. ep. vii. p. 360).—No. 21. On a bronze tablet dug up at Olympia and brought away by Gell in 1813.—No. 22. On a bronze helmet found in 1817, in the ruins of Olympia in the possession of Col. Ross.—Nos. 23, 24. Found at Delphi. (See Dodwell, ii. 509).—No. 25. On a small votive helmet found near

Coptic.

* The name of the 26th letter, and also its power, seem open to doubt, as the use of the same character in the letters 31—36 appears to imply that it has the sound of *ja*, or something similar. The Ethiopic is a syllabic alphabet, and it has a system of additional marks or modifications of the letters, marking a change of vowel, not unlike the points of the Hebrew. We have not thought it necessary to insert these.—*See* Ludolf.

Olympia, in the possession of Col. Leake.—Nos. 27, 28. Part of a hymn to Bacchus inscribed on an altar, which contains also a representation of a procession in honour of the god, in the Pembroke Museum at Wilton.—No. 29. From an epitaph in elegiac verse on those who fell in the first battle before Potidaea, B.C. 432. (Thucydides, i. 62). It was found in the plain of the Academy near Athens, and is now in the British Museum, No. 290. No. 30. The alphabet here given is that which came generally into use at Athens after the archonship of Euclides, 403 B.C. Specimens may be seen in the Elgin marbles of the British Museum, for instance in No. 305, the date of which is said to be 398 B.C.

The column No. 26 is from Mazocchi's folio on the Heraclean tablet. The Codex Alexandrinus, No. 36, is in the British Museum. [ALEXANDRINE CODEX.] The fourth plate relates to the Roman alphabets, including, however, what are often called, but without good reason, Saxon alphabets. These last characters were undoubtedly employed in writing Saxon, but they were the ordinary characters used during the same period for Latin, and were, indeed, thence borrowed for the former language; their identity besides with the preceding Roman letters, is very evident. Such of the Saxon characters as were not common to the Latin are placed below plate 4. The other alphabets have their names affixed, and also the titles and powers of the letters. The Coptic, Russian, Servian, Mœsogothic are evidently derived, with some exceptions, from the Greek; and the same is perhaps true, in a great measure, of the Ethiopic, Illyrian, and Runic.

In passing the eye along the various forms which the several letters have assumed, we shall see a strong similarity running throughout—from the Phenician through the Greek and Etruscan to the Latin; and nearly all the differences which do exist admit of explanation, if a few points be taken into consideration. The form of a letter must, in the first place, depend much upon the nature of the material upon which it is written, and of the instrument employed. On hard substances where incisions are to be made, straight lines will naturally prevail. When the letter is merely painted or inscribed upon a very yielding material, two or more inclined lines are apt to degenerate into

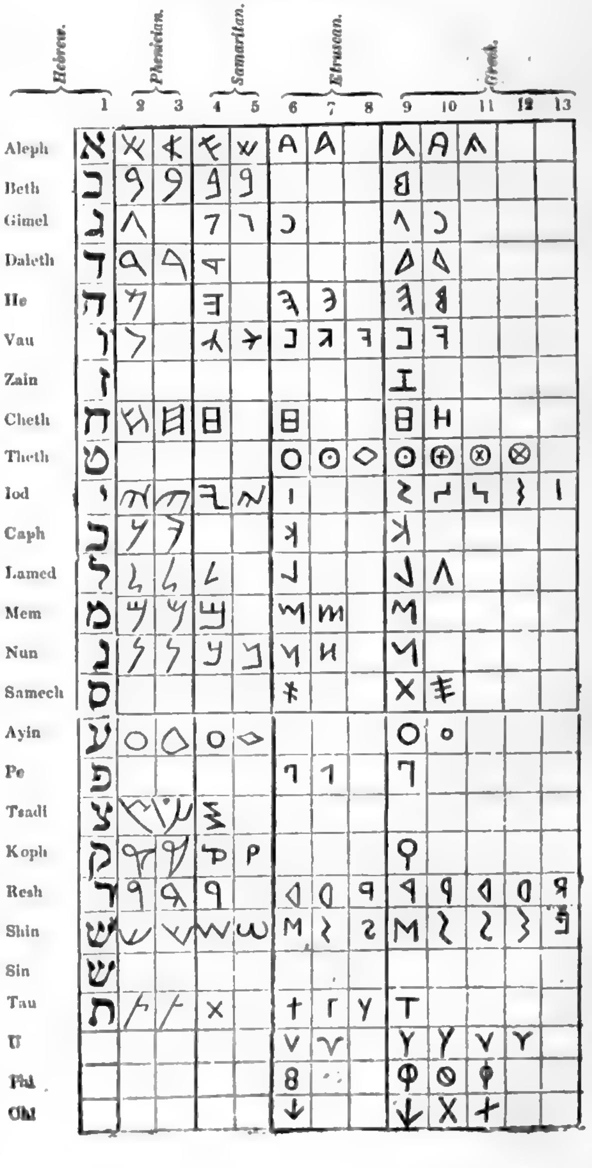
PLATE I.

Alphabets from right to left.



a single curve. Compare the forms of γ (the third letter) in columns 16 and 21; of δ (fourth letter) in 21, 23, and the Latin *D*; of ϵ (fifth letter) in 30, 33, and 34; of μ in 30 and 32; of π in 30, and the Roman *P* in 1, 2, 3, 4; of ρ in 20 and 21; of σ in 31, 32, and 33; of our own *u* and *v*, both derived from the same Latin character, &c. Again, in incisions the different lines which constitute a character will be generally of uniform thickness, but when a split reed or quill is employed, the strokes in one direction will be thick, in the other fine. Such has clearly been the origin of the existing Hebrew forms. A principle of corruption, not less powerful, is the desire of rapidity, which is most readily obtained by connecting the different parts of a letter together, so that the whole may be produced by one movement of the instrument, or, more strictly speaking, without raising the instrument from the surface. Thus the ϵ in 30 seems to be made by four separate strokes, such is certainly the case with the Roman letter in column 3; but that in 33 requires only two movements, and that in 34 but one. In the same way may be compared the forms of η in 36 and 37; of ξ in 30, 33, 35; of π in 37 and 38; of τ in 36 and 37, &c. But there may be several ways of effecting this object; a letter moreover may be commenced at different points, and hence arise double or more forms for the same letter, even at the same period: compare β in 37 and 38; ϵ in 34 with our own small running *e*, &c. This principle of rapidity carried a step farther leads to the connection of successive letters. In this way are formed what are called the cursive letters, which run on in continuous succession. Such modes of writing were no doubt common in very early times; and, as regards the Romans, we are not left to mere conjecture, as the British Museum contains an inscription of the kind on papyrus, which is referred to the second or third century. Lastly, a fanciful love of variety shows itself in all the works of man, and in none more than the arbitrary variations of letters, particularly those at the beginning and end of words. These several causes of change were more active, when nearly all writings were produced by the pens of individual writers. In modern times, the art of printing has tended strongly to create a unity of form, and will be the best protection against future change.

Having spoken thus generally of the alphabets given in the four plates, we will now remark upon each character in succession.

Of the letter A, one of the oldest forms, it appears to us, is in columns 10, 25, or 3. The greater part of the other forms arise from the different inclinations of the cross stroke, which in 7 runs from the extremity of one of the main strokes, and in 2, 4, and 11 is too much inclined even to meet the opposite side. No. 2 again is a mean between 4 and 1, and shows how the Hebrew form has originated. There was also an old Italian form of this vowel, which may be described as formed from the Π in 31, with a diagonal line running from the lower extremity on the right to the opposite angle; it was in fact the character in 14 or 16, with a square instead of a round or pointed top.—Of B it need only be remarked, that the Samaritan and Phenician

PLATE II.

Greek Alphabets.

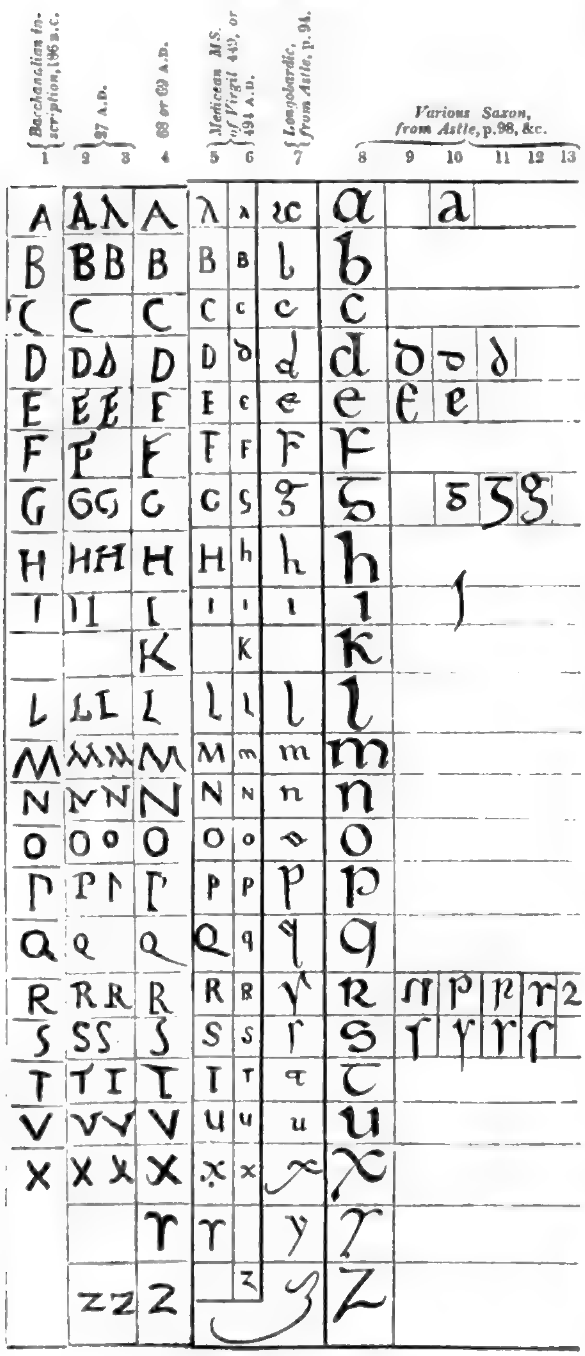
PLATE III.

Greek Alphabets continued.

forms show the progress of degradation between the Greek and the corrupted Hebrew. The forms of Γ are chiefly remarkable for the different positions of the angle which constitute the letter. The round form in 6, 10, and 16, is also found in the coins of the cities Gela, Agrigentum, and Regium. The third letter of the Latin alphabet has this form, and once possessed the same power. Hence, the oldest orthography of that language presents *macistratus*, *leciones*, for *magistratus*, *legiones*, and it is known that the common name *Caius* was pronounced *Gaius*, and indeed was so written by the Greeks. The form of the Hebrew *daleth* may be traced through the Samaritan from the Greek, in precisely the same way as the *beth*. The difference between the Samaritan or Phenician letters for *daleth* and those for

Plate IV.

Roman Letters.



Additional Saxon Letters.

ð dh; þ th; ƿ w.

beth consists solely in the lower stroke thrown out by the latter from the perpendicular, and the same is the case with the Hebrew letters; in both, the triangular or circular top has degenerated into a thick line.—The form of E in 10 is very anomalous and very rare. Of the other forms the Samaritan is again purer than the Hebrew. The next letter has been the subject of much controversy. The form in 8, 10, and 15, may perhaps be considered as the parent of all the rest; and again the Phenician has the advantage over the Hebrew, the form in 2 being intermediate between 4 and 1. The *zain* bears a faint resemblance to ζ of No. 9, which is the oldest form of that Greek letter, and from which the late forms are derived, upon the simple principle above mentioned, of completing a letter at one movement, and therefore substituting the diagonal stroke for the perpendicular.

The next letter has gone through violent changes, both in form and power. Its original power seems to have been a guttural *ch*, which would naturally wear away into an ordinary aspirate; or perhaps more correctly it may be stated, that its first power, as in the other letters, was syllabic, namely, *che*, which became *he*, and in the Greek language eventually only *e*. The two Hebrew names of the letters, *cheth*, *heth*, and the Greek form *eta*, all bear evidence in favour of such a supposition, and it would be difficult otherwise to account for the singular fact, that the same character H was at one time the Greek representative of an aspirate, afterwards of an initial *he*, and finally of a long *e*. In No. 26 of Plate II. H is the long vowel ē, and so in 30 of Plate III. and those which follow. In all the others which precede, it is an aspirated consonant. With regard to the various forms, the character in 3, 4, 6, 9, 22 being supposed to be the purest, No. 2 is half-way between the Hebrew on the one hand, and 18 on the other. But the Greek form did not stop here. When the letter H was appropriated as a vowel, the aspirate gradually lost its second pillar, until at last it appeared in the first of the two forms given in the Heraclean tablet, the second in that column being, as we have just stated, the representative of the long vowel. This form of the aspirate appears in many manuscripts above the initial letter of the word, but was eventually further corrupted into a mere comma, thus (ʽ). There exists, it should be stated, a story, that the Greeks derived their aspirate in a mode somewhat different from the above statement. The letter H, we are told, was cut into two parts, each consisting of a pillar and half the cross stroke; the first half being employed as an aspirate, the second as what they call a soft breathing, by which is meant simply the absence of an aspirate. A character to denote the absence of a sound is, it has been justly remarked, something new in alphabetic writing; and in fact it is now a common belief, that the soft breathing and its supposed representative are the mere creation of grammarians: at any rate, the supposed character for the soft breathing is found in no inscription whatever, and in no manuscript of any antiquity.—Of the next letter it need only be stated, that the Hebrew character is generally considered by modern Hebraists as a mere T, and it is often called *teth*.—Of the *iod* the Samaritan form seems even more perfect than the Greek in 9, 10, 11, 14, 15, 16, 17. The third of these, however, bears a close affinity to the Hebrew. The forms in 12 and 16 are gradually approaching the straight line, which afterwards prevailed.—The *kappa* in 21 is a mean between the more perfect in No. 9 and the Hebrew *caph*.—The next letter has a great uniformity throughout, the chief difference turning upon the different position of the angle as in the *gamma*; but it may be observed, that the forms in 27 and 28 closely approximate to the Phenician and Hebrew in 1, 2, 3.—Of μ and ν we have spoken before.—The *samech* and Greek ξ present many difficulties. Their forms, in the first place, have no similarity; the Greek letter is rarely met with in old inscriptions, as it was common to employ in its place the χ and σ, as may be seen in 23 and 29 (the $\kappa\sigma$ in the Nanian column is open to much suspicion.) The X given in 9, though found in Greek, is more common in Latin; yet even in this language the old inscriptions generally have XS, rather than X alone; so that it would seem that here, too, the X had originally the power of the Greek χ. The reason why the Greeks generally wrote XΣ rather than ΚΣ or ΓΣ, was most probably because the letter *sigma* has something of the nature of an aspirate, as Payne Knight contends. Upon the same principle they wrote ΦΣ for Ψ, not ΠΣ. (Column 29.)—The letter *ayin* is the subject of controversy, some calling it a nasal consonant, others a guttural, others a vowel *o*. The first and third assertions seem more at variance than they really are, for the close connection between the two sounds *n* and *o* is well marked in the Portuguese tongue in the pronunciation of such words as João, the representative of our John or Johann. The Romans, too, thought it enough to write Plato, where the Greeks wrote Platon. Lastly, if the vowel and liquid scales that have been given above be applied to one another, it will be found that the liquid *n* ought to have an affinity to the vowels *o* and *a*,* in the same way that the lip liquid *m* is related to *u* and *w*, and the palatal *l* (witness the *mouillé* sound of the French *ll*) to *y*, *i*, and *e*.—But, to proceed, the Hebrew *pe* has, it has already been observed, a stroke at the bottom which appears to have something of the nature of a flourish. Remove it, and the identity of the remainder with the Greek is self-apparent. The difference between the Greek Π and the Roman

* The connection between *a* and the final nasals is exhibited in the Ionic plurals of passive verbs, the double form of the accusatives of the third declension, and the Greek numerals δέκα, ἑπτα &c., compared with the Latin.

P is chiefly due to modern printers. The Greek had almost invariably its second leg much shorter than the first, and the Roman P very rarely had the circular bend completed so as to reach the main shaft. See the plates, and, above all, compare the Etruscan P in 7 with the Roman P in IV. 3.—The letter *tsadi* has no representative in the Greek alphabet, unless, indeed, it bear any relation to the Greek figure called *sanpi*, which, however, was never used, as far as it is known, for an alphabetic character; and secondly, even as a numeral, it does not occupy the place between π and *koppa*.—In the *koppa*, the Hebrew, or perhaps rather the Phenician, has a fuller and a more perfect form than the Greek; but be this as it may, the connection between them requires no comment.—If the ρ in 9 or 11 be the earliest form, the derivation of the rest is simple. The Hebrew has suffered the same injury as in *beth* and *daleth*, a comparison with which will remove all doubt. In 3, 13, and more fully in 22, 24, 27, we see the origin of the Roman *r*.—The original form of *shin* was perhaps as near the Hebrew as any of our characters; but, in fact, the difference between the *shin* in 1 and 4, and the Greek *sigma* in 9, 14, 15, 16, 17, 26, &c., or the Etruscan in 6, depends solely upon the altered position. The relative situation of the several strokes among each other is the same in both.—The next letter, *sin*, should perhaps have been omitted, as the difference between the power of *sin* and *shin* arises solely from the position of the point, which is near the right tooth in *shin*, near the left in *sin*. So completely are the two characters one in their origin, that they stand for the same number in the series of Hebrew letters.—The T in 6 would be a fit and proper parent for all the other forms. In the three characters, 1, 2, 3, 7, 8, the cross stroke has had an unfair preponderance to one side, as is the case again in our modern small character. In the Hebrew a little flourish has added to the difference.—The next letter, it has been already observed, seems to have grown out of the *ayin*. Its forms vary, but not unintelligibly. The modern *u* and *v* are, it has been already said, both derived from the Latin form, which had the double power of our consonant *w*, and our vowel *u*.—With regard to φ and χ, we find in 14 the double forms used before they were adopted; but unhappily the genuineness of this inscription is doubted.—Of the ψ, mention has been already made.—Ω brings us to the close; and it may be sufficient to observe, that among the forms given to this letter by Mionnet, in his work on ancient coins, one consists of an ordinary *o* lying upon a horizontal straight line. This has led to the notion that the letter was thus originally formed to mark a long ō, and, in confirmation of this notion, the letter H, as written in No. 9, was appealed to, which it was contended was formed in like manner from the letter E, with a perpendicular stroke on the right. The form of ω, in 32, would appear to be made up of the letter *ayin* or *o* repeated, precisely as our own *w* has its form as well as name from a repetition of *u* or *v*. The letter ω as well as η were not used in public documents at Athens until the year 403 B. C., when Euclid was Archon, but it must not be supposed that the letters were then invented, for, as Payne Knight has observed, the ω appears on the coins of Gelon, who died 478 B. C., and the η on very ancient coins of the Regians. Still in early times it was the ordinary practice to use *o* and ε for both long and short vowels.

In forming a table of the real Roman characters, there is some difficulty from the circumstance, that nearly all those who report ancient inscriptions take the liberty of using modern characters. Of those given in plate 4, the first is from the fac-simile of the Baccanalian inscription given by Drakenborch in the seventh volume of his 'Livy;' the date of which is fixed at 186 B. C., by the names of the consuls given in the decree. This inscription is in the Cæsarean Museum at Vienna. The second and third columns are from an inscription given by Maffei, in his 'Istoria Diplomatica,' p. 38, and here the date is fixed to the year 27 A. D., in the reign of Tiberius, by the names of the consuls, M. Crassus Frugi, L. Calpurnius Piso. Column 4 is from the same work of Maffei, p. 31, and belongs to the year 68 or 69, as is determined by the mention of the Emperor Galba. Both these inscriptions are of very coarse execution. Fac-similes of some very ancient inscriptions are also to be seen in the works on Herculaneum and in Muratori. The characters of the Medicean manuscript of Virgil, preserved at Florence, are taken from Burmann's engraved specimen, in the first volume of his edition of that author, p. xxxvi. of the preface. The remaining alphabets of that plate are from Astle's 'Origin of Writing.' The separate alphabets, beginning with the Coptic and ending with the Runic, are chiefly from the French 'Encyclopædia.'

The Roman alphabet requires but little comment. It has been seen how completely it agrees with the Greek. In the order of the letters the only violent difference consists in the insertion of the G after F, but what place could be better suited to it than the position of Z, a character which had no correlative in the Latin series? Our modern grammars, indeed, give both *y* and *z*, but Suetonius tells us indirectly that the Roman alphabet terminated at *x*, for the Emperor Augustus, he observes, employed a peculiar cypher in his papers. For the letter *a* he wrote *b*; for *b*, *c*; and so on, until for *x* he wrote *a* or *aa*. Some commentators, indeed, scandalised at the ignorance of Suetonius in not knowing his own A, B, C, have substituted *z* for *x* in the above passage. But, in fact, there is not a single Latin word that contains either *y* or *z*. Modern printers have further increased the Latin alphabet by giving in two instances double characters where the Romans had but one. The letter I of the Romans, besides its power as a vowel, represented also the closely-allied sound of our consonant Y, or the German J. When it is used with this consonantal power, modern printers have taken the liberty of substituting the character J, and modern readers have aggravated the error by giving it the sound of that English letter. Thus the Latin word IVGVM is now printed and pronounced *jugum*, instead of *iugum* or *yugum*, so as to destroy the close similarity of the word to the corresponding English term, *yoke*. Again, the Roman letter represented by *v* in inscriptions, and by *u* in the round form of manuscripts, has suffered the same fate. As a vowel, it has *u* for its character in modern books of Latin. But the Romans, as we have already stated, also employed it as a consonant, equivalent to our *w*. In this case the printer has preferred the sharp form *v*, which has again misled the modern reader as to the sound. When pronounced correctly, the Latin words *vespa, vastare, ventus*, bear a close analogy to our own terms *wasp*, to *waste, wind*. The letter K, though it became unnecessary when the third character was changed from a *gamma* to C, is a genuine member of the Roman alphabet, though often excluded from school grammars. What we have said leads to the result that the Roman alphabet had twenty-one letters, and this number agrees with the statement in Cicero ('Nat. Deor.' ii., 37 or 93).

It would be rather an amusing subject of inquiry, to trace to their source the remarkable differences in the magnitude of our modern small characters, some rising above, others descending below the general line. The first attempts of certain letters to shoot out into an undue extent may be seen in several parts of Plate IV., and we will leave the development to any reader who may be disposed to pursue it. It is but right to state further that the remarks we have made, and the alphabets we have given, are by no means sufficient to enable any one to read ancient manuscripts. Independently of the varying forms of letters, there are numberless contractions, which can only be learned by long practice.

ALPHONSINE TABLES. [ALONSINE.]

AL-SIRAT (that is, literally, 'The Path'), in the theology of some of the Mohammedans, is the name of a bridge extending over the abyss of hell, which must be passed by every one in order to enter paradise. It is described as being narrow, like the edge of a sword. Some, it is said, will pass it with the rapidity of lightning, others with the swiftness of a horse at full gallop, others like a horse at a slow pace, others still slower, on account of the weight of their sins, and some will fall down from it, and be precipitated into hell.

ALT, in music (from the Latin *altus*, high), that part of the scale beginning with F, the fifth line in the treble clef, and ending at E, the third leger, or additional, line above the same clef.

ALTA, in music (Italian 'high'), generally used in addition to the word ottava, as 'ottava alta,' an octave higher; 'più,' more, being by custom omitted.

ALTAR, an erection to offer sacrifice upon. The first altar mentioned is that set up by Noah, to offer sacrifice when he quitted the ark; and throughout the history of the Jewish patriarchs, altars are continually said to have been erected by them, in different places, as circumstances rendered it expedient. These seem to have been built of earth, or unhewn stone, like the altars which God commanded Moses to raise: *Exod.* xx. 24, 25. But when the Jewish law was given, the right of raising altars and offering sacrifice was no longer left common to all men; but one altar of burnt-offering, at which alone victims were slain, was made for the whole nation, and the priests, as ministers for the nation, offered sacrifice upon it for all. This in the first instance was constructed of wood, covered with brass, and always followed the ark, while the ark was migratory; but when Solomon built the temple, he placed a stone altar, with a brazen hearth, in the court before it. The Jews had two other altars, one solely appropriated to burning incense, called the altar of incense; the other called the altar of shew-bread, because loaves were placed upon it, and changed every Sabbath; which stood in the interior of the temple.

We constantly meet in the Bible with the expression of the 'horns of the altar.' Some suppose that these were really the horns of animals; others that they were merely projections at the corners. One use of them is obvious: victims might be conveniently bound to them. *Psalm* cxviii. 27. But horns were an emblem of power and authority throughout the east; and probably they were also meant to indicate the greatness of him to whom the altar was sacred. The altars of the Greeks and Romans had sometimes horns also, to which animals were fastened, and to which those who fled thither for protection used to cling. It was an act of impiety to force such persons away. This belief in the sanctity of places was adopted by the Roman Catholic Church, which, in the season of its temporal power, largely bestowed the privilege of sanctuary upon favourite churches and convents. [ASYLUM.]

A sort of natural religion seems to have pointed out the tops of hills and groves, as the fittest spots for altars. The pagan nations which surrounded the Jews were especially addicted to worshipping in high places; and it was hardly possible to prevent the Jews themselves from falling into this habit. "They also built them high places, and images, and groves, on every high hill, and under every green tree." 1 *Kings* xiv. 23. Passages of the same import occur continually in the Jewish Chronicles. The northern nations of ancient Europe worshipped in the thickest shade of their forests. The ancient Persians, as Herodotus tells us (I. 131), made no temples, nor statues, nor altars, but worshipped the deity on the tops of the mountains.

The altars of the Greeks were of three sorts: those dedicated to the heavenly gods (βωμὸς), were often structures of considerable height; those of demi-gods and heroes were low and near the ground (ἐσχάρα); and those of the infernal deities (if such may be called altars) were trenches sunk in the ground (βόθρος, λάκκος). They may again be divided into three classes, those for burnt-offerings (ἔμπυρος): those on which no fire was used, which were (ἄπυροι), meant for offerings of fruit, meal-cakes, &c.; and those on which fire might be used to consume vegetable productions, but no blood was spilled (ἀναίμακτοι), the altar: when dedicated to either of the latter classes, it was often nothing more than a raised hearth or step. Each temple usually had two altars, one in the open air before it, for burnt-offerings; another before the statue of the god to whom the building was sacred. Altars were often erected where there was no temple. The Greek altars were usually square, sometimes circular, or triangular. They were often made of marble, and elegantly sculptured.

The Roman altars and rites of worship much resemble the Greek. We must distinguish between *altare* and *ara*. The former, as is indicated by the syllable *alt*, signifying high, was an elevated structure, used only for burnt-offerings, and dedicated to none but the heavenly gods: the latter might belong either to the heavenly, or infernal gods, or to heroes. The Romans, however, like the Greeks, dug trenches (*scrobes*), into which they poured libations to the infernal gods. *Ara* seems to be the general term, and is used by Virgil as including *altare*;

En quatuor aras,
Ecce duo tibi Daphni, duoque altaria Phœbo.—*Ecl.* v. 65.

From *altare* comes the English word altar, which by the Roman Catholic church is used in its proper sense, to denote an erection on which sacrifice is offered, it being their doctrine that the mass is a sacrifice. Applied to the communion-table of an English Protestant church, the word is used metaphorically, or rather is misplaced; for the English church teaches the sacrament of the Lord's Supper to be no sacrifice, but merely a symbol. Altars were in England taken down, and wooden tables substituted, by royal command at the bishop's visitations in 1550; again set up at the commencement of the reign of Mary, and finally removed at the beginning of the reign of Elizabeth. Several of them, however, which escaped destruction, still remain in churches in various parts of England, and some of them are fine examples of the art of the period.

ALTAR-PIECE. We are accustomed in this country to give the name of Altar-piece only to paintings on sacred subjects placed over the altar at churches; but in earlier times the same name was given to small elaborately worked productions in gold and silver, and other metals, connected with the offices of religion. The exhibition of Mediæval Art at the rooms of the Society of Arts in 1850 contained many such specimens, in which much skill was often shown both by the artist and the artificer. One was an altar-piece of silver, partly gilt, enriched with scrolls and garlands, and enclosing enamels and gems.

ALTERATIVES, a word signifying 'things that produce a change.' Under this head are comprehended those medicines which do not produce any immediate or very perceptible effect, but which gradually bring the body from a diseased to a more healthy state. They seem to act in removing unhealthy conditions of the system, much in the same way that a drop of water hollows a stone, not by its violence, but by frequently falling. They are generally given in small and frequent doses, and, even when given in large doses, they are often repeated. The former mode of administering them is employed when they are powerful medicines, the latter when less active. Out of almost every class of medicines some one may be used as an alterative—its claim to be so regarded depending less upon its natural powers than upon the manner in which these are modified, so as to effect a particular purpose. Thus by diminishing the dose, or combining them with other medicines, some of the most powerful drugs we possess are capable of being employed as alteratives, and made to produce effects exactly opposite to what they do when given alone, or in large doses. Ten grains of ipecacuanha, for example, taken with some fluid into the stomach, will speedily cause a feeling of sickness, followed by vomiting—three or four grains will cause a feeling of sickness and loss of appetite, though not actual vomiting—while one-quarter or one-half a grain taken about an hour before each meal for several days in succession, will be found greatly to increase the appetite, and improve the digestion. Yet even ten grains of ipecacuanha, if taken along with two of opium, will not produce any obvious effect on the stomach, but, if the patient be kept warm in bed, will cause a profuse flow of perspiration.

Many of the forms or preparations of mercury, even the most active and poisonous, when given in very small doses, neither prove purgative nor destructive to life, but, on the contrary, often produce signal benefit, relieving the patient from many complaints which rendered his days miserable, or even threatened to shorten them. Nor is the most dreaded of the mineral poisons—arsenic itself—incapable of contributing to the restoration of health, since we see it now make the shivering ague cease, and at another time cause the agonising headache to depart.

Others which are less active may be given in very large doses, as sarsaparilla, and similar articles.

The variety of agents which may be used as alteratives must convince us that they cannot all act in the same way, and that their beneficial effects cannot be attributed to the same cause. Most of them appear to act upon the secretions and excretions—either by increasing their quantity or altering their quality. In many parts of the body, but particularly along the course of the alimentary canal, are situated glands, the duty of which is to elaborate from the blood certain fluids containing salts and other principles, which are primarily useful in keeping moist the surfaces over which they flow, and often secondarily useful in effecting changes in the matters with which they come in contact, as the saliva with the food, as soon as it is received into the mouth, and the bile with the chyle, upon its passage out of the stomach. These, then, are secretions. The kidneys and skin are organs by which fluids are separated from the blood, serving as vehicles for the removal from the system of salts and other principles no longer useful, the retention and accumulation of which would soon prove hurtful, and ultimately fatal. These are termed excretions:—that of the kidneys being of no primary or secondary use, while that of the skin keeps this covering moist and pliant,—states necessary for its answering the objects of its existence.

The preservation of a due proportion in the quality and quantity of these secretions and excretions is essential to the maintenance of that equilibrium, that fair and equal, or harmonising play of all the organs of the body, when, feeling no weight or oppression in any part, a man readily says he *is well*. The disturbance of this balance gives rise to various degrees of uneasiness and ill-health; states to which the French apply the expressive term—*malaise*.

The functions of secretion and excretion being rather vital than chemical processes, they are greatly dependent upon the state of the nervous system. This, again, is only perfect when the blood is of a proper quality; and this last is beholden for its excellence to the thorough performance of digestion, for which a due supply of nervous energy is required.

As all these functions act and re-act upon each other, it matters but little which of them is the first to fail in contributing its part to the general welfare, as all in time suffer; but the functions of secretion and excretion, perhaps, soonest show a falling off, and soonest attract the attention of the patient. He awakes with a dry tongue, and observes that the secretion from the kidneys is less in quantity and more highly coloured than natural, or excessive in quantity and pale, or he perceives that the skin is dry and harsh, or bloated.

To remedy these states, alteratives are often employed. Small doses of some mercurial, alone, at night, or with rhubarb and soda during the day, or small quantities of ipecacuanha, will often relieve the dryness of the mouth. A little common salt taken immediately on waking will also remove it. With this view a little bacon has often been recommended at breakfast—the benefit being due to the salt, not the bacon.

The removal of the depraved and unhealthy secretions from the intestinal canal, where they are apt to linger, causing uneasiness to the patient, and by the unpleasantness of his breath rendering his presence disagreeable to others, is best effected by a course of gentle purgatives. The frequent repetition of too powerful purgatives is to be reprobated, as often occasioning disease of the inner coats of the alimentary canal. After these, some strengthening medicine, as bark or iron, will generally be useful, especially if the nervous system be out of order, owing to much mental exertion, or protracted night-watching. At this stage of the treament, exercise and travelling, change of scene and pursuit, are of much service; or a visit to some watering-place; for the mineral springs, having the saline ingredients very minutely divided, may be considered as nature's alteratives.

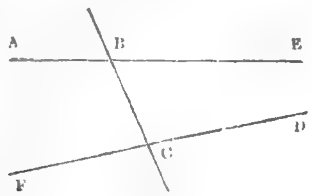
Where the skin is much affected, exercise of a regulated kind, such as that practised by trainers, may prove useful, as the diet is at the same time strictly attended to. Indeed, a partial or complete change of diet is often the most effectual alterative we can employ.

But neither medicines nor a strict plan of diet should be begun or continued without the advice of a competent judge. It is in such cases that persons are most apt to undertake the cure of their own complaints, and, either by using inefficient means, allow them to get rooted in the system—or, by employing the *nostrums* and secret, but often dangerous, combinations of *quacks*, become a prey, in their purses and persons, to ignorance and fraud.

The explanation of the functions of the system, and the action of remedies, already given and hereafter to be given in this work, are by no means intended to enable the patient to dispense with the assistance of his medical attendant, but to prepare him to receive the full benefit of that assistance, by enabling him to understand something of the principles on which his treatment is conducted, and thereby to teach him how he may co-operate with his physician in rendering it effectual.

ALTE'RNATE. In geometry, angles are said to be alternate which are made by two lines with a third, on opposite sides of it, as A B C and

B C D, or E B C and B C F. If two lines be parallel, the alternate angles made by a third line with them are equal.



In algebra, those terms of a proportion are said to be alternate which are separated from one another by another term; thus, in the proportion

2 is to 4 as 8 is to 16,

2 and 8 are alternate terms, as also 4 and 16. If alternate terms be rendered consecutive, and consecutive terms alternate, the proportion still continues; thus,

2 is to 8 as 4 is to 16.

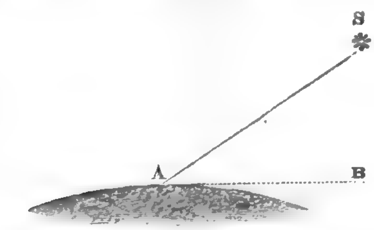
This proposition is the sixteenth of the fifth Book of Euclid, and is referred to by the Latin word *alternando*, or by the English words 'by alternation,' or 'alternately.'

ALTHIONIC ACID (HO, $C_4H_5S_2O_7$?) is produced when oil of vitriol in great excess is heated with alcohol until olefiant gas begins to be evolved. It has the same composition as sulphovinic acid, but its compounds differ in crystalline form. It is highly probable that the althionates are compounds of the sulphovinates and isethionates.

ALTIMETER is the name which the Rev. E. L. Berthon gave to a measuring instrument patented by him in 1850. It is a somewhat complicated contrivance, intended to measure the altitude of the sun, moon, or a star. There are two glass bulbs, one containing mercury and the other spirit, and placed in connexion with each other by vertical and horizontal tubes. A telescope is attached, through which the object is viewed. The vertical tubes are graduated; and the heights at which the two fluids adjust themselves in these tubes, when the telescope is directed obliquely upwards, is made to indicate the altitude or angle of elevation of the object viewed, by a particular arrangement of the several parts.

ALTISSIMO, in Music, is the scale which commences with F, the octave above the fifth line in the treble.

ALTITUDE, from the Latin *altus, high*, may be rendered by the English word *height*. This being the case, we should have referred it to the English word, if the term were not particularly reserved in astronomy to signify, not the *length*, but the *angle* of elevation. Thus, if A be the position of a spectator on the earth, and A B the line on the



horizon, which is drawn towards the point directly under the star S, the angle B A S is the altitude of the star. For other less common applications of the term, see HEIGHTS.

The altitude of the pole is the geographical latitude of the place of observation, and remains the same throughout the twenty-four hours: the altitudes of the stars and sun change with the diurnal motion; being nothing when they rise and set, and greatest when they are on the meridian.

The altitude of a star is directly observed at sea with the SEXTANT; and the uses which are made of such observations may be seen in the following mathematical propositions, into the proofs of which we cannot enter here.

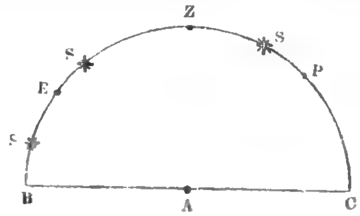
1. When the latitude of the place is known, the time of day may be found from one observation of the altitude of the sun or a star; or conversely, if the time of day be known, the latitude may be found from the observation.

2. When neither the time nor the latitude is known, both may be found by observing any two altitudes of the sun or a star, and noting the time which elapses between the observations; but it is most convenient to observe one altitude first, before a star comes to the meridian, and then wait for the time when the same star comes to the same altitude on the other side of the meridian. Or if the latitude be very nearly known, a more accurate approximation may be simply made by the above method.

3. If the star be one of those which never sets, the latitude of the place is the half sum of its greatest and least altitudes.

In all that precedes, it is supposed that the star is *known*,—that is, that its right ascension and declination are known; and certain corrections must be applied to the observed altitude, for which see DIP; PARALLAX; REFRACTION.

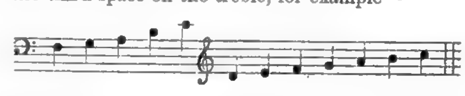
In fixed observatories on land, the altitude of stars, or rather their zenith distances, which are what the altitudes want of ninety degrees, are observed with the mural or the transit circle [CIRCLE, ASTRONOMICAL; TRANSIT]; but only when the stars are on the meridian. Let A be



the place of the observer, C and B the north and south points of his horizon, P the north pole, Z the zenith, C P Z B the meridian, arcs of which may be made to represent angles at A, and S the star on the meridian, whose altitude, B S, or C S, according as it is south or north of the zenith, or its *complement*, the zenith distance, Z S, has been observed. Then, E being a point in the equator, and P E being equal to Z C, both being ninety degrees, take away the common part Z P, and E Z is equal to P C, the latitude of the place. And E S, or the star's declination, is E Z diminished by Z S, if the star passes the meridian above E, or Z S diminished by E Z, if the star passes below E. If the star passes between the zenith and the pole, the declination E S is the sum of E Z and Z S. That is, the declination of a star is the difference between its observed zenith distance and the latitude of the place, if the star passes south of the zenith, or the sum of the same quantities, if it passes between the zenith and the pole. In the first case the declination is *north*, if the latitude be greater than the zenith distance; *south*, if the zenith distance be greater than the latitude: in the second case, it is always north.

In this way, with a number of minute precautions for the sake of accuracy, catalogues of the declinations of stars are formed, by observation of their altitudes, or, which amounts to the same thing, of their zenith distances.

ALTO, in Music, is the highest natural adult male voice, or countertenor, the usual compass of which is, from F the fourth line in the bass, to C the third space on the treble, for example—



Alto is also one name of the instrument called in England the tenor, and in Italy the viola.

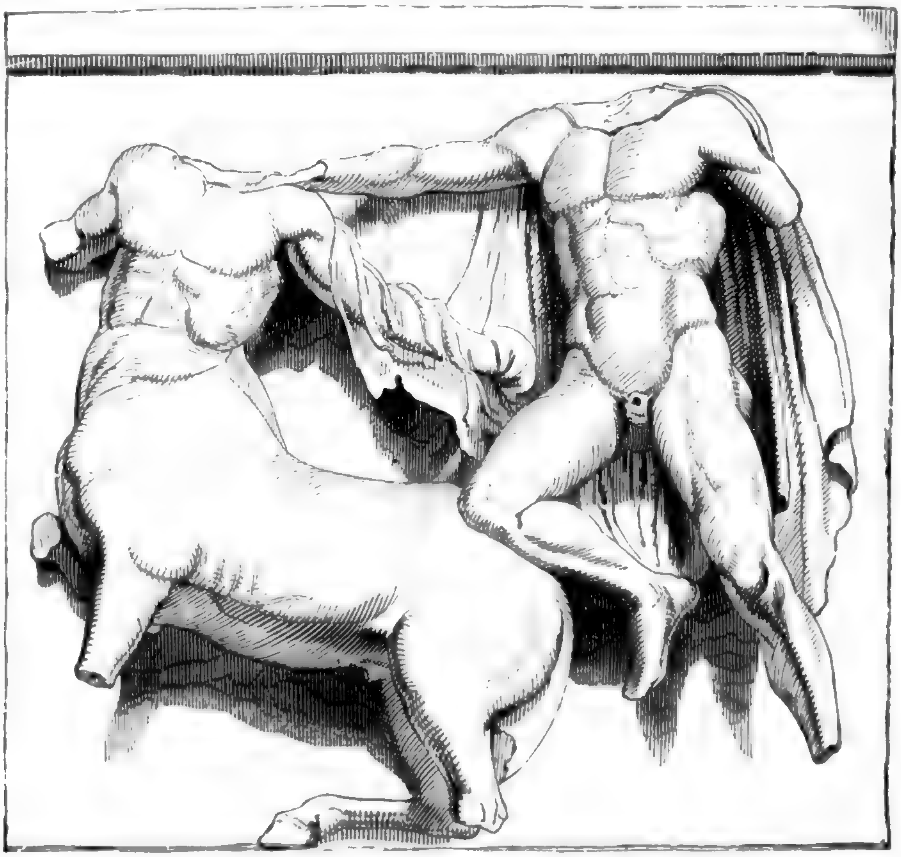
ALTO CLEF, in Music, a name of the C clef, when placed on the third line; more commonly, in England, called the countertenor clef. [CLEF.]

ALTO-RILIEVO, BASSO-RILIEVO, MEZZO-RILIEVO. The Italian term alto-rilievo is commonly applied to any work of sculpture connected more or less with a plane surface or back-ground, and in this general sense is opposed to insulated detached figures, or sculpture in the round. In its more particular meaning, alto-rilievo, or high relief, is usually appropriated to figures which are not only rounded to the full bulk, but have generally some portions of the figures quite detached. Basso-rilievo, low or flat relief, on the other hand, has only a very slight projection from the ground; and mezzo-rilievo (a style between the two), although sometimes rounded to a considerable bulk, has no part entirely unconnected with the plane surface or ground. A more accurate definition of the styles to which these designations refer will result from the explanations that follow. The terms used by the Greeks and Romans to distinguish these kinds of relief cannot perhaps be determined with complete accuracy; and it may be here remarked, that those writers are mistaken who suppose the word *Toreútike* (*τορευτική*) to have been applied by the Greeks exclusively to alto-rilievo, since Heyne, and indeed other writers before him, have proved that the term was appropriated to carving, and chiefly chasing in metal, in any kind of relief. The Latin word corresponding with it is *cælatura*. The Greeks seem to have employed the term *anaglypta* to denote works in relief in general; and the *ectypa sculptura* of Pliny (xxxvii. 10) also means work in relief. The term *glypta* (from *γλύφω, to cut into, to hollow out*), with other words formed from the same verb, appears to denote sculpture in the concave sense, intaglio. Herodotus, in a passage of his second book (cap. 138), where we have little doubt that he is speaking of the sunk Egyptian reliefs (which will be mentioned in another part of this article), couples a word formed from the verb (*γλύφω* with the word typus (*τύπος*): typus itself (perhaps) always means a work in relief properly so called. (See Herod. iii. 88; Cicero ad Atticum, i. 10.) Italian writers of the time of Vasari, it appears, used the term mezzo-rilievo for the highest relief, basso-rilievo for the less prominent, and *stiacciato* for the flattest or least raised. Whatever the origin of this kind of sculpture may have been, and there is no doubt of its being very ancient, an idea will be best formed of its style, as practised by the Greeks, by supposing it to be derived from the partial insertion of a statue in a perpendicular plane. Alto-rilievo is often literally nothing more than this. Applied however to a flat surface, the disposition of the limbs and the actions of the figure become necessarily more or less parallel with that surface, in order sufficiently to adhere to it. The attitude is thus, in a certain degree, adapted or selected. In inserting or embedding a figure in a flat ground, it is obvious, that although it may be buried *less* than half its thickness, as in alto-rilievo, it cannot be buried *more*, nor indeed (the structure of the figure strictly considered) quite so much, without ceasing to present the real boundary or profile of the form. In the less prominent kinds of rilievo it is therefore still required that the outline should present the real form, and this principle in its further application excludes, in a great measure, the *unreal* forms of perspective and foreshortening, which would suppose that the objects are no longer parallel with the surface on which they are displayed. Attempts at foreshortening must in most cases fail to satisfy the eye. The work can only be seen in front, and the appearance it presents is therefore required to be at once intelligible, for no uncertainty can be removed by an inspection from another point of view, as in walking round a statue. The bulk, or thickness, need not however be real, provided it appear so. The compression of the bulk, which constitutes the various degrees of mezzo- and basso-rilievo, thus follows the compression or flattening of the action, the characteristic of alto-rilievo. Lastly, the modifications of which this branch of sculpture was susceptible, were adopted, as we shall see, according to the varieties of light, situation, dimensions, and use.

The Greeks, as a general principle, considered the ground of figures in relief to be the real wall, or whatever the solid plane might be, and not to represent air as if it was a picture. The art with them was thus rather the union of sculpture with architecture than a union of sculpture with the conditions of painting. That this was founded on the most rational principles will be evident from a few simple considerations. The shadows thrown by figures on the surface from which they project at once betray the solidity of that surface. In the attempt to represent, together with actual projection, the apparent depth of a picture, or to imitate space, figures which are supposed to be remote are reduced in size; but although thus diminished in form, they cannot have the strength of their light and shade diminished, and if deprived of shadow by inconsiderable relief, they cease to be apparent at all when the work is seen from its proper point of view—that is, at a sufficient distance; having no distinctness whatever in the absence of colour, but by means of light and shade. In short, the art, thus practised, has no longer an independent style, and only betrays its inferiority by presenting defects which another mode of imitation can supply. A passage in Vitruvius proves that the ancients were not unacquainted with perspective; and the same author states that perspective scenic decorations were first employed by Agatharcus at Athens, in the time of Æschylus. However greatly the science may have been advanced by the moderns, this may be sufficient to prove that the absence of perspective in Greek bassi-rilievi was not from an absolute ignorance of its principles, but from a conviction that they would be misapplied in sculpture.

In carefully keeping within the limits, however narrow, which defined the style of rilievo, the great artists of antiquity failed not to condense into that style the utmost perfection compatible with it, while the various applications of the works suggested abundant variety in their treatment and execution. The British Museum contains unquestionably the finest existing specimens of this branch of sculpture in the rilievi which decorated the Parthenon, or Temple of Minerva, at Athens. We have here to consider the judicious adaptation of their styles for the situations they occupied; but in regard to their general excellence as works of imitation, it may also be well to remember that these sculptures were the admiration of the ancients themselves. Seven hundred years after they were produced, Plutarch spoke of them as "inimitable works."

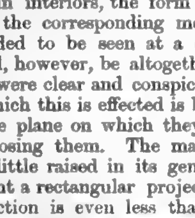
The figures which adorned the pediment are separate statues, although in their original situation, casting their shadows on the tympanum, they must have had the effect of bold alti-rilievi; the circumstance of their



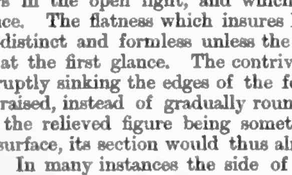
being thus completely detached must have given the greatest distinctness to their forms, and as they occupied the highest part of the building, their gigantic size and complete relief made them fully effective at a considerable distance. The sculptures which adorned the metopes, or spaces between the triglyphs, are in alto-rilievo. Those in the British Museum, representing combats with Centaurs, were taken from the south side of the building: the subjects were varied on the other sides, but they mostly related to the warlike exploits of the Athenians. It has been well observed, that the subjects of combats, usually chosen for the metopes in Doric temples, afforded opportunities of composing the figures so as to produce diagonal lines, which effectually distinguished the groups from the architecture, and at the same time had the effect of reconciling the vertical forms of the triglyphs with the horizontal lines of the epistylium and cornice. The compositions in question all fully occupy the space destined for them, and are calculated, from their treatment and relief, to produce the utmost possible effect. Those works which received the open light were thus boldly relieved from their ground to insure the masses of shadow which make them conspicuous: the principle, applicable to external architecture, that projection commands shade, was thus extended to external decorations; and care seems to have been taken to keep the light on the figures as unbroken as possible, especially as the whole series of metopes occupying the external frieze was more or less crossed by the shadow of the cornice. This precaution necessarily limits the attitudes, for many actions equally natural with those adopted would have projected shadows on the figure itself, thus tending to confuse the forms. A statue which can be seen from various points, and sometimes in various lights, might thus be unfit as to its composition for that intelligible display in one view and under a constant light which rilievo requires. On the principle that high relief is fittest for the open light, the rilievi of the temple of Phigaleia, which are also preserved in the British Museum, are bold in their projections. These works adorned the interior of the cella, but as the temple was hypæthral, or lighted from the open sky, the principles of external decoration were applicable. Had the temple been imperfectly lighted, a flatter kind of relief would have been preferable, and this leads us to consider the style of basso-rilievo, properly so called, the most perfect existing specimen of which is also in the British Museum. It adorned the external wall of the cella of the Parthenon, within the peristyle or colonnade, and was consequently always in shade: the strongest light it could ever receive would probably be the reflection from the pavement below when the sun was highest; but as reflected lights are uncertain, and may proceed from various points, the sculptures in question were calculated to be equally distinct in whatever direction the light was thrown. Their great elevation, and the peculiar angle at which they were seen, owing to the narrowness of the space between the exterior columns and the cella, may also be mentioned in considering the reasons which rendered projection unadvisable. That this confined view was not however the sole reason, may appear from the bold relief of the Phigaleian marbles, which, in the interior of the narrow cella of the temple they adorned, must have been seen on the side walls at a very inconsiderable distance compared with their height. The Phigaleian temple was built, according to Pausanias, by Ictinus, the chief architect of the Parthenon; and although the sculptures are inferior as works of art to the generality of Greek specimens, their style of relief is precisely the point where the architect may be supposed to have influenced their execution.

As projection commands shade, so flatness commands light, and the flattest relief is hence fittest for an invariably dark situation. The same principle is observable in architecture in the treatment of mouldings in interiors, the form and projection of which differ materially from the corresponding members in the open light, and which are intended to be seen at a distance. The flatness which insures light would, however, be altogether indistinct and formless unless the outlines were clear and conspicuous at the first glance. The contrivance by which this is effected is by abruptly sinking the edges of the forms to the plane on which they are raised, instead of gradually rounding and losing them. The mass of the relieved figure being sometimes very little raised in its general surface, its section would thus almost present a rectangular projection. In many instances the side of this projection is even less than rectangular; it is undercut, like some mouldings in architecture which require to be particularly distinct, and thus presents a deeper line of shade. But if the figure can thus command distinctness of outline, notwithstanding the inconsiderable light it may receive, it is obvious that its lowness or flatness of relief will in such a light greatly aid its distinctness: above all, this contrivance gives the work thus seen in an obscure situation the effect of rotundity. Indeed, it is a great mistake to suppose that the flat style of relief was intended to appear flat, and it is a great mistake to apply it in situations, as in the open air, where it must appear so, and be indistinct besides. The conventions of the arts are remedies, adopted in certain situations and under particular circumstances, and are supposed to be concealed in their results: their ultimate resemblance to nature, and their successful effect in those circumstances, are the test of their propriety and necessity. The absence of all convention in alto-rilievo (as opposed to the flat style), thus fits it for near situations, if not too near to expose it to accidents. The excellent sculptures which decorate the pronaos and posticum of the Temple of Theseus,

Lateral portico of the Parthenon.



End portico of the Temple of Theseus.

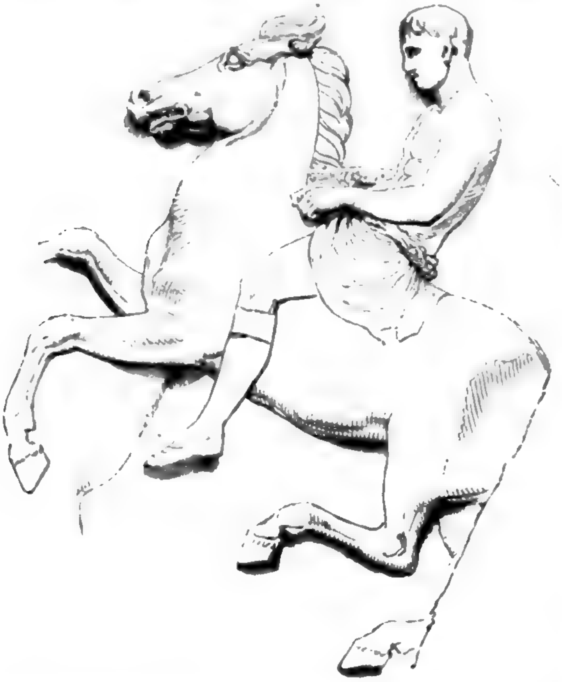


although under the portico, are in bold relief. They were not only nearer the eye, and seen at a more convenient angle than the flat rilievi of the cella of the Parthenon, but the reflected light which displayed them would necessarily be much stronger.

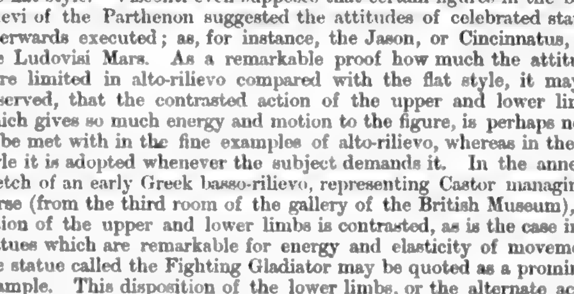
It is also to be remembered that only the end porticoes, where the sculpture could be more conveniently seen and was better lighted, were decorated with rilievi; the side walls of the cella were unornamented, and undoubtedly bold relief would have been less adapted for them. The Temple of Theseus was built about thirty years before the Parthenon; and it is not impossible that the satisfactory effect of the flat rilievi on the cella of the latter might have suggested a similar treatment, or some modification of it, in the Temple of Theseus, had it been erected later. It may be observed in general, that alto-rilievo can seldom be fit for interiors, not only from its liability to accident, but from the difficulty of displaying it by the full light which it requires. A superficial light, especially if in a lateral direction, necessarily throws the shadows of one figure on another. Instances of this occur in some of the palaces in Rome where works of sculpture have been injudiciously placed. A room, for example, lighted in the ordinary way, will have its walls (at right angles with that occupied by the windows) adorned with a frieze in considerable relief; the figures nearest the light consequently project their shadows so as to half conceal the next in order.

The conditions of proximity and distance, as well as the quantity and direction of light, were carefully attended to by the Greek sculptors, and suggested new varieties of relief. The end of the art, as far as relates to execution, is accomplished when the work is distinct and intelligible at the distance whence it is intended to be viewed. Hence the conventions which are intended to correct the defects of distance, of material, want of light, &c., are evidently unnecessary where the work admits of close inspection. The style of mezzo-rilievo, which in its boldest examples presents about half the thickness of the figure, is, on many accounts, least fit for a distant effect: the figure is nowhere detached from its ground; at a very little distance its shadowed side is lost in its cast shade, and its light side in the light of its ground; the outline, in short, soon becomes indistinct, but the semi-roundness of the forms is directly imitative, and thus again the absence of all conventional treatment fits the work for near situations. The style was preferred to alto-rilievo in such cases, as the latter would have been more liable to accidents, and would besides in some measure deform the outline or profile of any object which is circular in its plan. The figures which adorn sculptured vases are thus in mezzo-rilievo: these works probably ornamented interiors where any indistinctness in their distant effect or in an unfavourable light might be obviated by closer inspection. Two specimens may be seen in the second room of the Gallery of Antiquities in the British Museum. The celebrated Medicean and Borghesan vases, the finest known examples, are in like manner ornamented with mezzo-rilievo. The same consideration applies to all works, however unfit for a distant effect, which can, or in their original situation could, only be seen near. Even the mixed style of relief in the sculptures which occupy the internal sides of the Arch of Titus at Rome, would hardly be objected to, since the objects represented are distinctly seen, and can only be seen, at the distance of a few feet. The style of semi-relief (much purer than that of the Arch of Titus) adopted by Flaxman in front of Covent Garden Theatre, may be defended on the same principle, since the utmost width of the street is hardly a more distant point than a spectator would naturally retire to in order to see them conveniently. The still flatter style which has been introduced on the exterior of several buildings in London cannot, however, be defended on any grounds, and there can be no doubt, from the reasons adduced, that bold relief is generally fittest for the open light. The mezzi-rilievi on the miniature choragic monument of Lysicrates (casts from them are in the British Museum) may be admitted to have been fitly calculated for their situation because they must have been seen near; but there was in this case an additional consideration to be attended to; the building is circular, and alto-rilievo was avoided in order to preserve the architectural profile: on the other hand, the frieze of the small Temple of Victory, which was rectangular, was adorned with alti-rilievi; and in this case it appears that they did not even extend to the angles. The objections to sculpture on monumental columns will be obvious from these considerations; it has been observed, that in attempting to preserve the architectural profile, as in the Trajan column, and its modern rival in the Place Vendôme at Paris, the sculpture thus slightly relieved soon becomes indistinct, nor indeed would this indistinctness be obviated at a considerable height even by alto-rilievo, the figures being necessarily small, while the evil is only increased by substituting the dark material of bronze for marble.

We proceed to consider the varieties of style in this art as affecting composition. In rilievo, and in sculpture generally (a colourless material, or a material of only one colour being always supposed), it is evident that shadow is the essential and only source of meaning and effect. In works placed in the open air, and visible in one point only, as in the case of alto-rilievo, a certain open display of the figure is generally adopted; the shadows, or rather the forms which project them, are so disposed as to present at the first glance an intelligible and easily recognised appearance, and the impossibility of changing the point of view, or changing the light, as before observed, limits the attitudes more than in a statue, and, as will also appear, more than in a basso-rilievo. For in the latter, however distinct the outline is in which the chief impression and meaning of the figure reside, the shadows within the extreme outlines are in a great measure suppressed; it is, in fact, by their being so suppressed that the general form becomes so distinct. This is also the case when one form is relieved on another; it will be seen that the nearest object is very much reduced and flattened in order that its shadow may not interfere with the more important shadows of the outlines on the ground, and hence it may often happen that the nearest projection is least relieved. It will thus be evident that, owing to this power of suppressing the accidental shades and preventing them from rivalling or being confounded with the essential ones, the choice of attitudes becomes less limited, and



many a composition which in full relief would present a mass of confusion from its scattered and equally dark shades, may be quite admissible and agreeable in basso-rilievo. Accordingly the attitudes of statues, which are generally unfit for alto-rilievo, frequently occur in the flat style. Visconti even supposes that certain figures in the bassi-rilievi of the Parthenon suggested the attitudes of celebrated statues afterwards executed; as, for instance, the Jason, or Cincinnatus, and the Ludovisi Mars. As a remarkable proof how much the attitudes were limited in alto-rilievo compared with the flat style, it may be observed, that the contrasted action of the upper and lower limbs, which gives so much energy and motion to the figure, is perhaps never to be met with in the fine examples of alto-rilievo, whereas in the flat style it is adopted whenever the subject demands it. In the annexed sketch of an early Greek basso-rilievo, representing Castor managing a horse (from the third room of the gallery of the British Museum), the action of the upper and lower limbs is contrasted, as is the case in all statues which are remarkable for energy and elasticity of movement: the statue called the Fighting Gladiator may be quoted as a prominent example. This disposition of the lower limbs, or the alternate action in which one of the arms would cross the body, never occurs in alto-rilievo, because the shadow of the arm on the body or of one of the



lower limbs on the other could then no longer be suppressed, as it is in this case, but would rival the shadows of the whole figure on the ground. Among the metopes of the Parthenon, the Phigaleian marbles, and the alti-rilievi of the Temple of Theseus, there is not a single instance of the contrasted action alluded to; while in the two latter examples, the contrary position, or open display of the figure, repeatedly recurs, even to sameness. It must however be admitted, that this open display of the figure, although not presenting the most energetic action, is as beautiful as it is intelligible, and hence the finest exhibitions of form were quite compatible with the limited attitudes to which the sculptors thus wisely confined themselves. The objections which compelled this limitation being however entirely obviated in basso-rilievo, by the power of suppressing at pleasure the shadows within the contour, we find the fullest advantage taken of the latitude which was thus legitimately gained.

A better example cannot be referred to than the flat rilievi already mentioned from the cella of the Parthenon. (See the next Illustration.) The subject represents the Panathenaic procession, and although no perspective diminution is admitted, several equestrian figures are sometimes partly relieved one upon the other. The confusion which results from the number of similar forms in the repetition of the horses' limbs, as well as in the actions of the horsemen, must be admitted; but perhaps the subject is thus better expressed than by a simpler arrangement, and this treatment contrasts finely with the single figures. In a procession of horsemen moving two or three abreast, we are at once aware that the figures are similar, and the eye is satisfied, as it would be in nature, not in searching out each individual figure as if it had a separate principle of action, but in comprehending the movement and the mass, for one indicates the whole. Where the figures thus cross each other they are treated as a mass; the outline of the whole group is distinct and bold, being more or less abruptly sunk to the ground, but the outlines which come within the extreme outline are very slightly relieved. In short, the principle here applied is precisely the same as that observable in a single figure in the same style of relief: the outline of the whole form is distinct, or rather most distinct where it is most important, and the internal markings are seldom suffered to rival it, but are made subservient to this general effect. The relative importance of the objects is, indeed, the only consideration which is suffered to interfere with this principle: thus loose drapery is sometimes slightly relieved on the ground, while a significant form is now and then strongly relieved even on another figure. In comparing the slight varieties of treatment in these rilievi, it is to be remembered that the end porticoes were a little wider than the lateral colonnades. It is undoubtedly to this circumstance that the difference of treatment alluded to is to be referred; the figures in the end friezes are more separated from one another, and consequently somewhat more relieved than the compact processions on the side walls.

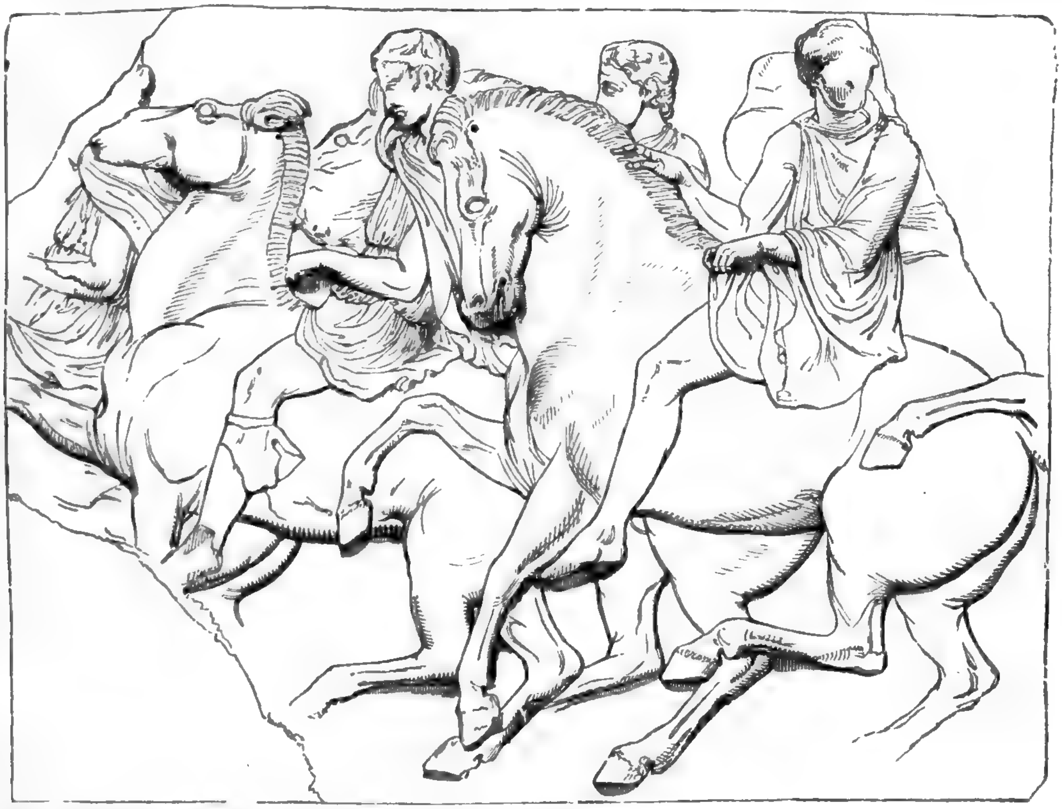
The fact that these bassi-rilievi, as well as most of the sculpture of the ancients, were partially painted, has been purposely left out of the account, because the very contrivances resorted to are calculated to supply the absence of colour. The custom in the best age of Grecian art of painting architecture and sculpture may be defended or excused elsewhere; it may be however here remarked, that while the ancient sculptors added colour after having employed every expedient which could supply its want, the moderns, in altogether rejecting it, often fail to make use of those very conventions which its absence demands.

It appears that the principle of suppressing the relief within the extreme contour which, with the strong marking of the outline itself, mainly constitutes the style of basso-rilievo, was employed by the ancients in works of considerable relief, in interiors, in particular lights, and probably at some distance or elevation. The real projection which works thus strictly belonging to the class of bassi-rilievi may sometimes present, points out the essential difference between basso and mezzo rilievo: a work, even if in very slight general relief, which has the parts that are nearest the most relieved, belongs to mezzo-rilievo; while a work which has the nearest parts least relieved, constitutes basso-rilievo, whatever its general projection may be. In the former, the outline is thus less apparent than the forms within it; in the latter, the outline is more apparent than the forms within it. The early Greek and Etruscan rilievi, which, however flat, have the nearest parts the fullest, while the outline is scarcely, if at all, rectangular in its section, have thus the principle of mezzo-rilievo. They are even fitted for near inspection, and cannot be said to present any unsatisfactory convention; for the bulk, however really thin, is proportionate in its relief, and is so far directly imitative; inasmuch as the eye consents to a diminished scale of bulk as easily as to a diminished scale of height, while the indistinctness of the outline has the effect of rounding the form. Such works are besides fitted for near examination, because they can scarcely command any shadow. Various specimens may be seen in the British Museum.

The antique vases of Arezzo were ornamented with figures in this kind of relief. Certain silver vases mentioned by Pliny were of the same description. The Egyptian intaglio, for so it may be called, rather than rilievo, belongs to the same style. The Egyptian artists, instead of cutting away the background from the figure, sunk the outline, and slightly rounded the figure, on the principle of mezzo-rilievo, within. Thus no part of the work projected beyond the general surface, and the architectural profile was preserved. There are, however, many very ancient examples at Thebes of figures slightly relieved from the ground, somewhat on the principle of basso-rilievo as practised by the Greeks,—that is, with the nearest parts least relieved, and with outlines rectangular in the section. Many of them, probably, in their original situations, and when the buildings were entire, ornamented interiors. Some Persian rilievi, in the British Museum, approach the same style. The Egyptian rilievi were painted in brilliant colours, and would have been ineffective in the open light without such an addition.

The distinctions of the three styles of relief, according to the Greek examples, may now be thus recapitulated. In the highest relief, however decided the shadows may and must of necessity be, on the plane to which the figure is attached, the light on the figure itself is kept as unbroken as possible, and this can only be effected by a selection of open attitudes; that is, such an arrangement of the limbs as shall not cast shadows on the figure itself. In basso-rilievo, the same general effect of the figure is given, but by very different means: the attitude is not selected to avoid shadows on the figure, because, while the extreme outline is strongly marked, the shadows within it may be in a great measure suppressed, so that the choice of attitudes is greater. Mezzo-rilievo differs from both: it has neither the limited attitudes of the first, nor the distinct outline and suppressed internal markings of the second: on the contrary, the outline is often less distinct than the forms within it, and hence it requires, and is fitted for, near inspection. Its imitation may thus be more absolute, and its execution more finished, than those of either of the other styles.

Most of the coins of antiquity are executed on the principle of mezzo-rilievo; and though often far bolder in this relief than modern works of the kind, are treated in a mode corresponding with their minute dimensions, which require close examination. The outline thus gradually rounds into the ground, and is never abruptly sunk, while the nearest parts are most relieved. Thus, conventional methods are always wanting in works that admit of close inspection, where the eye can be satisfied without such expedients. The comparatively strong relief of the heads on the ancient medals is again a contrivance for their preservation, and presents a new variety in the style of rilievo. Coins are exposed to friction, and the forms they bear are thus liable to be soon effaced. The earliest means adopted to prevent this was by sinking the representation in a concavity, in which it was thus protected. This plan was soon abandoned, for obvious reasons; and the method ultimately adopted was that of raising the least important parts most. Accordingly, the parts that are rubbed away in many fine antique coins are precisely those which can best be spared; the hair has generally a considerable projection, so that the face and profile are often perfectly preserved after 2000 years: a better specimen cannot



be adduced than the celebrated Syracusan coin representing the head of Arethusa or Proserpine. In addition to the propriety of its style, this head is remarkable for its beauty, and is classed by Winkelmann among the examples of the highest character of form.

The ordinary style of mezzo-rilievo was also used for gems, and indeed for all works in this branch of sculpture which required close inspection, and needed no conventional contrivance. A flat style of relief, which is sometimes observable in cameos, was adopted only for the sake of displaying a subject on a different coloured ground; the layers of colour in the stone employed, generally the sardonyx, being very thin. The difference of colour in the ground has, however, the effect of giving roundness to the figures relieved on it, as if, their whole effect becoming apparent, the internal markings disappeared. The figures on the Portland Vase are treated on this principle; and as it was intended to imitate a precious stone (for which indeed it was at first taken), the thinness of the outer layer of colour is also imitated. Such works, however, reduced to one colour in a cast or copy, are totally wanting in effect and style. The impressions from intagli, or engraved gems, which were used for seals, are never in the flat style of relief, but however slightly raised, are on the principle of mezzo-rilievo as above defined. The gems of Dioscorides, the finest of antiquity, are in mezzo-rilievo, and often of the fullest kind; as for instance, the heads of Demosthenes and Io, and the figures of Mercury and Perseus. The same may be observed of other celebrated gems, such as the Medusa of Solon, the Hercules of Cneius, &c. It is supposed that the same artists who engraved on gems, and who frequently inscribed their names, also executed the dies for coins. The latter are among the finest antique works of art; but of the many thousand existing specimens there is but one which bears the name of the artist, namely, the coin of Cydonia in Crete, the inscription on which proves it to be the work of Nevantus. It was observed, that in the antique coins, the least important parts are the most raised, and the reasons which dictated this practice limited the view of the head to the profile; but as the same reasons were no longer applicable in engraved gems, the impressions from which could be renewed at pleasure, the front, or nearly front view of the head was occasionally attempted, and seems to have been preferred by Dioscorides and his school. The head of Io before mentioned, considered with reference to this specific propriety of its style, as well as with regard to its general merits, is placed by Visconti in the first class of antique engraved gems. Thus the most skilful artists of antiquity seemed to consider the style of any one of the arts to consist chiefly in those points which were unattainable by its rivals. It may be here observed too, that they generally limited their representation to the most worthy object, namely, the human figure, when the dimensions on which they were employed were necessarily confined. Indeed, the principles of imitation itself were, as it were, condensed, and true character often exaggerated as the materials appeared less promising; so that the genius of ancient art is as conspicuous in minute engraved gems as in colossal sculpture.

Mezzo-rilievo of the fullest kind was also fitly employed (as well as alto-rilievo, when in situations not exposed to accidents) to ornament tombs and sarcophagi. These works, placed in the open air, decorated the approaches to cities, as the sepulchres were always without the walls. The Appian Way was the most magnificent of these streets of tombs in the neighbourhood of Rome, and must have exhibited, literally, thousands of sepulchral monuments. Though generally the work of Greek artists, and often interesting from being copies of better works now lost, the haste and inattention with which such prodigious numbers were executed, tended to degrade the style of their sculpture. In these rilievi, even in the better specimens, buildings and other objects are occasionally introduced behind the figures, thus approaching the spurious style of relief in which the effects of perspective are attempted to be expressed: a great variety, of various degrees of excellence, are to be seen in the British Museum. The greater part of what are called Roman bassi-rilievi are of this kind, and may be considered a middle style between the pure Greek rilievo and the modern Italian. It was from antique sarcophagi, fine in execution, but with these defects in style, that Niccola da Pisa, in the 13th century, first caught the spirit of ancient art. Many of the works from which he is believed to have studied are still preserved in Pisa. D'Agincourt gives a representation of one of the best. In imitating the simplicity of arrangement, and, in a remote degree, the purity of forms which these works exhibited, the artist was not likely to correct the defects alluded to, which had been already practised in Italy and elsewhere. Various degrees of relief, background figures and objects, and occasional attempts at perspective, are to be found in the works of the Pisani and their scholars, yet their works, which are to be regarded as the infancy of Italian art, and which undoubtedly are rude enough in workmanship and imitation, are purer in style than those of the succeeding Florentine masters, who attained so much general perfection in sculpture. The rilievi of Donatello are mostly in the style called by the Italians *stiacciato*, the flattest kind of mezzo-rilievo, according to the definition before given, which he probably adopted, as he worked in bronze, from the facility of casting; yet in such a style, commanding little distinctness from its inconsiderable projection, he introduced buildings, landscape, and the usual accessories of a picture. But this misapplication of ingenuity was carried still farther by Lorenzo Ghiberti, in the celebrated bronze doors of the baptistery, or church of San Giovanni, at Florence, which exhibited such skilful compositions, in which the stories are so well told, and in which the single figures are so full of appropriate action. In these works the figures gradually emerge from the *stiacciato* style to alto-rilievo. They are among the best specimens of that mixed style, or union of basso-rilievo with the principles of painting, which the sculptors of the fifteenth century and their imitators imagined to be an improvement on the well-considered simplicity of the ancients. In these and similar specimens, the unreal forms of perspective buildings, and diminished or foreshortened figures, which in pictures create illusion, when aided by appropriate light and shade and variety of hue, are unintelligible or distorted in a real material, where it is immediately evident that the objects are all on the same solid plane. Even Vasari, who wrote when this mixed style of rilievo was generally practised, remarks the absurdity of representing the plane on which the figures stand ascending towards the horizon, according to the laws of perspective; in consequence of which, "we often see," he says, "the point of the foot of a figure, standing with its back to the spectator, touching the middle of the leg," owing to the rapid ascent or foreshortening of the ground. Such errors, he adds, are to be seen "even in the doors of San Giovanni." Lorenzo Ghiberti, like other Florentine sculptors, first learnt the practice of his art from a goldsmith, and the designs of the artists who competed with him for the honour of executing the doors of San Giovanni were submitted to the judgment of goldsmiths and painters as well as sculptors.

The taste of the Florentines in basso-rilievo was thus greatly influenced by the prevalence of a style most applicable to the precious metals, in which a general sparkling effect is best insured by avoiding uniformly violent relief, which projects considerable shadows, and especially by avoiding unbroken flatness. The background is thus filled with slightly relieved distant objects, so as to produce everywhere a more or less roughened or undulating surface. The same end seems to have been attained in the antique silver vases, by the introduction of foliage. The style continued to be practised with occasionally greater absurdities than those before alluded to, and perhaps less redeeming excellence, till the close of the last century. The sculptor Falconet says of the antique bassi-rilievi, that "however noble their composition may be, it does not in any way tend to the illusion of a picture, and a basso-rilievo ought always to aim at this illusion." He leaves no doubt as to the literal meaning he intends by citing the Italian writers who applied the term *quadro* indiscriminately to picture and basso-rilievo. Sculpture in this country was indebted principally to Flaxman for the revival of a purer taste in the application of basso-rilievo to architecture. In works of decoration, intended to be executed in the precious metals, in which, as before observed, moderately embossed and general richness of surface is so desirable, in order to display the material as well as the work, he, however, united his own purity of taste and composition with an approach to the mixed style of relief practised by the Florentine masters, who, in this branch of sculpture, perhaps never equalled his shield of Achilles.

ALUM. ($KO, SO_3 + Al_2O_3, 3SO_3 + 24$ aq.) or ($NH_4O, SO_3 + Al_2O_3, 3SO_3 + 24$ aq.) Alum as met with in commerce is a double salt, one of the constituents of which is sulphate of alumina, and the other either sulphate of potash or sulphate of ammonia. These two descriptions of alum are distinguished respectively by the names *potash* alum, and *ammonia* alum. Potash alum is occasionally met with as a natural product in volcanic districts. It is there formed by the action of sulphuric acid upon lavas and trachytes containing potash and alumina. Under these circumstances it is found at Auvergne in the South of France, in Sicily and the adjoining volcanic islands, also in the neighbourhood of Naples, at the Grotto di Alume (Capo Miseno), and at Solfatara. The alum forms an encrustation on the surface of the volcanic rocks, and being dissolved in water, it is recrystallised after the mechanical impurities have been removed by subsidence. It is then sent into the market as *Roman* alum.

Such natural alum constitutes, however, but a very small proportion of that used in the arts. For several centuries alum has been made in this country, from deposits found at Whitby in Yorkshire, and at Hurlett and Campsie near Glasgow, and known as *Alum Schist* or *Alum Shale*. This material contains, amongst other ingredients, alumina, iron pyrites, and a bituminous or coaly matter. The following is the process employed for obtaining alum from this schist:—

1. A thin layer of brushwood is laid upon the ground, and on this alum schist is piled in a pyramidal form to the height of 90 or 100 feet. The brushwood is then ignited, and the combustion gradually communicates itself to the coaly matter of the schist, which is present in sufficient quantity to afford heat enough for the calcination of the whole mass. Great care is taken to cause the combustion to proceed very slowly, otherwise the mass would become partially fused, and the objects of the operation be defeated. From one to two years are therefore required for the burning of one of these heaps. During the calcination the bisulphide of iron (iron pyrites) is decomposed, and converted at the expense of atmospheric oxygen into protosulphate of iron and free sulphuric acid, the latter uniting immediately with the alumina of the shale to form sulphate of alumina. These chemical changes may be thus expressed:—

$$\underbrace{3FeS_2}_{\text{Iron pyrites.}} + O_{21} + \underbrace{Al_2O_3}_{\text{Alumina.}} = \underbrace{Al_2O_3, 3SO_3}_{\text{Sulphate of alumina.}} + \underbrace{3FeOSO_3}_{\text{Protosulphate of iron.}}.$$

2. When the whole mass has been exposed to the necessary temperature, and has again become nearly cold, it is sprinkled with water from time to time, so as to moisten it thoroughly without interrupting the circulation of air through its interstices; the object being to oxidise the protosulphate of iron and to convert it as far as possible into insoluble basic persulphate. A certain portion of the iron, however, still remains as neutral persulphate, but this probably suffers double decomposition with the silicate of alumina in the shale, producing soluble sulphate of alumina and insoluble silicate of iron. The mass is now lixivated with water in stone cisterns, when sulphate of alumina nearly free from persulphate of iron dissolves out.

3. The aluminous liquor thus obtained is now concentrated by evaporation until it attains a density of about 1·4. This operation is performed in brickwork cisterns lined with lead, thirty-six feet long, six feet wide, and two or three feet deep, heated by the reverberatory flame from a furnace placed at one end and fed with highly bituminous coal. Much soot is deposited in the pans, but it subsides, leaving the liquor above it clear. The latter is then run off into tanks and allowed to cool.

4. The cool concentrated liquor is now ready for conversion into alum, which is effected by adding to it a sufficient quantity of a saturated solution of sulphate of potash or sulphate of ammonia; in the former case potash alum is produced, whilst in the latter ammonia alum is the result. As sulphate of ammonia is now, in almost all localities, a more abundant and consequently cheaper salt than sulphate of potash, it has almost entirely superseded the last-named salt in the alum manufacture, nearly all the alum now met with in commerce being ammonia alum. As alum is far less soluble in cold water than sulphate of alumina, it is precipitated in the form of a granular crystalline powder, termed "alum-meal," when either of the sulphates just mentioned is added to the concentrated solution of sulphate of alumina. Thus the alum at the moment of its production becomes separated from a number of other salts, such as the sulphates of iron, lime, magnesia, &c., which remain in solution, and the remaining operations have for their object the rendering of this separation more complete by removing the impure liquor from the interstices of the alum-meal, which is effected by washing the latter twice with small quantities of cold water and then recrystallising it from a boiling saturated solution. The latter operation is performed in vessels termed *roaching casks*, which consist of a sufficient number of staves, six feet long, lined with lead, and fitting tightly around a circular flagstone, four to five feet in diameter, which thus forms the bottom of a cask or vat; the staves are held together by strong iron hoops, which can be tightened or relaxed at pleasure by screws joining their extremities, thus permitting the casks to be put together or taken to pieces with great facility. Into these casks the boiling saturated solution of alum is run; and as it cools most rapidly where it is in contact with the staves, a thick crystalline encrustation of alum soon attaches to the sides of the cask, and in three or four days becomes strong enough to retain the interior liquor without the assistance of the staves, which are accordingly removed to facilitate the

refrigeratory process. It takes from eight to fourteen days for the liquor to cool and deposit its crystals; the mother liquor remaining in the centre is then run off through a hole bored in the side of the crystalline mass, which is then broken up into irregular square blocks and sent into the market.

By the use of a purer raw material than the alum shale above mentioned, the processes may be much simplified, so far at least as regards the production of the sulphate of alumina. Thus, in some manufactories, pipe-clay or china-clay containing little else than silicate of alumina, contaminated with only a small quantity of oxide of iron, is gently roasted in a reverberatory furnace, and then decomposed by hot sulphuric acid which combines with the alumina, expelling the silicic acid chiefly in the insoluble form. The mass thus obtained is now lixiviated with water, and there is thus obtained a concentrated solution of sulphate of alumina, which is subsequently converted either into potash or ammonia alum in the manner already described.

A large quantity of alum is now made by Spence's process, which is peculiarly fitted for coal districts, inasmuch as the whole of the materials employed are derived from coal and the coal strata. Thus the iron pyrites so frequently met with amongst coal in lenticular masses or distinct strata, furnishes sulphuric acid [SULPHURIC ACID] which, when heated in large shallow leaden pans with roasted coal shale (a material very similar in composition to alum shale), yields sulphate of alumina, containing an excess of sulphuric acid. A quantity of the ammoniacal liquor of gasworks [GAS] is now boiled in a close vessel, and the vapours of carbonate of ammonia and sulphide of ammonium arising therefrom are conducted into the hot acid solution of sulphate of alumina, where they are converted into sulphate of ammonia, which immediately forms ammonia alum with the sulphate of alumina present, whilst carbonic acid and sulphuretted hydrogen gases escape. On cooling, the solution deposits a copious crop of alum crystals, which are purified by washing and recrystallisation, in the manner already described.

Properties.—Alum presents the appearance of colourless, tolerably transparent octohedral crystals, which possess a sweetish astringent taste, and are soluble in about 18 parts of cold water and less than their own weight of boiling water. These crystals contain 24 equivalents of water, which they lose on exposure to a heat of about 400°, and are converted into a light, porous, white, insoluble mass termed *burnt alum*. At a bright red heat ammonia alum is totally decomposed; ammonia and sulphuric acid are volatilised, whilst pure and anhydrous alumina is left behind. For the chemical relations of alum, see ALUMS.

Uses.—Alum is largely employed in dyeing and calico-printing, and in the manufacture of paper; it is also used in the production of pigments called *lakes*, and is sometimes mixed with the flour used for bread. A minute quantity of alum thus employed renders the bread, especially if made from the inferior kinds of flour, lighter, whiter, and probably more digestible; it also enables the bread to retain a larger amount of water after baking. It is easy to perceive that these properties may, on the one hand, be made fraudulently subservient to the production of bread apparently of the best quality from inferior flour; and on the other, may be legitimately used as means whereby such flour, when it must be employed as food, may be converted into a more palateable and wholesome bread. The amount of alum (about $\frac{1}{1000}$ of the weight of the flour) required to produce this effect, is too minute to exercise any deleterious effect upon the consumer of such bread.

In all these applications it is immaterial whether potash alum or ammonia alum be employed; weight for weight, however, ammonia alum is rather more valuable than potash alum, since it contains 11·90 per cent. of the active ingredient, alumina, whilst potash alum contains only 10·82 per cent.

About 20,000 tons of alum are now annually manufactured in the United Kingdom.

ALUMINA (Al_2O_3). The oxide of aluminium; it constitutes a large proportion of all clays, which in a great measure owe to it their plastic property. The name of alumina is derived from *alumen*, the Latin for alum, the salt from which it is generally obtained in a pure state, by means which will presently be mentioned. Alumina is widely diffused in nature; the adamantine spar or corundum, the ruby, and sapphire, are alumina nearly pure and crystallised, and are among the hardest substances in nature. The diaspore is a crystallised mineral, which consists almosts entirely of alumina and water; and in North America another hydrate of alumina has been found, and called gibbsite. Emery, likewise remarkable for its hardness, and hence much used for grinding and polishing, is also alumina coloured with the oxides of iron and manganese.

The following is the process recommended by Berzelius ('Traité de Chimie,' ii. 369) for procuring pure alumina: Dissolve and crystallise alum repeatedly, to deprive it of the peroxide of iron which it usually contains; when thus rendered pure, a portion of the alum dissolved in water, and added to a solution of potash in excess, gives a precipitate at first, which is afterwards completely redissolved. To a boiling solution of the purified alum, add one of carbonate of potash, as long as precipitation takes place; then a slight excess of the carbonate being used, digest with a gentle heat to decompose the subsulphate of alumina formed. Wash this carefully on a filter, and redissolve it in hydrochloric acid; precipitate the clear solution with ammonia or carbonate of ammonia, and wash the precipitate, which, when dried with a gentle heat, is hydrate of alumina, and when heated to redness becomes pure alumina, by losing its water.

If intended for the purpose of solution in acids, it is better to keep the alumina in the state of hydrate; for when once rendered anhydrous, acids act upon it slowly and with great difficulty. Pure anhydrous alumina may also be obtained by heating ammonia alum to redness.

Hydrate of alumina, when recently precipitated, presents the appearance of a white, bulky, semi-transparent, gelatinous substance; on drying it contracts greatly and forms a white powder, which adheres to the tongue strongly. Hydrate of alumina readily combines with acids, except carbonic acid, forming salts which are generally soluble and uncrystallisable. They all possess an acid reaction. If the acid be volatile, a portion of it is generally expelled on boiling a solution of the salt, and a basic compound is precipitated. With acetate of alumina this takes place at ordinary temperatures; as, for instance, in the *ageing* of calico, which has been mordanted with acetate of alumina, acetic acid passes off during the ageing process, and a basic and insoluble acetate becomes fixed in the fibre, forming what is termed the *mordant*. Hydrate of alumina, as usually prepared, is insoluble in water; but Walter Crum has described a curious modification of it, which dissolves in large quantity in water containing a minute amount of acetic acid. Hydrate of alumina is readily soluble in solutions of the fixed alkalies, but insoluble in ammonia. If its solution in caustic potash or soda be exposed to the air, carbonic acid is gradually absorbed, and terhydrate of alumina (Al_2O_3, 3 HO) deposited in small but well-defined crystals.

When strongly heated, hydrate of alumina becomes suddenly incandescent, contracts greatly, and loses its water of hydration. It is then nearly insoluble in acids, but may be fused before the oxyhydrogen blowpipe, yielding an exceedingly hard vitreous mass, resembling corundum.

Alumina is an important substance, whether regarded as the ore of the metal aluminium, as a constituent of soils, or with respect to its extensive employment in the operations of the dyer, calico-printer, and colour-maker. It is also a necessary ingredient in all kinds of porcelain, earthenware, bricks, and tiles.

ALUMINA, SULPHATE OF. (Al_2O_3, $3SO_3 + 18aq.$) A salt formed by dissolving hydrate of alumina in dilute sulphuric acid, and then evaporating the solution. It crystallises in colourless flexible scales, containing eighteen atoms of water. They are soluble in twice their weight of cold water. Sulphate of alumina has an astringent and acid taste; it is permanent in the air, and is nearly insoluble in alcohol. It is used in dyeing and calico-printing, in the place of alum, for the production of mordants; and, as a general rule, it may be employed for all the purposes to which alum is applicable. For these applications sulphate of alumina is manufactured on a large scale by treating the white previously calcined clays of Devonshire and Dorsetshire with their own weight of dilute sulphuric acid, specific gravity 1·200 at the temperature of boiling water; and then, after separating the insoluble silica, precipitating the small amount of peroxide of iron, which is dissolved as sulphate, with ferrocyanide of potassium. The Prussian blue thus formed is allowed to subside, and the supernatant liquor is concentrated by evaporation, until it solidifies on cooling into a white mass, which is nearly pure sulphate of alumina, containing from 13 to 14 per cent. of alumina. The commercial salt thus manufactured is sometimes called *patent alum*.

A less pure, but almost equally efficacious, sulphate of alumina is made by a still more simple process, and is sold under the name of *aluminous cake* [ALUMINOUS CAKE].

ALUMINIUM, the metal contained in alumina. Aluminium was first obtained in a state approaching to purity by Wöhler, in 1827, by decomposing chloride of aluminium by means of potassium. Its preparation has since been simplified and rendered practicable on the large scale by Bunsen and by Deville. The former chemist prepares it by the electrolytic decomposition of the double chloride of aluminium and sodium ($Al_2Cl_3 + NaCl$). The melted salt is maintained at a temperature of about 400°; and as the metal separates at the negative pole, which consists of a plate of gas-carbon, it sinks to the bottom of the crucible containing the melted salt, and is thus protected from oxidation. On subsequently raising the temperature, the particles of aluminium coalesce into a large globule.

M. Deville, to whom we are indebted for a process capable of preparing the metal on a manufacturing scale, obtains aluminium by decomposing its chloride with sodium. The chloride of aluminium he prepares as follows:—anhydrous alumina is mixed with charcoal, made into a paste with oil or tar, and ignited in a covered crucible. When cold, the mass, which now consists of alumina and carbon, is broken into fragments and placed in an earthenware retort, with the short neck of which a glass receiver is connected. The retort and its contents being heated to dull redness, a current of dry chlorine gas is introduced through the tubulare, and solid chloride of aluminium immediately begins to condense in the receiver. The following is the reaction:—

$$\underbrace{Al_2O_3}_{\text{Alumina.}} + \underbrace{3C}_{\text{Carbon.}} + \underbrace{Cl_3}_{\text{Chlorine.}} = \underbrace{Al_2Cl_3}_{\text{Chloride of aluminium.}} + \underbrace{3CO.}_{\text{Carbonic oxide.}}$$

If, however, the chloride is to be at once employed for the preparation of the metal, it is better to conduct the vapour from the neck of the retort over ignited chloride of sodium, by which the double chloride of aluminium and sodium is produced. For the preparation of aluminium, 400 parts of this double salt are mixed with 200 parts of chloride of sodium and 200 parts of fluor spar (fluoride of calcium), all perfectly dry and in fine powder. This mixture is then placed in a crucible, interstratified with 75 to 80 parts of sodium; the whole being covered with a layer of powdered chloride of sodium. The crucible is heated at first gently, until the sodium begins to act, and afterwards to the melting point of the materials, which are to be stirred about with a porcelain rod and then poured out into a convenient mould. The cooled mass will contain a regulus of about 20 parts of aluminium, and a further quantity of about 5 parts in small globules. The reduction of chloride of aluminium by sodium may be thus expressed:—

$$\underbrace{Al_2Cl_3}_{\text{Chloride of aluminium.}} + \underbrace{3Na}_{\text{Sodium.}} = \underbrace{Al_2}_{\text{Aluminium.}} + \underbrace{3NaCl.}_{\text{Chloride of sodium.}}$$

Earthenware crucibles lined with a mixture of lime and alumina are used for the reduction.

Cryolyte, a native double fluoride of sodium and aluminium ($3NaF + Al_2F_3$), has been also used in a similar manner by Percy and Rose for the preparation of aluminium.

Aluminium thus prepared is a blueish-white metal, of a lustre inferior to silver. When cast, it is as soft as pure silver, and has a specific gravity of 2·56, about equal to the lightest descriptions of glass. By hammering and rolling, it becomes nearly as hard as iron, and has then a specific gravity of 2·67. Its melting point lies between those of zinc and silver. It is slightly magnetic, and conducts electricity eight times better than iron. Exposed to the air it does not oxidise, even at a red heat, and may be placed in contact with boiling water for any length of time without undergoing change. Dilute or concentrated nitric acid do not act upon it in the cold, and even concentrated boiling nitric acid dissolves it only with extreme slowness. On the other hand, dilute hydrochloric acid and solutions of fixed alkalies readily act upon and dissolve it, with the evolution of hydrogen. It is not tarnished like silver by sulphuretted hydrogen, and does not amalgamate with mercury by simple contact. It can be wrought with about the same ease as silver, and has already been used to a considerable extent by the silversmith and jeweller. In beauty of surface it is inferior to silver, but its extraordinary lightness and permanency in the air will probably lead to its employment for articles in which these qualities are a desideratum.

ALUMINIUM, CHLORIDE OF. [ALUMINIUM.]

ALUMINOUS CAKE, an impure sulphate of alumina, recently patented by Mr. Pochin, and which is now employed to a considerable extent as a substitute for alum in the preparation of mordants and in the manufacture of paper. It is prepared by gently calcining china clay, selected as free from iron as possible, and then when cold mixing it with concentrated sulphuric acid in a leaden vat. A coil of leaden pipe is placed at the bottom of the vat, and steam passed through the former until the sulphuric acid begins to act upon the clay. The hot mixture is then run into a shallow flag vat with moveable sides; here the action becomes every moment more violent, torrents of steam are evolved from innumerable little craters, and finally, the mixture solidifies to a hard, honey-combed, grayish-white mass, which consists almost entirely of silica and sulphate of alumina. When this mass is treated with water, the sulphate of alumina dissolves, whilst the silica remains behind in an insoluble condition. The following analysis shows the composition of aluminous cake:—

Alumina (as soluble sulphate)	13·44
Peroxide of iron (as soluble sulphate)	·26
Insoluble basic sulphate of alumina	2·99
Soluble silicic acid	·01
Insoluble silicic acid	18·70
Insoluble alumina (as silicate)	3·38
Sulphuric acid (in soluble sulphates)	32·81
Sulphates of soda and potash	·87
Lime	·50
Magnesia	trace
Water	27·04
	100·00

As the sulphate of alumina is the only ingredient in alum which is made use of in nearly all the processes to which the latter salt is applied, it follows that aluminous cake may be effectively substituted for alum, whilst, being considerably cheaper and containing a larger proportion of alumina, its use is more economical.

ALUMS. A name applied by chemists to an important class of salts, to which commercial ammonia alum and potash alum belong. The alums are essentially double salts, consisting of an alkaline sulphate combined with the sulphate of a sesquioxide base, and crystallising generally in octohedrons with twenty-four atoms of water.

The following are the principal salts belonging to this class:—

Potash alum	$KO, SO_3 + Al_2O_3, 3SO_3 + 24$ aq.
Ammonia alum	$(NH_4)O, SO_3 + Al_2O_3, 3SO_3 + 24$ aq.
Soda alum	$NaO, SO_3 + Al_2O_3, 3SO_3 + 24$ aq.
Iron alum	$KO, SO_3 + Fe_2O_3, 3SO_3 + 24$ aq.
Manganese alum	$KO, SO_3 + Mn_2O_3, 3SO_3 + 24$ aq.
Chrome alum	$KO, SO_3 + Cr_2O_3, 3SO_3 + 24$ aq.

AMALEKITES, a nation who dwelt S.W. of Palestine, between Edom and Egypt. (Gen. xiv. 7; Exod. xvii. 8—16; 1 Sam. xv. 7.) According to Josephus ('Antiquities,' iii. 2), those who dwelt in Gobolitis and Petra were called Amalekites, and were the most warlike among the surrounding nations. He calls their country Amalekitis, and describes it as a part of Idumæa. ('Antiq.' ii. 1.) Josephus also calls the country of Midian Amalekitis, and says that it was situated between Pelusium, on the borders of Egypt, and the Red Sea. ('Antiq.' vi. 7; s. 3, and ch. 8.) It appears also that they occupied several places in Palestine among the Canaanites, and in the land of Ephraim we find a mountain of the Amalekites where Abdon, the son of Hillel, was buried in Pirathon.

The Amalekites were the first who opposed the Israelites on their march from Egypt. (Exod. xvii. 8—13; Jos. 'Antiq.' iii. 2.) They suffered great loss, but were afterwards assisted by the Canaanites, and obtained a great victory. (Num. xiv. 39—45.) During the time of the Judges, the Israelites were frequently oppressed by the Amalekites, Ammonites, and Midianites. (Judges iii. 13; vi. 3; Joseph. v. 7.) Saul fought with the Amalekites, and took their king Agag alive, who was cut to pieces by the prophet Samuel. (1 Sam. xv.; Jos. 'Antiq.' vi. 8.) David warred against them (1 Sam. xxvii. 8); and therefore the Amalekites plundered the town of Ziklag, and set it on fire, but David overtook them in the wilderness and recovered all that they had carried away. (1 Sam. xxx. 18; 'Antiq.' vi. 15.) The Amalekites were finally extirpated by the Simeonites, who occupied their country during the reign of Hezekiah (1 Chron. iv. 43), and this is the last notice of them. Thus, according to the direction of Moses, the remembrance of Amalek was blotted out from under heaven, because they slew the hindmost of the Israelites who fainted in the wilderness. (Deut. xxv. 17, 19.) Josephus says that Haman, called in the book of Esther an Agazite, was an Amalekite. Le Clerc, Hengstenberg, and others, assert that there was more than one tribe of Amalekites, an opinion founded chiefly on the difference of their localities: but the Bible narrative makes no distinction, and their national character, that of a warlike and pastoral race, will account for their dispersion.

AMALGAM, a compound of two or more metals, of which one is always mercury; and this circumstance distinguishes an *amalgam* from a mere *alloy*. Nature presents us with only one amalgam, which is of silver, and is termed by mineralogists *native amalgam*: it occurs in Hungary, Sweden, &c., and is met with either semi-fluid, massive, or crystallised in rhombic dodecahedrons. Klaproth found it to consist of 64 parts of mercury and 36 of silver in 100 parts. Most metals may be amalgamated with mercury, and the combination appears to depend on chemical affinity. When the cohesion of a metal is slight, as in the cases of potassium and sodium, or when its affinity for mercury is considerable, as in the instances of gold and silver, amalgamation takes place readily by mere contact. When, on the other hand, the cohesion of a metal is strong, or its affinity for mercury is weak, heat, or intermediate action, or both, are requisite to effect amalgamation.

There are several circumstances which show that amalgamation is the result of chemical affinity; the crystalline form of the native amalgam is strongly indicative of it, and it is confirmed by analysis; for if the quantities of mercury and silver were 64 of the former and 34·56 of the latter metal, instead of 36, as above mentioned, they would be in the proportions of 200 to 108, or 1 atom of each.

The phenomena also which accompany the action of mercury upon other metals evince its chemical nature: if 44 parts of mercury be mixed with 1 part of potassium, combination occurs with the evolution of much heat, and when the resulting amalgam is cold, it is hard, and has the appearance of silver. When the quantity of mercury exceeds 100 parts to 1 part of potassium, the compound is liquid; and an amalgam containing only 1·5 per cent. of potassium is susceptible of crystallising. The density of an amalgam exceeds that of the mean of the metals.

There are some metals, it has been already observed, which require heat in order to amalgamate them; of these antimony offers an example. In order to effect combination it must be melted, and while liquid mixed with hot mercury. Mere heat, however, causes no action between iron and mercury. It has been stated, however, that they may be amalgamated by mixing the filings of the metal with powdered alum, and rubbing them together in a mortar with a little water: after trituration the alum may be washed out; but an amalgam of iron may best be formed by rubbing the latter metal with an amalgam of sodium. By the intervention of tin or zinc, iron may be combined with mercurcy, and a double amalgam is formed. Platinum also unites with mercury by the intervention of the amalgam of potassium or sodium, but not by direct action. Many metals otherwise difficult to amalgamate, such as iron, platinum, and aluminium, may be combined with mercury when placed in contact with the latter metal in acidulated water, and made the negative pole of a voltaic circuit. The nascent hydrogen is here supposed to induce the amalgamation.

Having stated some examples of the different modes in which amalgams may be formed, we shall notice their general properties. Amalgams are either liquid, soft, or hard; their form being dependent, in some cases, upon the quantity of mercury employed; and, in others, upon the nature of the metal amalgamated: thus an amalgam consisting of 80 parts of mercury and 1 part of sodium is solid, whilst a compound of 15 parts of mercury and 1 part of tin is liquid. The liquid amalgams resemble mercury in appearance, except that the greater part of them flow less readily. Solid amalgams are brittle. In general, amalgams are white; they are all crystallisable, and then form compounds in definite proportions. To prove this, it is only requisite to dissolve a proper quantity of a metal in mercury with heat, and to allow the amalgam to cool; it then separates into two portions, one of which is liquid, and the other is solid and crystallised; the fluid portion may, however, be regarded as a solution of the definite compound in the excess of mercury. The amalgams of the more oxidable metals, as of potassium and sodium, are decomposed by exposure to the air and absorption of oxygen, and they decompose water with the evolution of hydrogen gas. The double amalgam of iron and zinc does not rapidly undergo any change. All amalgams are decomposed by a red heat, the mercury being volatilised, and the more fixed metals remaining. The processes of amalgamation and decomposition are employed to separate gold and silver from their ores; the mercury obtained by distilling the amalgams is repeatedly used for the same purpose, with comparatively little loss. The amalgams of gold and silver are employed in the processes of gilding and plating. The amalgam of tin is largely used in what is termed silvering mirrors, and various amalgams of tin and zinc are employed for exciting electricity in the machine. These compounds, as well as other amalgams, will be treated of under each particular metal. Some curious effects result from the action of amalgams upon each other: if mercury be added to the liquid amalgam of potassium and sodium, an instant solidification ensues, and heat enough to inflame the latter metals is evolved. When, on the other hand, a solid amalgam of bismuth is put in contact with one of lead, they become fluid, and the thermometer sinks during their action. There is a curious compound called an amalgam of ammonium, the real nature of which has not been satisfactorily explained. When mercury is made the negative pole in a solution of ammonia; or an amalgam of mercury and potassium is placed in solution of chloride of ammonium, the metal increases in volume twenty fold, and becomes of the consistence of butter; this phenomenon appears to be owing to the combination of *ammonium* with mercury. When thrown into water it effervesces copiously, hydrogen gas is given off, and ammonia remains in solution. Ammonium amalgam, when left to itself, spontaneously decomposes into liquid mercury and a mixture of two volumes of ammoniacal gas with one volume of hydrogen.

AMALGAMATION. The process of combining any metal with mercury. Technically it is applied to the metallurgic process by which gold and silver are separated from their ores. [AMALGAM; GOLD; SILVER.]

AMALGAMATOR. Shortly after the discovery of gold in Australia, many varieties of machines were invented for crushing the quartz ore, amalgamating the powder with mercury, and separating the pure gold by this means. The machines were in some instances called 'Crushers,' some 'Amalgamators,' and some 'Separators;' such as 'Tyzard's Quartz Crusher and Separator,' 'Wright's Quartz Crusher and Amalgamator,' 'Baggs's Gold and Silver Ore Amalgamator and Separator,' &c. All that need be described on this subject will be found under AMALGAM; GOLD.

AMALIC ACID ($C_{12}H_7N_2O_8$). One of the products obtained from the action of chlorine upon caffeine. When a current of chlorine is transmitted through a thick magma of crystals of caffeine suspended in water until nearly the whole of the alkaloid is decomposed, the liquid yields on evaporation colourless granular crystals of amalic acid, which stain the skin pink and assume a violet colour when moistened with baryta water. When exposed to the vapour of ammonia amalic acid forms a magnificent purple-colored body, homologous with murexid, and termed caffeomurexid ($C_{36}H_{24}N_{10}O_{16}$).

These reactions attach amalic acid to the uric series, and, in fact, it may be regarded as dimethyl-alloxantin, that is, alloxantin in which two atoms of hydrogen are replaced by methyl ($C_8(C_2H_3)_2N_2O_7$). [URIC SERIES.]

AMANDINE. The vegetable casein found in sweet and bitter almonds.

AMARINE ($C_{42}H_{18}N_2$). An organic base produced by the action of ammonia upon the essential oil of bitter almonds (hydride of benzöyl). An alcoholic solution of oil of bitter almonds is saturated with ammoniacal gas and then allowed to stand for one or two days, at the end of which time it solidifies to a crystalline mass. This is boiled with water until most of the alcohol has been driven off, and whilst the liquor is still hot it is saturated with hydrochloric acid. An oily matter, sometimes mixed with crystals of *benzimic acid*, now separates, and the clear liquid, which must be decanted from the oil whilst still hot, contains the hydrochlorate of amarine in solution; on the addition of ammonia, crystals of amarine gradually precipitate and may be purified by recrystallisation from alcohol.

Amarine may also be obtained by the action of potash upon hydrobenzamide, and by the distillation of a mixture of hydrate of lime and sulphite of benzöyl-ammonia.

Amarine crystallises in needles, possessing a very slightly bitter taste. It is insoluble in water, but tolerably soluble in boiling alcohol, and also in ether. It possesses a slight but decided alkaline reaction, is fusible by heat, and volatilises at a higher temperature, undergoing at the same time decomposition. A boiling solution of bichromate of potash in dilute sulphuric acid, rapidly oxidises it, producing a large quantity of benzoic acid. Submitted to destructive distillation it yields, amongst other products, an organic base—*lophine* ($C_{42}H_{17}N_2$).

The salts of amarine possess an intensely bitter taste, and, with the exception of the acetate, are very sparingly soluble in water.

AMARYTHRIN. A bitter semifluid body of uncertain composition, produced by exposing to the air for a few days a hot aqueous solution of orsellic ether.

AMASATINE. [INDIGO.]

AMAURO'SIS, from ἀμαυρόω (to darken or to make obscure), dimness of sight, blindness. [GUTTA SERENA.]

AMAZONS, a fabulous nation of female warriors. Wild and almost impossible as the stories relating to them for the most part are, the historians and geographers of antiquity bear testimony to the general belief that such a nation existed. All appear to agree in assigning them a Scythian origin. Two Scythian princes, according to Justin, wandering from their own country, reached the river Thermodon in Cappadocia with their followers, and settled there. The new comers in time provoked the anger of their neighbours, and, in a war which ensued, their male population was almost exterminated. The women then took up arms, and with so much better success, that in future they resolved to live without men, and put the remaining males to death. They elected two queens, who in turn commanded their armies in the field, and kept order at home. They are said to have extended their conquests far and near, and to have founded many cities in Asia Minor, as Ephesus, Smyrna, Cumæ, and others; and indeed they are placed by different authors in so many different parts of Asia Minor, that nothing certain can be made out respecting them. Their chief seat, however, was Themiscyra, on the river Thermodon, near the southern coast of the Euxine Sea. Diodorus places a tribe of Amazons in Lybia; far more ancient, he says, than those settled on the Thermodon. The Amazons are said to have been warred on by Heracles (Hercules) and by Dionysus (Bacchus); to have invaded Attica in the time of Theseus, under the command of Hippolyta; and the battle between the Amazons and Athenians was painted at Athens in the celebrated portico called Poikile (the painted). The Amazons came to the assistance of the Trojans against the Greeks under the command of Penthesilea, who was slain by Achilles. (Virgil, 'Æn.' i. 494.) They did not neglect the care of continuing their race, but only brought up female children, whom they educated in all the arts of war, searing the right breast, that it might not interfere with the free use of the arm. They are usually figured, in medallic and other representations, with a short mantle reaching to the knee, the left breast bare. By the orator Lysias they are said to have been the first who fought on horseback, and to have had iron weapons which were not in use among their neighbours. This may, perhaps, have arisen from the geographical position assigned to them, near the country of the Chalybes, or workers in iron. Their weapons were a semicircular or crescent-shaped shield, bows and arrows, and the double-edged battle-axe, which was their peculiar and distinguishing weapon. Even in times of ascertained and credible history, we still find rumours concerning these singular beings; for it is asserted by Diodorus and Curtius, although the story is exploded by Arrian, that Thalestris, Queen of the Amazons, paid a visit to Alexander in Hyrcania; and by Plutarch, that certain Amazons fought with the Albanians against Pompeius. Of their name various derivations are given: for example, that they are so called from ἅμα ζώσας, 'females living together;' or from ἄνευ μάζου, 'without a breast.' A more recent opinion is that the name is derived from the Tscherkessischen, *maza*, the moon, and applies to a people in Upper Asia, whose chief deity was that planet. The notion of such a race has been ascribed to embellished rumours of the modes of life peculiar to the women of some Caucasian districts, and of remarkable instances of female bravery, which, in the same regions, are not unknown even in modern times.

The story of a race of Amazons is not confined to Asia. Alvarez, who visited Abyssinia in 1520, speaks of a race of Amazons south of Damot, who were warlike, and fought with bows and arrows, mounted on bullocks. They destroyed the left breast when young. They lived with their husbands, but were governed only by a queen: the men had nothing to do with war. Orellana, also, on his descent of the river Amazonas, in 1542, met with a tale of a nation of women, which of course vanished on investigation; though the fiction gave its name to one of the mightiest rivers of the newly-discovered continent, and which it has ever since retained. (Pierre Petit, 'Traité Historique sur les Amazons;' Herod. iv. 110-116; Strabo; Diodorus; Justin.)

In Greek art the Amazons were very frequently represented; and usually with an Asiatic character in contour and costume. Statues of Amazons in marble and bronze, and representations of them on sarcophagi, vases, gems, coins, &c., are extant in most public and many private collections. The combats of the Greeks and Amazons are represented on two very important series of bassi-rilievi in the British

Museum: 1. On twelve slabs from the temple of Apollo Epicurius (the Deliverer) on Mount Cotylion, near Phigalia, in Arcadia; and 2. On several slabs forming part of the frieze of the famous tomb erected at Halicarnassus, in honour of King Mausolus, by his wife Artemisia. Figures of the Amazons occur as wall paintings at Pompeii.

(Rasche, *Lexic. Rei Num.*; Müller, *Handb. der Archäol.* §§ 365, 412, 417, &c.)

AMBASSADOR is the term most commonly used by writers on public law to designate every kind of diplomatic minister or agent, and may, in this sense, be defined to be a person sent by one sovereign power to another to treat upon affairs of state.

Among the ordinary functions of an ambassador, the following are the most important: First, to conduct negociations on behalf of his country. The extent of his authority in this respect is limited by the power which he has received; he has, however, by the modern law of nations, no authority to conclude any engagement definitively, the treaty which he has negociated having no binding power till it has been formally ratified by his government. Secondly, to watch over the accomplishment of all existing engagements; and, Thirdly, to take care generally that nothing is done within the territories of the state, nor any treaty entered into with other powers, by which the honour or interests of his country can be affected, without informing his government of such measures.

Besides these more public functions, an ambassador has certain duties to perform towards private individuals of his own nation: such as to provide them with passports; to present them at court, if they produce the requisite testimonials; to protect them from violence and injustice; if any manifest wrong has been done, or if justice has been refused them, to obtain redress, and to secure for them the full benefit of the laws; and, lastly, to assist them in maintaining their rights in courts of justice, as well by certifying what is the law of his country upon the point in dispute, as by the authentication of private documents, which is usually confined in practice to such as have been previously authenticated at the foreign-office of his own government, and thence transmitted to him.

The right which exists in every sovereign power, of communicating by means of ambassadors, implies on the part of the state to which such communications are made, certain corresponding duties. (Grotius, ii. c. 18.)

The first of these duties is that of receiving the ambassadors sent to it. This is a duty, however, which exists only between nations at peace with each other; for, in time of war, a hostile power cannot claim to have its ambassadors received, unless they are provided with a safe-conduct or passport; and the granting of these is merely a matter of discretion. And in order to claim the performance of this duty, it is, in all cases, requisite that the ambassador should be provided with the proofs of his authority; these are contained in an instrument called his Letters of Credence, or Credentials, delivered to him by his own government, and addressed to that of the state to which he is sent. [CREDENTIALS.] A refusal to receive an ambassador properly accredited, if made without sufficient cause, is considered a gross insult to the power that he represents. But if one of several competitors for the sovereign power in any country, or if a province which has revolted and asserts its independence, claims to send an ambassador, a government, so far from being bound to receive the person so sent, cannot do so without thereby taking upon itself the responsibility of recognising the competitor in the one case to be actually the sovereign, and the revolted province in the other to be actually independent. Though this may be the general principle, the practice is somewat different. In such cases, consuls are generally first sent; and when a *de facto* power has been established for some time, governments think themselves justified in following up these consuls by ministers, even though the mother country, to which the revolted states belong, may not have recognised their independence. This was done by the British government and others in the case of the South American States.

The next great duty of a state, with respect to ambassadors sent to it, is to protect them from everything which may in any degree interfere with the due performance of their functions. This duty commences even before the ambassador has delivered his credentials, as soon as his appointment has been notified to the court. This is the principle on which are founded what may be called the essential privileges of an ambassador.

The first of these privileges is that of perfect security; for as he is necessarily placed among those who have always the power, and, from the nature of his duties, not unfrequently the will to molest him, it is requisite that he should be in the fullest manner protected from every kind of violence whatever, either to his person or his property. The breach of this privilege has, from the earliest ages been considered a high offence against the rights of nations, whether proceeding from the sovereign power itself, or from the unauthorised acts of individuals.

The second essential privilege of an ambassador is, that no legal process can affect him, in his person or his property; at least so much of his property as is connected with his official character, such as his furniture, equipages, &c. Ambassadors are therefore deemed not to be amenable for their conduct before any *civil* tribunal of the country they reside in.

No claim can be enforced against an ambassador by any compulsory process whatever. It is a matter of dispute how far an ambassador is privileged in matters in their nature *criminal*. (Blackst. 'Comm.' Mr. Kerr's ed. vol. i. p. 247.)

These privileges are not confined to the ambassador alone, but are extended to all his suite—his companions as they are sometimes called,—including not only the persons employed by him in diplomatic services, but his wife, chaplain, household, &c. The law of nations in this respect is fully recognised by the law of England. By the statute of 7 Ann. c. 12, all legal process against the person or goods of an ambassador, or of his domestic, or domestic servants, is declared to be void. (Blackst. 'Comm.' *supra.*)

The third essential privilege of an ambassador is, that his residence enjoys a security similar to that of his person and property: it is not only protected from open outrage, but is likewise exempted from being searched or visited, whether by the police, by revenue officers, or under colour of legal process of any description whatever.

The salaries and pensions for diplomatic services are paid out of the consolidated fund, and are regulated by 2 & 3 Wm. IV. c. 116.

For further information on the subject of ambassadors, the reader may consult Wicquetort, 'De l'Ambassadeur;' 'Les Causes Célèbres du Droit des Gens,' by C. De Martens; and the writers on the law of nations, particularly Vattel and G. F. Martens; and likewise the 'Cours de Droit Public,' par Pinheiro-Ferreira.

The functions of permanent ambassadors appear to have originated in modern times. The ambassadors (πρέσβεις) sent by the Greek states, and those sent by the Romans (legáti) or received by them, were limited to extraordinary occasions. Among the Romans, ambassadors were often sent by foreign nations to them, and sent by the Romans to foreign states, and the law with respect to them (Jus Legationis; Livy, vi. 17)b ecame in course of time well settled. Ambassadors to Rome were under the protection of the state, whether they came from a hostile or a friendly nation. They were received by the Roman senate and transacted their business with that body. The senate appointed the ambassadors who were sent from Rome to foreign states. The expenses of such ambassadors were paid by the Roman state, but the ambassadors were also entitled to make certain demands from the provincials in their progress through a Roman province.

The word 'legatus' is a participle from the verb 'lego,' and signifies a person who is commissioned or empowered to do certain things.

AMBER. A resinoid body, either exuded from certain plants of the coal epoch or produced during the formation of coal and lignite. It is found most abundantly on the shores of the Baltic, where it is often washed upon the beach during the autumnal storms. It has also, though rarely, been found on the Scandinavian coast, in Greenland, England, Italy, Spain, Sicily, Siberia, China, and the United States. Its colour varies from light yellow to brownish yellow, orange-red, and brownish black. It is generally translucent, but sometimes milk-white and opaque, has a resinous conchoidal fracture, and bears a good polish, hence its employment in jewellery. When rubbed it becomes strongly electric. Heated to 550° it fuses, gives off an agreeable aromatic odour, and burns with a clear flame. Its specific gravity is 1·065 to 1·070. It is inodorous and tasteless, entirely insoluble in water, but soluble in spirit of turpentine by the aid of heat.

Amber contains a volatile oil (oil of amber), succinic acid, and two resins soluble in alcohol and ether; its chief constituent, however, is a peculiar substance—*amber bitumen*, insoluble in alcohol and ether. Amber, when freed from everything soluble in ether, has the same composition as laurel camphor, which may be expressed by the formula $C_{20}H_{16}O_2$.

AMBERGRISE. An organic substance of uncertain origin, said to be a diseased secretion of the Spermaceti Whale, and to be found floating on the sea near the coasts of Madagascar, Coromandel, Japan, and the Moluccas; it is of a greyish colour with darker streaks running through it. In the hand it softens like wax, and exhales an agreeable odour. Its specific gravity is about 0·91. It contains a volatile oil, and benzoic acid, but its chief constituent is Ambrein, of which it contains about 85 per cent.

AMBREIC ACID. [AMBREIN.]

AMBREIN ($C_{33}H_{32}O$). A fatty body analogous to cholesterin found in ambergris. From boiling alcohol it crystallises in fine colourless needles, tasteless, but possessing an agreeable odour. Ambrein fuses between 86° and 104°, or may be distilled without alteration. It is very soluble in ether, and in fixed and volatile oils, but is not saponifiable. Nitric acid converts it into ambreic acid.

AMBROSIAN LIBRARY at Milan. The Ambrosian Library owes its existence to the munificence of Cardinal Frederick Borromeo, archbishop of Milan. He laid the foundation of it in 1602, and it was opened to the public in 1609. Its name was given in memory of St. Ambrose, archbishop and patron-saint of Milan. Frederick Borromeo not only placed his own collection of books in this library, but sent his librarian, Anthony Oggiati, into different countries to purchase additions. Montfauçon assures us that numerous manuscripts were obtained for it from Thessaly, Chios, Corcyra, and Magna Græcia: the founder added to these some very valuable accessions from the monastery of Bobbio (anciently Bobium), in the northernmost Apennines, together with a considerable assemblage of manuscripts from the Pinelli collection; the latter cost no less than three thousand four hundred ducats. It was the founder's original intention to join to the endowment of his library a college of sixteen learned men; but the want of funds reduced the number to four: of these, one translated Greek, a second taught Hebrew, a third Arabic, and a fourth was to make collections of whatever was valuable in authors. The Ambrosian Library now contains above sixty thousand printed volumes, with rather more than fifteen thousand manuscripts; and annexed to it is a gallery of pictures, statues, antiques of various kinds, and medals, and containing numerous articles of rarity and reputation. Many of its curiosities of every description were carried to France during Bonaparte's campaign in Italy, and with them a manuscript collection of the works of Leonardo da Vinci, accompanied with drawings and designs, which a citizen of Milan, of the name of Galeas Arconati, refusing every lucrative offer from private persons, had given to the Ambrosian Library. One volume of this collection was returned to the library after the Peace of Paris in 1814, but the remaining volumes, having been sent to the library of the Institute and not to the Bibliothèque du Roi, it was not at the time of the reclamation known where they were, and they are yet retained in Paris. Another rarity belonging to the Ambrosian collection is a manuscript of Virgil, the margins of which are interspersed with notes in the hand-writing of Petrarch: the 'Palimpsesti,' or rescript manuscripts, edited between 1814 and 1816 by Angelo Mai, were discovered in the Bobian portion of the Ambrosian collection. Oggiati, Muratori, and Mai, have been the three most eminent librarians of this library. Mai became afterwards the librarian of the Vatican. The hall is well proportioned, though not so large as might be expected for a collection of books and manuscripts so considerable. The ceiling is adorned with paintings, and the space between the book-cases and the cornice filled up by the portraits of the most eminent authors whose writings are deposited below.

(For further information on the Ambrosian Library we refer to Boscha *De Origine et Statu Bibliothecæ Ambrosianæ Hemidecas*, 4to. Milan, 1672; Saxius *De Studiis Literariis Mediolanensium Prodromus*, 8vo. Milan, 1729, p. 147; and Montfaucon's *Diarium Italicum*.)

AMBRY, or ALMERY, in Gothic churches a locker or closet used for keeping the sacramental elements, the ecclesiastical plate, vestments, documents, &c. Ambrys were usually formed in the thickness of the wall, enclosed with a door, and secured with a lock. In every church there was an ambry by the altar to contain the utensils belonging to it; but in large churches and cathedrals there were usually several in various parts of the building, and some of them of large size. Generally they were made to contribute to the architectural effect of the edifice by means of a traceried arch or a crocketed canopy: the doors were also sometimes considerably enriched. Few in this country at least retain their original fittings. In some of the French churches excellent examples of the mediæval ambry still remain.

AMBULANCE, a French word derived from the Latin *ambulare*, to walk or march, applied to the moving hospitals which are attached to and accompany every army, or division of an army, in the field; also to the means of transport for sick and wounded soldiers. As medical science increased, the necessity was felt for some organization of this kind to render immediate surgical and medical aid to sick and wounded soldiers. But the credit of the first introduction and organisation of an ambulance train on the present footing is due to the celebrated French surgeon Baron Percy, who, when head of the medical staff of Napoleon's army in Spain, formed the first battalion of the Ambulance Corps, having previously, when under Moreau, organised a *Corps Mobile de Chirurgie Militaire*. Since his time great improvements have been introduced, especially by the well-known Larrey, in this most important department, and have been adopted in the various armies of Europe. The ambulance trains usually consist of covered spring-waggons, with litters inside for the sick and wounded men, containing also surgical apparatus and medical comforts, though, of course, the patterns of these vary much in the different armies.

One of these, which may be more particularly mentioned as employed in the French army, and from it adopted in the English army during the Crimean war, consists of two stretchers hung one on each side of the pack-saddle of a mule or pony. The stretchers, made with an iron framework and canvass bottom, are so contrived as to fold up and make an arm-chair, or, being extended, to form a sloping bed.

These can accompany troops over more difficult ground than the waggons, and afford assistance to exhausted men who would otherwise be neglected and left on the line of march; or attending close to the scene of action, receive the wounded men who are carried to the rear on stretchers, and remove them with the utmost promptitude to the ambulance hospitals, which are placed out of reach of the enemy's fire.

(*Biographie Universelle*, Suppl. 76; also Larrey, *Mem. de Ch. Milit.* vol. i.)

AMBULATORY (from the Latin *ambulo*, to walk) is, in a substantive sense, a place to walk in. With reference to buildings, this term may be applied to the space enclosed by a colonnade or an arcade. In the peripteral temple of the Greeks, the lateral or flanking porticos are properly termed ambulatories; the cloister of a monastery is surrounded by an ambulatory or ambulatories. Of the external colonnaded ambulatory, the porticos of the *Bourse* or Exchange at Paris afford a good modern exemplification; and of an internal arcaded ambulatory, a good instance is afforded by the Royal Exchange in London. The aisles of the ancient Basilica, and those of its representative in later architectural works, the cathedral, or other large church, are sometimes called ambulatories.

In an adjective sense, ambulatory may be applied to anything, the functions of which require it to move from place to place. Formerly the Parliament and the Court of King's Bench in this country were termed ambulatory courts, because they were held sometimes in one place, and sometimes in another: indeed, wherever the king happened to be.

AMBUSCADE. A military term derived from the Italian *imboscare*, *imboscata*, to lie in bushes or concealed, *in* and *bosco*, *bosque*, a wood; Eng. *bush*. It is the same as the original English word ambush. It signifies the lying in wait, or concealed, to attack an enemy unprepared, and therefore at a disadvantage. In ancient times before the introduction of fire-arms, when armies were not encumbered with long trains of material, &c., this mode of attack was more common and more frequently successful than at present, when it can only be adopted with small and detached parties. And in fact we only hear of such things in wars against barbarous or semi-civilised peoples, or in a war of outposts. A case occurred in the late Indian mutinies where the party sent to relieve the fortified post of Arrah, then besieged by the mutinous Sepoys, while marching through a wood after nightfall, fell into an ambuscade, were surrounded, and nearly cut to pieces.

We do not include in this word an attack which, though unexpected and sudden, is made while the other party is aware of an enemy somewhere in the neighbourhood; or an unexpected attack made upon an enemy in position, which is called a surprise.

AMEN, a Hebrew word, properly signifying 'firmness,' and hence 'truth,' which has been adopted without alteration in various languages.

Its most frequent use is at the conclusion of prayers, thanksgivings, and denunciations, where it is understood to express belief, assent, and concurrence in what has been expressed. Examples of its use in all these cases are numerous in the Bible. When the priest has declared to the woman suspected of adultery the effect of the water of jealousy, "the woman shall answer, Amen, amen."—Numb. v. 22. When curses are pronounced against the wicked in Deut. xxvii. 15, all the people are ordered to repeat amen.

The word amen concludes all the gospels, and almost all the epistles; it is repeated at the end of four of the five sections of the Psalms according to the division of the Jews; namely, the 41st, the 72nd, the 89th, and the 106th Psalms; in this last Psalm it is followed by hallelujah, which word concludes the last section.

In many churches in England, the word amen is pronounced aloud by the people: this was the ancient practice of the Christian world, and St. Jerome relates, that when the congregated people at Rome pronounced amen, the sound was like that of a clap of thunder. They possibly attributed great efficacy to the loudness of their voices, after the example of the Jews, who imagined that this word, shouted forth with great force, had power to open the gates of heaven.

Amen is often used by our Saviour at the beginning of a discourse, as an impressive particle, which in our version is rendered 'verily.' In the Gospel of St. John the word is always repeated.

In one instance this word is used as an adjective, meaning certain, fixed. "For all the promises of God in him are yea, and in him Amen," 2 Cor. i. 20. In one other instance the word denotes our Saviour. "These things saith the Amen," Rev. iii. 14.

AMENDE HONORABLE. Amende in French is a penalty, so called from being regarded as a compensation for, or rectification and amendment of, the offence. According to the old laws of France, persons guilty of crimes coming under the head of public scandals, such as sedition, sacrilege, fraudulent bankruptcy, &c., used sometimes to be condemned to make a public confession of their guilt. This was called making the *amende honorable*, which was either simple, or *in figuris*, in which last case the culprit was conducted by the public executioner into open court in his shirt, with a rope about his neck, and a lighted torch in his hand, and in that state made his confession on his knees. The amende honorable was accounted an infamous punishment, and appears to have been so called as consisting altogether in the disgrace, and not in any fine or other actual suffering. The courts, however, were also sometimes wont to order a person by whom the reputation or honour of another had been injured to make a public acknowledgment of the wrong; and such a sentence carried no infamy with it. It is from this latter custom that the modern and popular use of the expression has been borrowed, according to which we say that a person makes the amende honorable when he publicly admits any wrong which he feels that he has done to another person.

AMENDMENT, in Law, signifies the correction of mistakes in the records of judicial proceedings. In the early period of our English law, the pleadings between the parties were conducted *ore tenus*, as it was called, at the bar of the court by their respective advocates. If any mistake occurred in the pleading of either party, it was corrected at once upon a suggestion made to the court. Subsequently, when oral pleading became superseded by the present practice of delivering written pleadings between the parties, the same indulgence as to amendments continued. Hence the courts upon application by either party, will amend the interlocutory proceedings in a cause; and at the present day will amend mistakes in the pleadings, whilst they continue in paper, upon proper terms. But anciently, after the proceedings were once entered on record, the judges considered that they had no authority to alter them in any respect; either for the purpose of correcting false Latin, of supplying a word, syllable, or letter accidentally omitted, or of removing any other clerical error. The consequence was, that after a suit had been decided in favour of one party, it frequently happened that his adversary discovered some blunder made by the officer of the court on making up the record and by bringing a writ of error, deprived the successful party of all the benefit of the judgment he had obtained. This inconvenient rule arose out of a rigid observance of an ordinance of Edward I., which directs the judges to record the pleas pleaded before them, but forbids them "to make their records a warrant for their own misdoings, or to erase or *amend* them, or to record anything against their previous enrolments." These words obviously imply nothing more than a reasonable restriction upon the alteration of the records of the court clandestinely or for sinister purposes, and certainly do not justify the strict interpretation afterwards applied to them. To the rule thus established there were several exceptions:—1. All errors in records might be amended during the same term in which they were made, because in contemplation of law the record is in the breast of the judges during the term, and not on the roll. 2. In an essoign, or excuse by a defendant for not appearing in proper time, if the plaintiff's name were mistaken, the mistake might be amended, because it was inconsistent with the writ, and, if enrolled in its erroneous form, it would be a record against a previous enrolment, and for that reason a breach of the ordinance. 3. For the same reason, a continuance, which is an entry on the record showing the continuation of a cause from one term to another, might be amended so as to make it correspond to the proceedings previously recorded.

It is plain that these ingenious exceptions would afford little relief from the strictness of the rule; and in cases which did not fall directly within them, the judges held that they were bound by the ordinance of Edward I., and refused to rectify the most palpable errors after the expiration of the term to which the record belonged. It is possible that the judges adhered thus closely to their interpretation from a reasonable regard to their own safety; for in the seventeenth year of Edward I. (1289), we find that king instituting a prosecution of enormous severity against the judges, and imposing fines amounting altogether to 70,000*l.* for imputed offences, connected, for the most part, with the erasure and alteration of the records. With this before their eyes (and it was an expedient very convenient for a monarch engaged in expensive wars to repeat for the purpose of replenishing his coffers), the judges were perfectly justified in erring on the side of caution, by adhering to the strict letter of the ordinance.

But this rigid abstinence from all alteration of the record was necessarily a great inconvenience in the administration of justice, and led in course of time to a series of legislative enactments, called Statutes of Amendment and Statutes of Jeofails (from the Norman-French, *j'ai faillé*), by the former of which, authority was given to amend certain specified errors; by the latter, the judges were empowered to proceed to judgment notwithstanding such errors. The first Statute of Amendment (14 Edw. III., c. 6, 1340) enacted that no process should be annulled by a clerical mistake in "writing one syllable or letter too much or too little; but that as soon as the thing was perceived by the objection of the party, or in other manner, it should be amended in due form, without giving any advantage to the party who objected to the mistake." The judges exhibited great reluctance to depart from the letter of the statute, and much discussion arose whether the statute, though it authorised the amendment of a letter or syllable, extended to the case of a total omission of a word. In a case in which this point was raised some years after the statute had been passed, the judges resolved to incur no personal danger by deciding it, but formally consulted the law-makers upon the meaning of the Act. "I went," says Chief Justice Thorpe, who describes this conference in a case in the 'Year Book' (40 Edw. III. c. 34), "together with Sir Hugh Green, to the Parliament, and there were twenty-four of the bishops and earls; and we demanded of them who made the statute, if the record might be amended; and the archbishop or metropolitan said, that it was a nice demand, and a vain question of them, if it might be amended or not; for he said that it might as well be amended in this case as if it were but one letter, for if a letter or a syllable fail in a word, it is no word; wherefore, if all the word fail, it may be amended as well as if it failed but of a letter or a syllable; for there is no more difference in the one case than in the other." Upon this advice of the archbishop, the judges admitted the amendment of a word.

In consequence of the indisposition of the judges to give this statute a liberal interpretation, it proved in a great measure ineffectual; for though its terms appear to extend to every part of civil or criminal proceedings, the judges construed the word 'process' strictly, and confined amendments to civil suits, and in them to errors in the process for the defendant's appearance, and for summoning the jury. If therefore a mistake of a word, syllable, or even a letter, was made by the clerk in drawing up the roll or body of the record, the whole proceedings might be annulled by a writ of error. To remove this, and to enlarge the power of judges in amendments, the statutes 8 Henry VI. c. 12 and c. 15 (1430) were made, by which the judges were authorised, "in any record, process, word, plea, warrant of attorney, writ, panel, or return, to amend all that which to them seemed to be the misprision of the clerk;" and also the "misprisions of sheriffs, coroners, bailiffs of franchises, or other officers, in their returns."

But these latter enactments, which were, properly speaking, the only statutes of amendment in ancient times (those which followed being statutes of Jeofails), though they considerably enlarged the power of the judges in making amendments, proved an insufficient relief to suitors. They extended only to the amendment of the misprision of the clerks, and upon this point subtle doubts and nice distinctions were suggested by the acuteness of legal criticism, and multiplied to an enormous extent in the course of the ensuing century; in consequence of which, judgments were continually overthrown by formal objections, founded on errors which the courts did not consider to be strictly clerical misprisions.

The next legislative provision was a Statute of Jeofails, passed in 1540 (32 Henry VIII. c. 30), by which it is enacted, that "where the jury have given their verdict for either party in any court of record, and a jeofail or mistake is afterwards discovered, the judgment of the court shall stand according to the verdict without reversal." This was followed by the statute 18 Eliz. c. 14 (1572), which declares, "that after verdict given in any court of record, judgment shall not be stayed or reversed for false Latin or other faults in form, in original and judicial writs, counts, &c., or for want of any writ, or by reason of the imperfect return of any sheriff, or for want of any warrant of attorney." The 21st Jac. I. c. 13 (1623) specifies several other formal defects not mentioned in the previous statutes, and declares, that on account of such defects, when discovered after verdict, no judgment shall be stayed or reversed. The next Statute of Jeofails, in chronological order, was the 16 & 17 Charles II. c. 8 (1665), called by Mr. Justice Twisden "the Omnipotent Act," which was intended to remove doubts arising upon former laws as to the distinction between matters of form and matters of substance, and also specified a great variety of minute technical defects, which after verdict were not to arrest or stay the judgment of the court. These statutes were calculated to aid imperfections in form after the verdict of a jury had passed upon the facts. This limitation was extremely unreasonable and prejudicial, as it enabled a party who made no defence, and had no substantial defence to make, to defeat a just action, by taking formal objections to the record, in arrest of judgment, or upon a writ of error, of which he could not have availed himself after a verdict. To remedy this inconsistency, the statute introduced by Lord Somers, after his retirement from the office of chancellor in 1705 (4 Anne, c. 16) extended the operation of the Statutes of Jeofails to all cases of judgment by confession or default.

From this summary view of the statutes, it appears that since the time of Henry VI. the legislature discontinued the direct and convenient mode of obviating the evil by allowing the judges to amend formal errors in their records where justice required it, and adopted a circuitous and uncertain course, by specifically enumerating certain errors and mistakes which were not to deprive the successful party of his judgment. Perhaps the caution of the judges in former times, in adhering rigidly to the letter of the power delegated to them, may have suggested this course to the legislature. However this may have been, there can be no doubt that the authority to amend under certain restrictions was the more efficient remedy. The Statutes of Jeofails have always given very imperfect relief to suitors; for professional ingenuity has never failed to discover new errors not specified in them, and to draw subtle distinctions in cases where the words of the statutes were to a common understanding distinctly applicable.

In modern times a disposition has been manifested to proceed upon the ancient course, by increasing the authority of the judges to make amendments. A most important improvement at the time was introduced by the statute of 9 Geo. IV. c. 15, which enabled "any court of record in civil actions, any judge at Nisi Prius, and any court of Oyer and Terminer and gaol delivery, if such court or judge should see fit so to do, to amend the record upon the appearance of a variance between any matter in writing or in print produced in evidence, and the recital thereof upon the record."

Further improvements, both in the pleading and practice of the courts, were effected by the 3 & 4 Will. IV. c. 42, §§ 23 & 24. But all former powers of amendment vested in the judges have been swallowed up, as it were, in the sweeping powers lately conferred on the courts by the Common Law Procedure Acts of 1852 and 1854, which not only enable amendments to be made in nearly all matters of merely technical detail, but require the judge at all times to make all such amendments as shall be necessary, so that the real question in issue betwixt the parties shall be tried in the existing suit. This statute also sweeps away several niceties in the practice of special pleading, which have for centuries been a fertile source of delay and expense, as well as caused frequently a positive defeat of justice; and it is somewhat curious, that practically the statute will to some extent cause a return to the ancient system of pleading *ore tenus*, for defective and erroneous pleadings are not to be objected to by special demurrers, which are abolished, but to be summarily amended by a judge at chambers, at the instance of the party objecting, and on such terms as to costs, answering the amended pleading, &c., as the judge shall determine.

In one of the early Statutes of Amendment (8 Henry VI. c. 12) indictments and criminal prosecutions are excepted from its operation;

and though there is no such exception in the other Statutes of Amendment, or in the Statutes of Jeofails, it was established by the current of authorities, that notwithstanding those statutes, criminal pleadings stood upon the same principles with respect to amendment as those to which all pleadings were subject at common law. With respect to indictments, it was considered that, as they are found upon the oath of a jury, there would be a manifest impropriety in making any alteration without their consent; hence it became a common practice to ask the grand jury, at the time of their returning their bills into court, whether they consented that the court should amend matters of form in the bills they had found, altering no matter of substance without their privity. Instances of such amendments are unknown in modern practice. Criminal informations, which do not depend upon the oath of a jury, may be amended by the court at any time before trial; though this was considered, as late as the time of Lord Holt, to be a questionable point. A frequent failure of justice by means of minute objections was the consequence of this exclusion of criminal cases from the beneficial operation of the statutes. An attempt to remove this evil was made in 1826, by the statute 7 Geo. IV. c. 64, in order, as the preamble states, "that the punishment of offenders might be less frequently intercepted in consequence of technical niceties." It provides that no judgment upon any indictment or information, for any felony or misdemeanour, whether after verdict of outlawry, or by confession, default, or otherwise, shall be stayed or reversed for want of the averment of any matter unnecessary to be proved; then proceeds to specify a variety of defects, and enacts that an objection founded on the appearance of such defects upon the record shall not have the effect of staying or reversing the judgment of the court.

But the whole mass of legal subtleties in indictable cases were swept away by the 14 & 15 Vict. c. 100, so that now criminal trials will be upon the merits, and on the merits only.

It would be out of place here to attempt to enumerate the various statutes passed to remedy defects in the administration of criminal justice. These can only be stated under the heads of the respective subjects to which they refer.

AMENDMENT, in Parliamentary Proceedings, is an alteration proposed to be made in the draught of any bill, or in the terms of any motion under discussion. Although no member (except when the House is in committee) is allowed to speak more than once upon the same question, he may speak again upon the amendment, which is considered so far a new question. Sometimes an amendment is moved, the effect of which is entirely to reverse the sense of the original motion; but when this is the object, it is more usual to move a negative. It not unfrequently happens, however, that the amendment proposes to leave out all the words of the original motion except the word "That," with which it commences, and to substitute others in their place. When a motion for the amendment of the House is made, it is always in the words, "That the House do now adjourn." If carried, the House adjourns to the next sitting day, unless a resolution shall have been come to previously, that at its rising it will adjourn to some other day. It is not competent, therefore, upon a motion for adjournment to move an amendment, specifying any day to which the House shall adjourn. It was long disputed whether, when an amendment was proposed to a motion after the previous question had been also proposed, it was necessary to withdraw the previous question before the amendment could be put; it was decided in the House of Commons on the 16th March, 1778, that it was necessary first to withdraw the motion for the previous question. An amendment may be proposed upon an amendment. It is commonly said that the rule is, when an amendment has been proposed, that the amendment is first put to the vote, and then the main question; but this is not exactly the practice of Parliament. There the general rule is, that the motion which has been first put and seconded, shall always be the first put from the chair; and, accordingly, when an amendment has been proposed, instead of the question that it shall be adopted being directly put, a vote is taken upon the question, "That the words proposed to be left out stand part of the question." If this motion is carried in the affirmative, the main question, which is really the same thing, is next put, and, of course, agreed to. But if the motion, "That the words proposed to be left out stand part of the question," is negatived, the words that were proposed in the amendment are substituted, as of course, and the main question thus altered is then put. So that, in point of fact, the amendment separately is never put at all.

When amendments are made in either House upon a bill which has passed the other, the bill, as amended, must be sent back to the other House. The rules of proceeding between the Houses, in the case of such amendments, are as follows:—"1st, Either House disagreeing to amendments made by the other should assign reasons, and all reasons must be delivered at a conference; 2ndly, If the reasons for disagreeing are held to be sufficient by the other House, that House answers by message that they do not insist; 3rdly, If held insufficient, the House at a conference say, that they insist, or adhere, and give reasons for so doing." It may be added, that the almost uniform practice in both Houses, when it is intended not to insist upon the amendments, has been to move affirmatively "to insist," and then to negative that question. As to the practice in passing bills in Parliament, see May's 'Treatise on the Laws, Usages, &c., of Parliament,' and 'The Standing Orders of both Houses,' published annually.

AMERCEMENT. Where courts of justice impose a pecuniary punishment, the sum ordered to be paid is termed a *fine*, or an *amercement*, according to the nature of the offence and the authority of the court. The difference between these is not merely nominal, though at the present day of no practical importance. The remedy for the recovery of an amercement is by action, or by distress; for a fine, the law has provided a process for securing payment, by arrest of the person.

Where the offence amounts to a breach of the peace, or to a contempt of court, a fine is the ordinary punishment, the amount of which is in the sole discretion of the judge: where the offence is of a lighter character, the party is punished by being amerced; and is said to be *in misericordiâ*, or 'at the mercy' of the court. In the latter case, the court has no further authority than to adjudge that *some* amercement shall be inflicted on the party; the *amount* of it the law leaves to be assessed (or, in technical language, *affeered*) by persons whose character is analogous to that of a jury.

Thus the sum ordered to be paid by way of penalty for the commission of any criminal acts, of which an offender has been found guilty, is a *fine*, and is sometimes also called a *ransom*, because it is imposed in lieu of corporal punishment.

So, anciently, where the defendant in a civil action had a verdict against him for the commission of a trespass, or any other civil injury accompanied by force or violence, the court awarded that he should pay a fine to the crown over and above the damages which he was liable to pay to the injured party. (Hence the origin of the former, and now abolished, proceedings called 'Levying a Fine,' to bar an estate tail.) Where there was a verdict in an action against the defendant for a breach of contract, or other similar injury wholly independent of any imaginable force or breach of the peace, the court awarded that he should be *amerced* (in addition to the usual judgment of damages, &c., payable to the plaintiff), and the proper person to assess the amount was the coroner of the county in which venue in the action had been laid. In actions in which the plaintiff failed in establishing his right, a similar amercement was imposed on him *pro falso clamore suo;* and this is in addition to the costs which he had to pay to the successful party.

Although the records of legal proceedings till quite recently carried on their face the formal evidence of these ancient usages, and the defeated plaintiff was nominally amerced for his false claim, and the unsuccessful defendant made liable in many instances to be amerced for his resistance to the plaintiff's just demand, yet in civil actions, neither fine nor amercement were ever in fact levied. In some cases the legislature had abolished the practice; in others it had been abrogated by desuetude, and therefore when new forms of proceedings were framed, after the passing of the Common Law Procedure act of 1852, the nominal amercement of the unsuccessful litigant was done away with. Scarcely any other fines or amercements are now known, except those which are imposed in the execution of criminal justice.

The subject of amercements was formerly of sufficient importance to obtain a place in the provisions of the 'Great Charter,' which enacts that they shall be equitably proportioned to the magnitude of the offence, and shall in no case be so excessive as to deprive the offender of the means of livelihood. It is by analogy to the case of amercement that fines, although not expressly named in 'Magna Charta,' are deemed to be constitutionally within its spirit, so as to restrain within moderate and reasonable limits the discretion of the judges in imposing them.

(*Bill of Rights*, 1 William and Mary; Bacon's *Abridgment*, tit. *Fines and Amercements;* Blackst. *Comm.* iii. p. 429.)

AMERICANISM, a term used to express some peculiarity in the written or spoken language of the inhabitants of the United States of North America. Of all the colonies of Great Britain, in which her language has been planted, the United States are yet the only parts that have been separated from the mother-country, and have attained political independence. In consequence of the rapid increase of their population, the diffusion of education, and the springing up of a numerous body of native writers, we see a new phenomenon in the history of the world, of two great nations separated by a wide ocean using the same language. To preserve this language in its purity, as far as its essential character is concerned,—to introduce no new words but such as experience shows to be necessary,—to form them on true principles of analogy, and to give to them precise and definite meanings—these are objects of equal importance to the two nations; for the preservation of a common language is a bond of unity, and one of the great elements of civilisation. The mother-country may yet claim—and perhaps her claim will be allowed by some Americans—the privilege of a very rigid examination of American importations, before she allows them to be current coin of the realm; but to attempt to reject all new words that America produces, would be both absurd and ineffectual. New wants and new circumstances are the parents of new terms, which increase quicker in a new than in an old country. The main differences between the spoken and written English language, as it exists in America and Great Britain, may be comprised under the following heads:—Pronunciation; the use of words now obsolete in England, or used in different senses; the use of words in various parts of America, as they are still used in various provinces of England; and new words.

As to the use of words now obsolete in England, they are mainly confined to conversation, for every one is aware that there is very little in the style of a good American writer, except perhaps a greater degree of ornament, by which we can distinguish it from that of a good English writer. But as the Americans write a great deal in public journals, and are the most prolific people in the world in producing inaugural speeches, orations, and all the various modes of addressing an audience, we should look at that part of their language in order to form a complete judgment of its whole condition, as well as at those specimens of composition which are of a less showy but more valuable and permanent nature.

The number of words now used in a different sense from that which they have in England is but small among writers of good authority; the list of those used in conversation would be somewhat larger. We have heard the word *shew* used as the past tense of the verb *to show;* the form is now obsolete in England, but may be found in our older writers. In some parts (for we are aware that in so extensive a country scarcely any remark of this kind can be general), the word *balance* in the spoken language is employed to express the *remainder*, or *the rest:* thus people speak of the "balance of the professors," meaning "the rest of the professors." The word *mutton* is sometimes used, as it once was in England, to signify a sheep. Dr. Webster remarks, that this sense is obsolete or ludicrous: it is not either obsolete or ludicrous in the spoken language of some districts. The word *bug* is used (see Webster) in its original sense of a *fly;* and the old verb *prògress*, which the Americans use very often, and pronounce *progréss*, is now beginning to be again adopted in its native country, though we think we could very well do without it. In judging how far words used in America in different significations from what they have in England have been sanctioned by authority, and established in the written language, we cannot perhaps take a better guide than Dr. Webster's 'Dictionary,' and we shall find the number by no means small. Cooper, in his 'Mohicans,' speaks of a "lake having *flowed* its usual banks." Webster sanctions this usage under a transitive sense of the word *flow*, which he makes equivalent to *overflow*. (See Webster's 'Dictionary,' under *flow;* and the example.) Against this usage we take the liberty of protesting. In the 'National Intelligencer,' March 2, 1826, we find—"for providing a jurisdiction *convenient* to the scene of almost all the shipwrecks;" this English-provincial and Irish use of *convenient* in the sense of *near* is properly omitted by Webster. The verb *rent* has the double meaning in Webster of *granting on lease*, as a proprietor does, and *taking on lease*, as a tenant does. *Nullification* is not in Webster, but has been defended on the ground of analogy, and by a reference to the use of *nullify* in Flavel. The usage of the word *locate* is familiar to all who read American papers or public documents: we say "that a man has *located* (that is, has selected, surveyed, and marked out) a hundred acres in Alabama." The word *expect* is often used in a strange sense in some parts of America, but certainly nearly altogether in conversation, as in the following instance given by Webster: "I *expect* it was." The American lexicographer justly condemns this usage, which is of provincial English origin. The word *guess* in the sense of *believe* is another conversational expression. The word *lengthy* some critics object to as being of American origin: we rather doubt if it be. Still it is a good word, well made, and well adapted to express the wearisomeness of listening to a long speech or discourse of any kind: we presume that in this, as in some other instances, the Americans did not call the word into use till they felt the absolute necessity of it. For other American usages which are somewhat peculiar, the reader may refer to the following words in Webster:—*wagon* (*waggon*); *stud-horse; subserve; clever* (Webster's account of the English use of this word is incomplete); *notify; graduated*, &c. The American uses of *creek, girdle, section*, &c., may be seen in Webster. *Firebar*, in Webster, for *five-barrel*, is a mere vulgarism. Mr. Pickering, in a work published at Boston in 1816, has traced a great number of words and phrases, which have been considered as Americanisms, to the counties of the mother-country. We recollect one word at present, which we can only trace to Holland. In Virginia, *waffel-cakes* are often made; a similar cake, with the same name, *waffel*, is very common in Holland.

There are some words of which the use is exclusively American, and are little understood in England. We select two of the most common. 1. *Bunkum*, the origin of which is thus described:—A member of the lower House of Congress, from a district which included the county of Buncombe (in which county he resided), whose style of speaking produced a very common effect of driving the members from the hall, was one day addressing the House, when, as usual, the coughing and sneezing commenced, and the members began to leave. He paused awhile, and assured the House that there need be no uneasiness on their part, and that for himself it mattered not how many left, for he was not speaking to the House, but to *Bunkum*. It is now understood to mean the constituent body, as distinguished from Congress. 2. *Caucus* is thus explained:—On the 2nd of March 1770, a quarrel took place at the premises of John Gray, a rope-maker, between a soldier and a man in the employ of Gray, and the former was severely beaten. Two affrays in consequence took place, in which the soldiers fired upon the people of the town, three of whom were killed and five wounded. These occurrences induced the rope-makers and calkers, whose occupations brought them in contact, to form a society, and at its meetings the most violent resolutions were passed against the British government and its agents in America. The tories, in derision, denominated these assemblies of the members of this society *calker* meetings; and the word in time became corrupted to *caucus*, which is the term still used in Boston to denote a general meeting of a party.

As to new words, the number used in the written language is not great. The word *bindery*, meaning "a place where books are bound," is in Webster. We believe it is a new, but it certainly is not a bad word. In American advertisements we observe the word *book* is generally prefixed: thus we might say, a *book-bindery*. *Sparse* is, for anything we know, a new word, and well applied; the Americans say a *sparse* instead of a *scattered* population, and we think the term has a more precise meaning than scattered, and is the proper correlative of *dense*. The danger of new words is, that the ignorant will use them without knowing their meaning, as we may observe in some of the inferior American newspapers. The number of new words that may be gradually creeping into the American spoken language, we suspect, is not inconsiderable. This arises in some measure from intermixture with foreigners, and must produce some effect, though it may not be much. We have heard the German word *plunder* vulgarly applied to baggage or heavy commodities. The term *cookie* also, used for a species of tea-cake, is evidently derived from the German *kuchen;* and filibuster is from the French, through the German, embodied entirely from flibuster, a buccaneer or pirate.

We suspect that many words of a moral import are beginning to vary considerably as to the signification attached to them in England and America. *Highminded*, a word not much used in Great Britain, rather implies something elevated or noble in *enduring:* in the conversation language, at least, of some parts of America, it is applied as a term of praise to *action* often impetuous, and sometimes unjust. *Lady* and *Gentleman* are terms that come under the same predicament, as to difference of import.

The orthography of the English language is liable to more change in America than in England: the Americans, as a general rule, do not observe orthography so strictly as the English, of which any reader of American papers may convince himself. We refer to American newspapers, because they are, more than in England, used as a common medium for addressing the public on all subjects, and form a large part of the reading of the community.

AMHA'RIC LANGUAGE has its name from Amhara, in Abyssinia, where it is or was spoken in its greatest purity. Inferior dialects of the Amharic are spoken in the provinces of Gojam, Angot, Efat, Shoa, Bagemder, Samen, &c. The Amharic is supposed to be meant by Agatharchides when he speaks of a language called Kámara. (Hudson, 'Geogr. Min.' t. i. p. 46.) The Amharic began to prevail in Abyssinia over the Geez language when Icon Amlak, about the year 1300, having overcome the Zagæan dynasty, ascended the throne of his ancestors, and removed the residence of the royal court from Axum to Shoa, where he had lived in exile. A knowledge of the Amharic enables a traveller to make himself understood in nearly every part of Abyssinia, although there are numerous dialects, of which no complete classification has yet been accomplished; of these the Tigré resembles much more the ancient ecclesiastical Ethiopic or the Geez language, than the Amharic. The Arabian writer, Makrizi, counts 50 dialects. It will be probably quite as difficult to define the exact number of Ethiopian, as of Arabic, modern Greek, and English dialects, or the number of languages in general. The king of Abyssinia, his councillors, ecclesiastics, monks, and every well-educated Abyssinian, know the Geez language, in which documents and letters are usually composed. Therefore the Geez is called *lesana matzhaf*, or *metzhafena*, that is, the language of letters or books.

The British and Foreign Bible Society have published a 'Psalterium Davidis Amharice,' London, 1833, large 18mo; and 'Novum Testamentum in Linguam Amharicam, vertit Abu Rumi Habessinus, edidit Thomas Pell Platt,' London, 1829, foolscap 4to. The New Testament and the Psalms have been circulated by Mr. Gobat and other missionaries in Abyssinia, and have been sometimes transcribed by the natives who could not be provided with printed copies. The French consul at Cairo, Asselin de Cherville, caused Abu Rumi, an old Abyssinian, who had been the instructor of Bruce and Sir William Jones, to translate the whole Bible into Amharic. This is the translation which is in the possession of the British and Foreign Bible Society. The circumstances under which they obtained it are detailed in their reports, and in the 'Christian Researches in the Mediterranean from 1815 to 1820,' by the Rev. W. Jowett, pp. 197—213.

The Amharic is said to be a degenerated Semitic dialect, the grammatical structure of which has preserved its character, though its lexicographical contents are mingled with African words. It is likely that the Amharic and other dialects of the Ethiopic are derived from the old Arabic of the Himyarites in Yemen. The Amharic adds to the twenty-six characters of the Geez seven others, which are mere modifications in order to express some characteristic sounds. The vowels are expressed by variations in the shape of the letters, so that each character or letter is in fact a syllable, being a consonant followed by a vowel, thus: *lă, lū, lī, lā, lē, lĕ, lo*. The Amharic, with other Ethiopic dialects, is written from the left to the right hand, like the European languages.

AMIDES. A class of chemical compounds derived from ammonia, by the replacement of one of its atoms of hydrogen by another body, either simple or compound:—thus, amide of potassium, or potassium amide, and acetamide may serve to illustrate this class of substances, and their relations to ammonia may be seen from the following comparison of their formulæ.

$$\underset{\text{Ammonia.}}{N\left\{\begin{matrix}H\\H\\H\end{matrix}\right.}\qquad\underset{\text{Potassiumamide.}}{N\left\{\begin{matrix}K\\H\\H\end{matrix}\right.}\qquad\underset{\text{Acetamide.}}{N\left\{\begin{matrix}C_4H_3O_2\\H\\H\end{matrix}\right.}$$

The inorganic amides, like potassium amide, are not numerous, but amongst organic compounds there is a large and important family of amides, of which acetamide (othylamide) may be regarded as a type. To these latter, Gerhardt has recently added two other classes of bodies, in which respectively two and three equivalents of hydrogen are replaced by a negative organic radical like othyl. These three descriptions of amides he terms primary, secondary and tertiary amides. Their relations to each other may be seen by the following formulæ:

$$\underset{\text{Acetamide.}}{\overset{\text{Primary Amide.}}{N\left\{\begin{matrix}C_4H_3O_2\\H\\H\end{matrix}\right.}}\qquad\underset{\text{Diacetamide.}}{\overset{\text{Secondary Amide.}}{N\left\{\begin{matrix}C_4H_3O_2\\C_4H_3O_2\\H\end{matrix}\right.}}}\qquad\underset{\text{Triacetamide.}}{\overset{\text{Tertiary Amide.}}{N\left\{\begin{matrix}C_4H_3O_2\\C_4H_3O_2\\C_4H_3O_2\end{matrix}\right.}}}$$

In the above amides, each single equivalent of hydrogen is replaced by a single equivalent of a *uniatomic* negative radical, but sometimes two equivalents of hydrogen in a double equivalent of ammonia are replaced by a *biatomic* radical, giving rise to what is termed a *diamide*. Thus oxamide is a compound of this description:

$$\text{Oxamide}\;\ldots\;N_2\left\{\begin{matrix}C_4O_4{}''\\H_2\\H_2\end{matrix}\right.$$

A *triamide* is formed when a *triatomic* radical replaces three equivalents of hydrogen in a triple molecule of ammonia. Thus citramide is a triamide, and has the formula

$$N_3\left\{\begin{matrix}C_{12}H_5O_8{}'''\\H_3\\H_3\end{matrix}\right.$$

The diamides and triamides have also representatives amongst the secondary and tertiary amides, but for a complete description of these and more complex amides the reader is referred to 'Traité de Chimie Organique, par M. Gerhardt.'

Sometimes one of the remaining equivalents of hydrogen in a primary amide, is replaced by a positive radical, forming an *alcalamide*. The *acetanilide* for instance is an alcalamide:

$$N\left\{\begin{matrix}C_{12}H_5\\C_4H_3O_2\\H\end{matrix}\right.$$

The most important group of amides is that consisting of the primary organic amides. They are produced: 1st, by the abstraction of a double equivalent of water from the ammonia salts of the monobasic organic acids; thus,

$$\underbrace{\left.\begin{matrix}C_4H_3O_2\\NH_4\end{matrix}\right\}O_2}_{\text{Acetate of Ammonia.}}=\underset{\text{Acetamide.}}{N\left\{\begin{matrix}C_4H_3O_2\\H\\H\end{matrix}\right.}+\underset{\text{Water.}}{\left.\begin{matrix}H\\H\end{matrix}\right\}O_2}$$

2nd. By the action of the chlorides of the negative radicals upon ammonia:

$$\underset{\text{Chloride of Othyl or Acetyl.}}{\left.\begin{matrix}C_4H_3O_2\\Cl\end{matrix}\right\}}+\underset{\text{Ammonia.}}{N\left\{\begin{matrix}H\\H\\H\end{matrix}\right.}=\underset{\text{Acetamide.}}{N\left\{\begin{matrix}C_4H_3O_2\\H\\H\end{matrix}\right.}+\underset{\text{Hydrochloric Acid.}}{\left.\begin{matrix}H\\Cl\end{matrix}\right\}}$$

3rd. By the action of ammonia upon the ethereal salts of the monobasic organic acids; for example,

$$\underset{\text{Acetic Ether.}}{\left.\begin{matrix}C_4H_3O_2\\C_4H_5\end{matrix}\right\}O_2}+\underset{\text{Ammonia.}}{N\left\{\begin{matrix}H\\H\\H\end{matrix}\right.}=\underset{\text{Acetamide.}}{N\left\{\begin{matrix}C_4H_3O_2\\H\\H\end{matrix}\right.}+\underset{\text{Alcohol.}}{\left.\begin{matrix}C_4H_5\\H\end{matrix}\right\}O_2}$$

The primary amides are, with few exceptions, either sparingly soluble, or insoluble in water, and generally volatile without decomposition. By ebullition with water, most of them re-assume its elements, and become converted into ammonia salts, by the converse of the first reaction given above for their formation. This decomposition is greatly facilitated by the presence of free acid or alkali. The primary amides possess neither acid nor alkaline qualities, the secondary amides generally redden litmus paper, and frequently form salts.

The following is a list of some of the most important amides with their formulæ:

PRIMARY AMIDES.

Acetamide	$N(C_4H_3O_2)H_2$
Propionylamide	$N(C_6H_5O_2)H_2$
Butyramide	$N(C_8H_7O_2)H_2$
Valeramide	$N(C_{10}H_9O_2)H_2$
Benzamide	$N(C_{14}H_5O_2)H_2$
Salicylamide	$N(C_{14}H_5O_4)H_2$
Acetanilide, or Phenylacetamide	$N(C_4H_3O_2)\,(C_{12}H_5)H$

PRIMARY DIAMIDES.

Oxamide	$N_2(C_4O_4)''H_4$
Succinamide	$N_2(C_8H_4O_4)''H_4$
Suberamide	$N_2(C_{16}H_{12}O_4)''H_4$
Asparagin	$N_2(C_8H_4O_6)''H_4$
Fumaramide	$N_2(C_8H_2O_4)''H_4$
Tartramide	$N_2(C_8H_4O_8)''H_4$

For the modes of producing the inorganic amides, see POTASSIUM-AMIDE, and ZINCAMIDE.

AMIENS, TREATY OF. [TREATIES, CHRONOLOGICAL TABLE OF.]

AMINES. [ORGANIC BASES.]

AMISATINE ($C_{96}H_{39}N_{11}O_{18}$), a crystalline body of no interest, obtained from indigo.

AMMELIDE ($C_6N_4H_4O_4 = NCyH_2, 2CyHO_2$), a chemical compound obtained by the action of concentrated sulphuric or nitric acid upon ammeline or melam.

$$\underbrace{2NCyH_2,\ CyHO_2}_{\text{Ammeline.}}+2HO=\underbrace{NCyH_2,\ 2CyHO_2}_{\text{Ammelide.}}+\underbrace{NH_3}_{\text{Ammonia.}}$$

$$\underbrace{3NCyH_2}_{\text{Melam.}}+4HO=\underbrace{NCyH_2,\ 2CyHO_2}_{\text{Ammelide.}}+\underbrace{2NH_3}_{\text{Ammonia.}}$$

Ammelide is a white powder, insoluble in water, alcohol, ether, and acetic acid, but soluble in warm solution of ammonia. It is also soluble in sulphuric, nitric, and hydrochloric acids, and when these latter solutions are boiled, the ammelide is transformed into cyanuric acid and ammonia. Ammelide possesses neither acid nor alkaline properties in a marked degree, nevertheless it forms a compound with silver, which has the formula $C_6N_4H_3AgO_4$.

AMMELINE ($C_6H_5N_5O_2 = 2NCyH_2, CyHO_2$), a body produced by the action of acids or alkalies upon melam or melamine: The following is the reaction:—

$$\underbrace{3NCyH_2}_{\text{Melam or Melamine.}}+2HO=\underbrace{2NCyH_2,\ CyHO_2}_{\text{Ammeline.}}+NH_3.$$

It is a brilliant white crystalline body, insoluble in water, alcohol, and ether, but soluble in several acids and in solutions of the caustic alkalies. It possesses feeble alkaline properties, uniting with most acids and forming crystallisable salts, which are, however, partially decomposed by water.

AMMON, or AMUN, or AMN RA, the name of an Egyptian deity, whom the Greeks considered as synonymous with their Zeus (Jupiter). He is often represented on the monuments of Egypt and in other works of Egyptian art with a ram's head and a human body; about which Herodotus (ii., 42) tells the following odd story, picked up during his travels in Egypt:—"Hercules was exceedingly anxious to have a sight of Zeus, but Zeus did not feel inclined to show himself. At last, when Hercules was very importunate, Zeus hit on the following contrivance: he flayed a ram, and cutting off the head put it before his face; he then got into the skin, and in this guise showed himself to Hercules. From this circumstance the Egyptians represent the image of Zeus with a ram's head."

The god Ammon appears in the human form with a tesher, or tall red cylindrical cap on his head, surmounted with two plumes. Also, under the figure of a crio-sphinx or ram-sphinx, which is an animal with a ram's head and the body of a beast of prey of the feline species. ('Egyptian Antiquities,' vol. i., in the 'Library of Entertaining Knowledge,' and the drawings in the French work on Egypt, 'Antiquities,' tom. iii., pl. 32.)

The word *Ammon*, or *Amun*, is probably connected with the Coptic word signifying 'to feed' sheep. ('Coptic Testament,' John xxi. 15; &c.) Ammon would thus be the god of a nomadic race, and originally a pastoral deity. Several other derivations, with the traditions on which they rest, agree in representing Ammon as a guide and protector, bearing the same relation to mankind as a ram to the flock.

The worship of Ammon seems to have been specially of Ethiopian origin, and its chief place to have been Meröe. Its introduction into Egypt was annually celebrated for twelve days at Thebes, when the image was carried across the Nile, and after an interval brought back, as if it had returned from Ethiopia. What power was worshipped under this form is yet doubtful, some contend that it was the sun,

others that it was the zodiacal sign Aries. The number twelve is further held to point to the astronomical character of Ammon and his place in the Zodiac; while he has also been described as the spirit of the universe and the author of all life. Sir J. G. Wilkinson's theory is, that the Egyptians had the idea of an abstract and supreme deity, "worshipped in silence," according to Jamblichus, but that the attributes of this deity were soon divided amongst a variety of gods, of whom they gave bodily representations. Ammon was the "divine mind in operation, the bringer to light of the secrets of its hidden will." Women of high rank are represented on Egyptian monuments as ministering in the temple of Ammon. The two chief Ammonian temples which now exist are that at Carnak, on the east side of the Nile, forming part of the extensive ruins of Thebes, and that of the oasis of Siwah, in the Libyan Desert, known to the Greeks by the name of Ammonium; this last has been described by Mr. Bayle St. John in his 'Adventures in the Libyan Desert,' 1851.

The Greeks adopted the worship of Ammon at an early period. There was a temple and statue, the gift of Pindar, erected to him at Thebes; Pindar also celebrates him in an ode. Other places where he is known to have been worshipped were Sparta, Aphylis, Megalopolis, and Cyrenaica. Alexander's visit to the Ammonium at Siwah is well known.

We find in Jeremiah xlvi. 25, and Ezekiel xxx. 15, the expression Amon-No; and in Nahum iii. 8, that of No-Amon, given as No only in the authorised translation. The former is supposed to refer to the Greek Diospolis, or 'City of Jupiter,' now forming part of the ruins of Thebes. The No of Nahum is more probably the Diospolis of the Delta.

The name Amon forms a part of the proper name of several Egyptian kings and persons, such as Amenotph and Ptamon; and is also often used in the title or qualifying term applied to the name of a king; thus we find on the monuments prefixed to the name of Ramses, the title *Amn-mai*, 'beloved by Ammon.'

[Jablonsky's *Pantheon*; J. C. Prichard's *Egyptian Mythology*; J. F. Champollion, *Panthéon Egyptien*; Ideler, *Handbuch der Chronologie*; Sir J. G. Wilkinson's *Ancient Egyptians*.]

AMMONIA (NH_3)—*Spirit of Hartshorn*—*Volatile Alkali*. This highly important compound was first procured in a pure state by Priestley, who termed it *alkaline air*; he obtained it from sal-ammoniac (chloride of ammonium), and hence the present name of the compound. Ammonia exists in the atmosphere to the extent of about one volume in 28,000,000 volumes of air; it occurs also in rain, river, and sea water, and is a product of volcanic action and of the putrefaction and decay of organic matters containing nitrogen. It is also formed during the destructive distillation of animal and vegetable substances; the chief source of our present supply of ammonia and its compounds being, in fact, the processes of illuminating-gas and bone-black manufacture. There results from these latter operations an aqueous liquor of an insupportable odour, termed *ammoniacal liquor*, which contains a considerable quantity of the carbonate and sulphide of ammonium; on the addition of hydrochloric acid to this liquor, these ammoniacal compounds are decomposed, and chloride of ammonium formed, together

with carbonic acid and sulphuretted hydrogen gases, which latter escape into the atmosphere.

$$\underbrace{NH_4O, CO_2}_{\text{Carbonate of ammonia.}} + \underbrace{HCl}_{\text{Hydrochloric acid.}} = \underbrace{NH_4Cl}_{\text{Chloride of ammonium.}} + \underbrace{CO_2}_{\text{Carbonic acid.}}.$$

$$\underbrace{NH_4S}_{\text{Sulphide of Ammonium.}} + HCl = NH_4Cl + \underbrace{HS}_{\text{Sulphuretted Hydrogen.}}.$$

When the chloride of ammonium thus formed is mixed with its own weight of slaked lime, and heat applied to the mixture, abundance of gaseous ammonia is evolved, and may be collected either in glass vessels over mercury or by the displacement of atmospheric air from inverted jars. [GASES, COLLECTION OF.]

$$NH_4Cl + \underbrace{CaO}_{\text{Lime.}} = \underbrace{NH_3}_{\text{Ammonia.}} + \underbrace{CaCl}_{\text{Cloride of calcium.}} + \underbrace{HO}_{\text{Water.}}.$$

Ammonia cannot be produced by the direct union of its elements; but when hydrogen is presented to nitrogen in the nascent state, the elements unite and form ammonia. This is the case when moistened iron filings are exposed either to air or to pure nitrogen.

Ammonia is also formed when zinc, iron, or tin is dissolved in dilute nitric acid.

Properties.—At ordinary temperatures and pressures ammonia exists as a colourless and invisible gas, possessing a powerful and extremely pungent odour and an alkaline taste. Its specific gravity is 0·5902, and 100 cubic inches weigh almost exactly 18 grains.

Mr. Faraday ('Phil. Trans.' 1823, p. 189) found, that by subjecting ammoniacal gas to a pressure of about $6\frac{1}{2}$ atmospheres, at the temperature of 50°, it became a colourless transparent liquid, the density of which was 0·760, water being 1.

An animal plunged into ammoniacal gas is immediately killed, and a taper when immersed in it is extinguished: it appears, however, to be slightly inflammable; for the flame is rather enlarged before it goes out, and a small jet of the gas may be burned in oxygen.

Dr. Priestley found that, by moderate degrees of heat, ammoniacal gas is merely expanded; but when passed through an ignited porcelain tube, it is decomposed, and, increasing to double its volume, rendered inflammable. ('Experiments on Air,' vol. ii. p. 393.) He also first proved that it is decomposed by the electric spark, and separated into hydrogen and nitrogen gases (vol. iii. p. 389). These experiments have been repeated by Berthollet, Davy, and Gay-Lussac. Dr. Henry ('Annals of Philosophy,' N. S., viii. p. 347) also found that when ammoniacal gas is exposed to a current of electric sparks, its volume is exactly doubled, and it is resolved into three volumes of hydrogen gas, and one volume of nitrogen gas. As the result of these experiments it is obvious that ammoniacal gas is a compound of three volumes of hydrogen and one volume of nitrogen gas, the four volumes being condensed to two: by weight it is composed of

Three atoms of hydrogen $1 \times 3 =$	3	or per cent.	17·64
One atom of nitrogen . .	14	„ „	82·36
Weight of the atom . . =	17		100·

That this is the composition of the gas in question is also shown by comparing its calculated and actual density. According to Dr. Thomson ('Chemistry of Inorganic Bodies,' vol. i. p. 704), 300 cubic inches of hydrogen gas weigh 6·4842 grains, and 100 cubic inches of nitrogen gas weigh 30·2794 grains, making together 36·7636 grains; but during combination the gases condense to half their volume, consequently 200 cubic inches of ammoniacal gas weigh theoretically 36·7636 grains, and 100 weigh 18·3818. Now, according to Allen and Pepys the weight by actual experiment is 18·18 grains, which is sufficiently near the calculated statement to prove its correctness.

Ammonia is powerfully alkaline, restoring the blue colour to reddened litmus, turning turmeric paper reddish-brown, and perfectly neutralising the strongest acids forming the different salts of ammonia.

Water dissolves ammoniacal gas with great rapidity, and in large quantity; a few drops of water thrown up into a jar of the gas instantly condense it; a piece of ice also immediately liquifies in and condenses the gas. Water at 50° is capable of condensing 670 times its volume; the density of the solution diminishes as its strength increases, so that, according to Davy, with whom other chemists nearly agree, when water contains $9\frac{1}{2}$ per cent. of ammonia, its density is 0·9692; but when it holds $32\frac{1}{2}$ per cent., it is reduced to 0·8750. The aqueous solution is colourless, transparent, and has the pungency and alkaline property of the gas; by exposure to the air, the ammonia partially escapes, and by the application of heat it is expelled from the water; on account of this volatility of ammonia, vegetable colours which have been altered by it regain their original tints as it evaporates, which is not the case when the change has been caused by the fixed alkalies.

The annexed table shows the percentage of ammonia in aqueous solutions of the gas of different specific gravities :—

Specific Gravity.	Ammonia in 100 parts by weight.	Specific Gravity.	Ammonia in 100 parts by weight.
0·8750	32·50	0·9435	14·53
0·8875	29·25	0·9476	13·46
0·9000	26·00	0·9513	12·40
0·9054	25·37	0·9545	11·56
0·9166	22·07	0·9573	10·82
0·9255	19·54	0·9597	10·17
0·9326	17·52	0·9619	9·60
0·9385	15·88	0·9692	9·50

The presence of ammonia may be detected by its strong odour, by holding moistened turmeric paper where it is suspected to exist, and by the formation of a white vapour, when exposed to a glass rod moistened with hydrochloric acid. Ammonia can only thus be recognised when it is in the free state, and therefore, in testing for it, caustic soda or quicklime should be added to the solution, in order to liberate the ammonia from its combination with any acids that may be present.

Ammonia is used for many purposes, both in medicine and in scientific chemistry; as, however, it would be impossible in some cases, and inconvenient in almost every one, to employ it in its gaseous state, it is used in solution in water, and then frequently called *liquid ammonia:* but this term can be applied with propriety only to the gas rendered fluid by cold or pressure. Solution of ammonia may be readily prepared by mixing chloride of ammonium with lime, in the mode and proportions already mentioned, and passing the gas liberated into water: this may be done either by inserting a glass tube bent at right angles into the mouth of the retort, and then putting the other end into a bottle of water; or, which is better, in case absorption should take place, a tubulated receiver may be used instead of the bent tube, securing it properly by a perforated cork to the retort, and luting it so that it may withstand the pressure caused by passing the gas into the water. Alcohol also dissolves a large quantity of ammonia.

We shall now briefly notice the nature and results of the action of ammonia upon certain elementary bodies. It has been already stated that ammoniacal gas may be burned in oxygen gas: a mixture of these gases may also be fired by the electric spark, the results being water and nitrogen gas; a little nitric acid is also generated, if the quantity of oxygen gas be more than sufficient to combine with all the hydrogen of the ammonia. (Dr. Henry, 'Phil. Trans.,' 1809.) Chlorine gas, by mere admixture with ammonia, decomposes it completely, and the action is attended with the evolution of light and heat. The chlorine combines with the hydrogen of the ammonia; hydrochloric acid is thus formed, which uniting with the ammonia remaining undecomposed, the result is chloride of ammonium, while nitrogen gas is liberated. The same effects are obtained if the aqueous solutions of the gases in question be employed; but then the changes are unaccompanied by light or heat.

Ammonia has no action upon carbon, except at a high temperature; if however a piece of well-dried charcoal be passed up into ammoniacal gas over mercury, it is capable of absorbing ninety times its volume in twenty-four hours. The gas undergoes no chemical change, and from Saussure's experiments it appears that the absorption is analogous to the capillary attraction of liquids by very small tubes. Sulphur, when strongly heated in ammoniacal gas, partially decomposes it, and sulphide of ammonium is one of the products. At a high temperature, phosphorus also decomposes ammonia, and phosphuretted hydrogen is formed; when no heat is employed, phosphorus absorbs the gas, and a deep brown-coloured substance is formed, which is almost pulverulent: its properties have not been examined. Iodine and ammonia, if put in contact with water, form the well-known detonating substance *iodide of nitrogen*, generally prepared by putting iodine into the aqueous solution of ammonia.

The action of the metals upon ammonia varies considerably, according to their nature. Gay-Lussac and Thénard have shown that potassium and sodium absorb ammoniacal gas, and are covered with a white crust. The absorption is more rapid when the heat of a spirit-lamp is employed; the white crust becomes deep yellow, the surface of the metal is brilliant and smooth, whilst the new compound is greenish, fuses, and runs upon the sides of the tube; when the operation is continued until the potassium entirely disappears, ammoniacal gas is not only absorbed, but a portion is decomposed and hydrogen gas given out. The compound formed is of a deep olive-green colour, its fracture crystalline, and its density greater than that of water. It fuses at a temperature higher than boiling water, does not conduct electricity, burns in oxygen gas, and yields hydrate of potash and nitrogen gas. Water decomposes it rapidly; the results are potash and ammoniacal gas. [POTASSIUMAMIDE.]

When ammoniacal gas is passed over ignited iron or copper, the density of the metals is much dimished; and by the repeated action and decomposition of the gas, iron may be increased in weight, as proved by Despretz, 11·5 per cent., which increase is owing to the absorption of nitrogen by the metal.

Ammonia, Salts of.—The general properties of the salts of ammonia are as follow: soluble in water, with few exceptions; decomposed by the fixed alkalies and alkaline earths, with the evolution of ammonia; decomposed when a magnesian salt and a soluble phosphate are added to them, a crystalline precipitate being formed, which is a double salt, composed of phosphate of ammonia and magnesia; decomposed and dissipated by heat, unless the acid, like the phosphoric or boracic, be a fixed one, in which case the ammonia is expelled, and the acid remains. A solution of chloride of platinum occasions a yellow precipitate in concentrated solutions of ammoniacal salts.

A few of the more important salts of ammonia are described below.

Ammonia, Carbonates of.—Several carbonates of ammonia exist; the most important are the sesquicarbonate and the bicarbonate.

Ammonia, sesquicarbonate of ($2NH_4O, 3CO_2$).—This salt is contained in the *Pharmacopœia* under the incorrect name of *Ammoniæ subcarbonas*, or *subcarbonate of ammonia*. It is directed to be prepared by heating, in a subliming vessel, a mixture of one part of chloride of ammonium, or sal-ammoniac, and one part and a half of carbonate of lime or chalk; it is however usually and more economically obtained by decomposing sulphate of ammonia with carbonate of lime. In this case, double decomposition ensues; sesquicarbonate of ammonia is formed, volatilised, and is condensed in the upper part of the vessel, while sulphate of lime remains in the lower.

Sesquicarbonate of ammonia is a colourless, translucent, moderately hard salt. It has a pungent smell, and a sharp, penetrating taste. It is soluble in about four times its weight of cold water, and is decomposed by hot water. It acts upon vegetable blues and yellows, like an alkali; and on this account, as well as its ammoniacal smell, has been called a subcarbonate.

It is composed of

Three atoms of carbonic acid	66
Two atoms of ammonia	34
Two atoms of water	18
Atomic weight	118

As three atoms of carbonic acid are combined with two atoms of ammonia, and these being as one and a half to one, this salt, like others similarly constituted, is generally termed a *sesquicarbonate*.

It is used in medicine as a stimulant, and usually called *smelling salts*. It is also employed as a substitute for yeast in making some of the finer kinds of bread. As a chemical reagent, it is extensively used; and also for preparing various other ammoniacal salts.

Ammonia, bicarbonate of ($NH_4O, CO_2 + HO, CO_2$).—This salt may be prepared by passing carbonic acid gas into a solution of sesquicarbonate of ammonia, in which way it may be obtained in crystals; by heating a mixture of equal weights of chloride of ammonium and carbonate of lime in a subliming vessel; or lastly, and with the greatest facility, by exposing powdered sesquicarbonate of ammonia to the air until it becomes inodorous; in this case, a larger proportion of ammonia escapes than remains, and the residue thus becomes a bicarbonate. When obtained by sublimation, it resembles the sesquicarbonate in appearance, but differs from it in being devoid of pungency; it is rather hard, soluble in cold, and decomposed by hot water. When perfect, it has no alkaline action on vegetable colours, like the preceding carbonates. The salt obtained by sublimation, or by exposing the sesquicarbonate to the air, consists of

Two atoms of carbonic acid	44
One atom of ammonia	17
Two atoms of water	18
Atomic weight	79

It is rarely used, either in medicine, or as a chemical reagent.

Ammonia, nitrate of ($NH_4O\,NO_5$).—A salt best obtained by saturating nitric acid with sesquicarbonate of ammonia. On evaporating the solution the salt crystallises in long prisms which are anhydrous. It is somewhat deliquescent, readily soluble in cold water, and when heated to 480° it is decomposed into protoxide of nitrogen and water. Hence its use for the preparation of protoxide of nitrogen.

Ammonia, sulphate of ($NH_4O\,SO_3, HO$).—A salt of ammonia prepared on a large scale by neutralising *gas-liquor* or *bone-liquor* with sulphuric acid and then crystallising. In small quantity, it is best made by saturating dilute sulphuric acid with sesquicarbonate of ammonia. The solution is colourless, and by evaporation yields small prismatic crystals; these have a saline taste, and are readily dissolved by water.

Crude sulphate of ammonia is largely employed in agriculture—either alone as a top-dressing, or as a constituent of artificial manures. It powerfully stimulates the growth of cereal, grass, and root crops.

AMMONIA, *Medical properties of.* This alkali is distinguished from the others by the appellation of Volatile, because at the ordinary temperature and pressure of the atmosphere it never exists in a fixed state, but either in a gaseous form, in which case it immediately combines with any carbonic acid which it encounters in the air, or is absorbed by water or spirit, from both of which it is easily liberated, particularly if heat be applied. Having been formerly obtained by distillation of shavings of hartshorn or other animal matters, it is familiarly known under the name of Spirit of Hartshorn. The combinations with carbonic acid have the same properties as the pure alkali, in respect to volatility, and only a diminished degree of causticity.

The gas in an undiluted state is highly pungent, with a suffocating odour, is irrespirable, and irritates and inflames the animal tissues. (Christison.) Diluted by passing through the air, from which it absorbs moisture and carbonic acid, which serve further to lessen its acrimony, it is occasionally, but rarely, applied to the eyes, in some passive inflammations, and to keep up vigilance in cases of somnolence from narcotic poisons. This last mode of using it is scarcely to be recommended, as dangerous inflammation of the eyes may subsequently follow. Indeed all employment of even the less caustic forms of administration, when much insensibility exists, such as in faintings, epileptic fits, or from narcotic poisons, likewise in experiments on persons in the state termed mesmeric coma, requires great care. Fatal inflammation of the windpipe has ensued by merely holding carbonate of ammonia (smelling salts) or a handkerchief dipped in strong aqua ammoniæ under the nostrils. (Nysten.) When it is to be introduced into the stomach, this should be done by means of the stomach-pump, to avoid any of it passing into the windpipe. Besides its local action, exciting inflammation and its effects, ammonia is itself poisonous, its secondary effect on the nervous system, particularly the spinal column, being sufficient to cause tetanic convulsions. Though Eau de Cologne may be grateful to adults, the vapour is unsafe for children. (See 'Lancet' for April, 1844.)

Ammoniacal gas absorbed by water constitutes the *aqua* or *liquor ammoniæ*. This is formed of two different degrees of strength: the one of a density of 882 at 62° F. called *fortior*, much too strong for any medicinal purpose, and only employed for some chemical purposes; the other of the density of 960, which also generally requires to be diluted further with water when intended for internal use, or with oils for external use, as it is very frequently, to form rubefacient liniments. The solution of the carbonate is likewise frequently employed in combination with oils. These, if long applied, or frequently repeated, cause inflammation which terminates in suppuration and ulceration.

Ammonia, when suitably diluted so as to be taken into the stomach, causes a feeling of warmth, with increased energy of the nervous power. Hence it acts as a prompt and valuable counter-poison to prussic acid, the bites of serpents, and the poison of many diseases, such as cholera asiatica, and typhoid fevers, at the commencement of which great depression of the nervous system is observed. In lesser degrees of depression, such as the languor of hysterical females, or in atonic gout, ammonia or its carbonates are daily resorted to. It is likewise employed to counteract acidity in the stomach. It must not be overlooked however that the long continued use of ammonia produces the same ill effects as the other alkalies when taken in excess. [ALKALIES.]

The salts of ammonia require a brief notice. The properties of the different combinations of ammonia with carbonic acid are too similar to those of the pure alkali to be noted separately, except to state that carbonate of ammonia furnishes a good emetic in the earliest stage of fever with great depression, and is in smaller doses given freely throughout adynamic fevers, sometimes in the effervescing form, especially when action of the skin is desired. Citric acid is employed to cause it to effervesce.

Hydrochlorate of ammonia is little employed in this country internally, but it may be beneficially used in combination with cinchona bark in fevers. In large doses it is poisonous. It is however chiefly employed to form discutient and evaporating lotions in conjunction with vinegar and spirit. For these it is most valuable, at the moment of solution.

Acetate of ammonia has little of the causticity of the pure alkali or the carbonates, neither is it volatile. It is so deliquescent that it cannot be kept in the solid form, and is always administered in weak acetic acid. This forms a most grateful refrigerant at the commencement of slight inflammatory complaints, and if the patient be kept warm, generally induces perspiration. For this purpose it requires to be freely given. It is also a diuretic, but not much employed. Properly diluted with rose-water it forms a cooling eyewash, most grateful after some forms of inflammation, to relieve the turgescence which remains, or even to remove turgescence which has not been preceded by inflammation. Scarpa thought it useful against commencing amaurosis.

AMMONIAC (GUM), a concrete juice produced in Persia, Abyssinia, &c., but the plant from which it is obtained does not appear to have been ascertained. Willdenow refers it to the *Heracleum gummiferum*, in which he is followed by the British College of Physicians. Others refer it to the *Ferula orientalis*. It consists of grains of various sizes, usually called *tears*: they are either separate or agglutinated into masses; their colour is whitish, but they become yellow by the action of the air; they are shining, opaque, irregular in shape, and more or less globular. When cold, ammoniac is rather hard and brittle; it softens by the heat of the hand, but does not entirely liquify at a stronger heat. The smell is peculiar and disagreeable, and the taste is nauseous, at first mucilaginous and bitter, and afterwards acrid. Its specific gravity is 1·207. When triturated with water, it is partly dissolved, forming an emulsion which becomes clearer on standing. When distilled with water, it loses its volatile oil, and becomes inodorous; the distilled water has the odour of the gum, and small drops of limpid, colourless oil float on its surface. Alcohol takes up about half its weight, forming a brownish-yellow solution, which becomes turbid when mixed with water. It is combustible, burning with a white flame, little smoke, and a strong smell; the ashes left consist of small portions of the carbonates of potash and lime, and phosphate of lime.

Sulphuric acid readily dissolves ammoniac, and water precipitates the solution; nitric acid converts it into a bitter substance; the fixed alkalies form with it a turbid solution, which is extremely bitter.

According to Bucholz, ammoniac consists of

Resin	72·0
Gum	22·4
Bassorine	1·6
Volatile oil, water, and loss	4·0
	100

It is used in medicine as a stimulant and expectorant.

AMMO'NIACUM—*Medical properties of.* This gum-resin is correctly referred to the *Dorema ammoniacum* (Don, in 'Linnæan Trans.,' vol. xvi. p. 599), which was discovered by Lieut.-Col. Wright, growing near Yezd Khâst, a town of Irâk Ajemi, the ancient Persis, about 42 miles south of Ispahan. Its Persian names are Ooshk and Ooshook. It has more recently been found on the low hills near Herat, likewise abundantly in Syghan, near Bameean, on the north-west slope of the Hindu-Coosh range of mountains. (Christison.)

Ammoniacum was known to the ancients: but it is supposed that what they used came from Africa as well as Asia, and was procured from a species of Ferula, *F. tingitana* (Linn.)

The Persian plant yields the juice chiefly from the stalk, especially the points of divarication of the umbels, owing to the punctures of numerous coleopterous insects. "The gum is so abundant, that upon the slightest puncture being made, it instantly oozes forth, even at the ends of the leaves." (Capt. Hart, 'Trans. of Medical Society of Calcutta,' vol. i. p. 369.) The juice quickly dries, and is either picked off or allowed to accumulate till it falls on the ground. This collection takes place about the middle of June. A tenth part is remitted as tribute to the government; the rest is sent to Bushire, on the Persian Gulf, and thence to Europe. The best comes by Bombay. The juice of the Syghan plant is obtained by making successive slices of the root, as in the case of assafœtida. The samples vary much in quality. The directions given to purify the inferior sorts, by softening them in boiling water, and squeezing them through a cloth, though capable of removing mechanical impurities, impair the power of the gum-resin, by driving off the volatile oil, which even in good specimens is not very abundant, 32 ounces yielding by distillation only one drachm.

The officinal form for administering ammoniacum is the *mixture*, in which it is partially dissolved and partially suspended in water. It is a most valuable expectorant, and may have its virtues increased by the addition of squills or ipecacuanha. Dilute nitric acid greatly heightens its powers. It is also an ingredient in the compound squill pills. Externally it is applied as a plaster, to disperse indolent swellings, either softened by vinegar, a form which has kept its place amid all the changes in medical agents for nearly 2000 years, or combined with mercury, which is often beneficial.

AMMONITES, a nation descended, according to Gen. xix. 38, from the incestuous connection of Lot with his younger daughter, about the year 1898 B.C. The name of their progenitor, *Ben Ammi*, means *son of my kindred*, and the name *Ammon* has nearly the same signification. The Ammonites, or the children of Ammon, are called by the Septuagint and Josephus, Ammanitæ. The country which they inhabited was situated between the rivers Arnon and Jabbok, north-north-east of the Moabites, and east of the tribes of Reuben and Gad. The Israelites, under Moses, smote the Amorites, and possessed their land from Arnon unto Jabbok, even unto the children of Ammon, about the year 1452 before Christ: but they did not enter the territory of the Ammonites, for the border of the children of Ammon was strong. (Num. xxi. 24.) The Israelites were directed not to distress the children of Ammon, because the Lord had given the land unto the children of Lot for a possession. The Ammonites, however, showed the Israelites no kindness while passing through the country, and they were therefore forbidden 'entering the congregation of the Lord.' Their active hostility is first mentioned in Judges iii. when they helped Eglon, king of Moab, to subjugate Israel, and their hostile feelings continued. They sustained, in consequence, a severe defeat from Jephthah. (Judges xi.) The history of the wars between the Israelites and the Ammonites are recorded in the Pentateuch and other books of the Old Testament, and in the book of Maccabees.

From the prophetic writings we derive some further information as to the history and character of the Ammonites. Their destruction is predicted by Isaiah xi. 14; Zephaniah ii. 9; Jeremiah xlix. 1-5; Ezekiel xxv. In the days of Justin Martyr, the Ammonites were still very numerous; and in the days of Origen, the Ammonites and Edomites went under the general name of Arabians.

Their metropolis was Rabbah. The surrounding country was called Arabia Philadelphiensis.

The Ammonites were uncircumcised (Jer. ix. 26), and worshipped Molech or Milcom, and their idolatry was, by the Ammonitish wives of Solomon, introduced among the Israelites. (1 Kings xi. 7, 33; 2 Kings xxiii. 13.)

Of their kings, we know only Nahash and Hanun, in the time of David; and Baalis, contemporary with Nebuchadnezzar. (Jer. xl.)

AMMONIUM. (NH_4). The hypothetical compound radical of the salts of ammonia. When ammoniacal gas unites with acids to form salts, the latter are regarded as no longer containing NH_3, but as compounds of the radical NH_4. Thus, when ammoniacal gas unites with hydrochloric acid, the salt chloride of ammonium is formed, containing the radical in question united with chlorine.

$$NH_3 + HCl = (NH_4)\,Cl.$$

In like manner, when ammoniacal gas unites with a hydrated oxyacid, it is supposed that the water of hydration of the acid coalesces with the body, NH_3, so as to form oxide of ammonium, which then unites with the acid to form a salt of ammonia. Thus, ammoniacal gas and hydrated nitric acid form nitrate of ammonia, $NH_3 + HO, NO_5 = (NH_4)O, NO_5$. In the salts of ammonia, therefore, the radical ammonia takes the place of the metal in ordinary metallic salts; and nitrate of ammonia, and chloride of ammonium, for instance, thus become analogous in their constitution to nitrate of potash and chloride of potassium.

Nitrate of potash	KO, NO_5
Nitrate of ammonia	$(NH_4)O, NO_5$
Chloride of potassium	KCl
Chloride of ammonium	$(NH_4)Cl$

This view, first suggested by Ampere, and subsequently applied by Berzelius, is frequently termed the *ammonium theory*. Ammonium has never been obtained in a separate state, and is probably incapable of existing free from any other body. Reasoning from the analogy of its compounds with those of the metals, it has by some been regarded as a true metal; but although its compound with mercury [AMALGAM] lends some support to this notion, yet the non-metallic character of other isolated radicals renders the metallic attributes of ammonium highly improbable.

Acetate of Ammonia (NH_4O, $C_4H_3O_3$).—This salt is prepared by adding sesquicarbonate of ammonia to dilute acetic acid. Owing to the superior affinity of the acetic acid for ammonia, the carbonic acid is expelled from it with effervescence, and a colourless solution remains, which contains neutral acetate of ammonia, but which, when concentrated and placed under the exhausted receiver of an air-pump over sulphuric acid, loses ammonia and yields transparent prismatic crystals, which are very deliquescent, and consist of an acid salt. The neutral salt may be obtained in the crystalline form by saturating glacial acetic acid with ammoniacal gas. It is white, and very soluble in water and in alcohol.

Acetate of ammonia is directed to be prepared in the 'London Pharmacopœia,' and kept in solution under the name of *Liquor Ammoniæ Acetatis*. It is used externally as a refrigerant, and internally as a diaphoretic, and is commonly known by the name of *Spirit of Mindererus*.

Oxalate of Ammonia (C_4O_6, $2NH_4O$, $+2$aq.).—This salt is prepared by adding sesquicarbonate of ammonia to a solution of oxalic acid, until it is saturated. The solution by evaporation yields small prismatic crystals; these are devoid of smell, have a bitter, saline taste, and dissolve readily in water. By dry distillation they yield oxamide. Oxalate of ammonia is used as a test of the presence of lime, and to precipitate it from solution in chemical analyses.

AMMONIUM, CHLORIDE OF. (NH_4Cl.) This salt has been long known, and extensively used, under the name of *Sal Ammoniac*. The substance from which it was first procured, was the soot of camel's dung. It is now largely manufactured in Europe, by combining hydrochloric acid, either directly or indirectly, with the ammonia obtained from the decomposition of animal matter, but principally from the liquor obtained during the preparation of coal-gas. This impure ammoniacal liquor is at once saturated with hydrochloric acid, and evaporated to crystallisation. The crystals are then sublimed.

Chloride of ammonium, as obtained by sublimation, is an amorphous, translucent, colourless salt; but when separated from water by crystallisation, its form is cubic. It has a sharp, saline taste, but no smell, and dissolves readily in water; exposure to a dry air produces no change in it; by heat, it volatilises without decomposition. Lime and the fixed alkalies decompose it, evolving ammoniacal gas; and sulphuric acid expels hydrochloric acid gas. It is composed of equal volumes of hydrochloric acid gas and ammoniacal gas, as may be shown by the perfect condensation of these proportions in a jar over mercury; or by weight, of

One atom of hydrochloric acid	36·5
One atom of ammonia	17.0
Atomic weight	53·5

This salt is much employed in the tinning of iron, copper, and brass, and in agriculture. It is generally used for preparing ammoniacal gas, and the sesquicarbonate of ammonia, in the modes already described.

AMMONIUM AMALGAM. [AMALGAM.]

AMMONIUM, IODIDE OF (NH_4I). Prepared by saturating a solution of hydriodic acid with ammonia, and then evaporating until the salt crystallises. Iodide of ammonium crystallises in cubes which are deliquescent, and is slowly decomposed on exposure to air and light. It ought, therefore, to be preserved in well stopped and opaque bottles. It is easily soluble in water, and also in alcohol and ether. The latter property has led to its extensive use in photography for iodising collodion. Iodine is very soluble in an aqueous solution of iodide of ammonium.

A'MNESTY is a word derived from the Greek *ἀμνηστία, amnēstia*, which, literally, signifies nothing more than non-remembrance. The word *amnestia* is not used by the earlier Greek writers; but the thing intended by it was expressed by the verbal form (*μὴ μνησικακεῖν*). The word ἀμνηστία occurs in Plutarch and Herodian. Some critics suppose that Cicero ('Philipp.' i. 1) alludes to his having used the word; but he may have expressed the thing without using the word *amnestia*. It occurs in the life of Aurelian by Vopiscus (c. 39), according to some editions in the Latin form, but it is possible that Vopiscus wrote the word in Greek characters, and it is doubtful whether the word was ever incorporated into the Latin Language. Nepos, in his life of Thrasybulus (c. 3), expresses the notion of an act of Amnesty by the words "lex oblivionis," and it is clear from a passage in Valerius Maximus (iv. 1), that the word was not adopted into the Latin language when Valerius wrote, whatever that time may be.

The notion of an amnesty among the Greeks was a declaration of the person or persons who had newly acquired or recovered the sovereign power in a state, by which they pardoned all persons who composed, supported, or obeyed the government which had been just overthrown. A declaration of this kind may be either absolute and universal, or it may except certain persons specifically named, or certain classes of persons generally described. Thus in Athens, when Thrasybulus had destroyed the oligarchy of the Thirty Tyrants, and had restored the democratical form of government, an exceptive amnesty of past political offences was declared, from the operation of which the Thirty themselves, and some few persons who had acted in the most invidious offices under them, were excluded. (Xenophon, 'Hellen.' ii, 4, 38; Isocrates, 'Against Callimachus,' c. 1.). So when Bonaparte returned from Elba in 1815, he published an amnesty, from which he excluded thirteen persons, whom he named in a decree published at Lyon. The act of indemnity, passed upon the restoration of Charles II., by which the persons actually concerned in the execution of his father were excluded from the benefit of the royal and parliamentary pardon, is an instance of an amnesty from which a class of persons were excepted by a general description and not by name. Of a like nature was the law passed by the French Chambers in January, 1816, upon the return of Louis XVIII. to the throne of France after the victory at Waterloo, which offered a complete amnesty to "all persons who had directly or indirectly taken part in the rebellion and usurpation of Napoleon Bonaparte," with the exception of certain persons, whose names had been previously mentioned in a royal ordinance as the most active partisans of the usurper. It was objected to this French law of amnesty, that it did not point out with sufficient perspicuity the individuals who were to be excepted from its operation. Instead of confining itself to naming the offenders, it excepted whole classes of offences, by which means a degree of uncertainty and confusion was occasioned, which much retarded the peaceable settlement of the nation. "In consequence of this course," says M. de Châteaubriand in a pamphlet published soon after the event, "punishment and fear have been permitted to hover over France; wounds have been kept open, passions exasperated, and recollections of enmity awakened." The act of indemnity, passed at the accession of Charles II., was not liable to this objection, by the distinctness of which, as Dr. Johnson said, "the flutter of innumerable bosoms was stilled," and a state of public feeling promoted, extremely favourable to the authority and quiet government of the restored prince.

AMO'MUM—*Medical Properties of this and allied Genera*. This comprehensive heading is adopted to include many aromatic stimulants, such as cardamoms, grains of paradise, &c., which are obtained from several plants related to amomum. German pharmacopolists even term Pimento berries, or Jamaica allspice, *semen amomi*; but this is never so called in Great Britain. Much obscurity hung over the history of the true cardamoms, which recent investigations have removed; and as Dr. Pereira has treated the whole subject at great length in his 'Materia Medica,' his statements are chiefly followed here.

The true, officinal, or Malabar cardamoms are procured from the *elettaria cardamomum* (Rheede, 'Hortus Malabaricus,' vol. ix.), White; the botanical characters of which were described by Dr. Maton ('Trans. Linn. Soc.' x. p. 254). The Edinburgh College term it *renealmia* (Rosc.); the London, *alpinia cardamomum* (Roxb.). It occurs in the mountainous parts of Malabar, and is also cultivated. The cardamoms of the Wynaad, which are the most esteemed and bring the highest price, are cultivated. The fruit is the part collected, but the seed alone is used. The seed-vessel or husk is altogether devoid of aroma or pungency; but the seeds should never be taken out of it till required for use, as they keep much better in their natural envelope: 100 parts of best cardamoms yield 74 parts of seed and 26 of husks. This kind of cardamoms, called the small or lesser, presents three varieties in commerce; namely, shorts, short-longs, and long-longs, placed in the order of their merit. The first and best are about three to six lines long; the second, about six; the last, from seven lines to an inch. Trommsdorf analysed the small cardamoms, and obtained—essential oil, 4·6; fixed oil, 10·4; a salt (probably malate) of potash, combined with colouring-matter, 2·5; fecula, 3·0; nitrogenous mucilage, with phosphate of lime, 1·8; yellow colouring-matter, 0·4; and woody fibre, 77·3.

The fixed oil somewhat resembles castor oil. The excellence of the specimen depends on the volatile oil; this is small in inferior kinds; the best yield about 6¼ drachms for every pound of the fruit. Jamaica cardamoms yield only four scruples for one pound of fruit. Like oil of turpentine, lemon, &c., it consists only of carbon and hydrogen.

Ceylon cardamoms, or larger, sometimes termed long, are produced in that island; but some of the less valuable of the Malabar fruits are termed Ceylon cardamoms. The name of "grains of paradise" is sometimes given to this plant. One kind of "grains of paradise" is from an African plant *Amomum Grana-Paradisi* (Smith); the other from *A. Meleguetta* (Roscoe), cultivated in Demerara. Grains of paradise are used to sharpen vinegar, beer, liquors, &c., and brewers who have them in their possession are liable to heavy penalties. [ADULTERATION.] The duty on grains of paradise was reduced from 2*s.* per lb. to 15*s.* per cwt. by 5 & 6 Vict. c. 47.

Cardamoms are in great favour in the East as a spice, and also as an aromatic stimulant in the treatment of disease. In Europe, they are as highly esteemed as carminative and stomachic agents. Dr. Christison observes that they form part of eighteen officinal preparations, besides their own tinctures.

AMORITES, the most powerful tribe of the Canaanites, or the aborigines of Palestine. The name Amorites seems sometimes to be used for all the Canaanites who were the descendants of Ham, through Canaan, Sidon, and Heth. (Gen. x. 15—20.) The Amorites are mentioned among the ten nations whose country was given to the seed of Abraham. (Gen xv. 19—21.) The original Amorites dwelt chiefly in the mountains, which afterwards belonged to the tribe of Judah. (Numbers xiii. 29; Deut. i. 20.) The name has been said by Simonsis and Gesenius to mean 'mountaineer.' Some Amorites dwelt in the plains bordering upon the tribe of Dan, and others between the rivers Jordan and Arnon. At the time of Moses the river Arnon was the border between Moab and the Amorites on the south, the Jordan on the west, and the Jabbok on the north, separated them from the kingdom of Bashan, and the Great Desert and the territory of the Ammonites formed their eastern boundary. (Numbers xxi. 13.) Of the cities of the Amorites it was said to the people of Israel, "Thou shalt save alive nothing that breatheth: but thou shalt utterly destroy the Hittites, Amorites, Canaanites, Perizzites, Hivites, and Jebusites, as the Lord thy God hath commanded thee, that they teach you not to do after all their abominations, which they have done unto their gods." (Deut. xx. 16-18.) The Amorites were attacked by the four confederate kings who took Lot captive (Gen. xiv. 13; Joshua x. 11), slew great numbers of them, and more died stricken with hailstones from heaven. But after all this, the Amorites retained so much power, that they forced (B.C. 1425) the children of Dan into the mountain, for they would not suffer them to come down to the valley. The remarkable fact, that the Israelites conquered the mountains sooner than the plains is explained (Judges i. 19): it was because the inhabitants of the plains had chariots of iron.

The Gibeonites (to whom seven descendants of Saul were delivered by David about the year B.C. 1020, that they might revenge themselves for Saul's atrocities) were of the remnant of the Amorites whom Joshua had made hewers of wood and drawers of water. (Joshua ix; 2 Samuel xx.) Moses and the children of Israel slew two kings of the Amorites, namely Sihon, who dwelt at Heshbon, and Og, king of Bashan, in the plain east of Jordan. These kings had refused to let the Israelites pass through their borders. (Judges xi. 18-23.) Still the Amorites were not extirpated, and their descendants formed, even during the time of the Maccabees, a distinct tribe; for we read in Josephus ('Antiquit.' xiii. chap. 1.) that the Amorites from Medaba fell suddenly upon the corps of Johannes Gaddis, when he was conveying the baggage of the Jewish host, according to the command of his brother Jonathan, and killed him.

The Amorites were of tall stature. According to Amos (ii. 9) they were high as cedars and strong as oaks. This poetical description is illustrated by the historical statement, that the size of the iron bedstead of the Amoritish king, Og of Bashan, was nine cubits by four. (Deut. iii. 11.) The rabbins have some wild legends respecting him; but it may be concluded that in ancient times the natives of Syria exceeded in stature the inhabitants of the desert and of Egypt.

AMPELIC ACID. ($C_{14}H_6O_6$). Obtained by the action of nitric acid upon the oily products of the destructive distillation of bituminous shale and of coal. Picric acid and a flocculent matter are collaterally formed, but on evaporating the liquor the two latter substances are first deposited. On then neutralising with ammonia, evaporating to dryness, and extracting with alcohol, ampelate of ammonia is dissolved. From the aqueous solution of this salt, nitric acid precipitates ampelic acid in a flocculent condition.

Ampelic acid is a white inodorous solid, insoluble in cold and only very sparingly soluble in hot water. Boiling alcohol and ether dissolve it readily. It fuses at 500° F., and may be distilled without decomposition. It is isomeric with salicylic acid.

AMPELINE, a brownish-yellow liquid resembling creosote, found amongst the oily products of the destructive distillation of bituminous shale. It is soluble in water, does not solidify at —4° F., and cannot be distilled alone without decomposition.

AMPHI'CTYONS, members of a celebrated council in ancient Greece, called the Amphictyonic Council.

According to the popular story, this council was founded by Amphictyon, son of Deucalion, who lived, if he lived at all, many centuries before the Trojan war. It is supposed by a writer quoted by Pausanias, x. 8, to derive its name, with a slight alteration, from a word signifying 'settlers around a place.' Strabo, who professes to know nothing of its founder, says that Acrisius, the mythological king of Argos, fixed its constitution, and regulated its proceedings. Amidst the darkness which hangs over its origin, we discover with certainty, that it was one of the earliest institutions in Greece. No full or clear account has been given of it during any period of its existence by those who had the means of informing us. The fullest information is supplied by Æschines the orator; but before any attempt is made, by the help of some short notices from other writers, and of conjecture, to trace its earlier history, it may not be amiss to state what is certainly known of this council as it existed in his time.

According to Æschines, the Greek nations which had a right to be represented in the council were twelve, though he only names eleven, the Thessalians, Bœotians, Dorians, Ionians, Perrhæbians, Magnesians, Locrians, Œtæans, Phthiots, Malians, Phocians: the twelfth were probably the Delphians. Each nation was represented by certain sovereign states, of which it was supposed to be the parent: thus Sparta, conjointly with other Dorian states, represented the Dorian nation. Amongst the states thus united in representing their common nation, there was a perfect equality. Sparta enjoyed no superiority over Dorium and Cytinium, two inconsiderable towns in Doris, and the deputies of Athens, one of the representatives of the Ionian nation, sat in the council on equal terms with those of Eretria in Eubœa, and of Priene, an Ionian colony in Asia Minor. From a rather doubtful passage in Æschines, 'De Fals. Leg.' 43, compared with a statement in Diodorus, xvi. 60, it seems that each nation, whatever might be the number of its constituent states, had two, and only two votes. The council had two regular sessions in each year, meeting in the spring at Delphi, and in the autumn near Pylæ, otherwise called Thermopylæ; but special meetings were sometimes called before the usual time. From its meeting at Pylæ, a session of the Amphictyons was called a Pylæa, and the deputies were called Pylagoræ, that is, councillors at Pylæ. There were also deputies distinguished by the name of Hieromnemons, whose office it was, as their name implies, to attend to matters pertaining to religion. Athens sent three Pylagoræ and one Hieromnemon. The former were appointed for each session; the latter probably for a longer period, perhaps for the year, or two sessions. The council entertained charges laid before it in relation to offences committed against the Delphic god, made decrees thereupon, and appointed persons to execute them. These decrees, as we learn from Diodorus, xvi. 24, were registered at Delphi. The oath taken by the deputies bound the Amphictyons not to destroy any of the Amphictyonic cities, or to debar them from the use of their fountains in peace or war; to make war on any who should transgress in these particulars, and to destroy their cities; to punish with hand, foot, voice, and with all their might, any who should plunder the property of the god (the Delphic Apollo), or should be privy to, or devise anything against that which was in his temple. This is the oldest form of the Amphictyonic oath which has been recorded, and is expressly called by Æschines the ancient oath of the Amphictyons. It has inadvertently been attributed to Solon by Mr. Mitford, who has apparently confounded it with another oath imposed on a particular occasion. An ordinary council consisted only of the deputed Pylagoræ and Hieromnemons; but on some occasions at Delphi, all who were present with the Amphictyonic deputies to sacrifice in the temple and consult the oracle of the god, were summoned to attend, and then it received the name of an *ecclesia* or assembly. Beside the list of Amphictyonic nations given by Æschines, we have one from Pausanias which differs a little from that of Æschines, and another from Harpocration which differs slightly from both. Strabo agrees with the orator as to the number being twelve. It is further remarkable, that whilst Æschines places the Thessalians at the head of his list, Demosthenes, 'De Pac.' p. 62, expressly excludes them from a seat in the council.

Æschines has left us much in the dark as to the usual mode of proceeding in the Amphictyonic sessions; and we shall look elsewhere in vain for certain information. It should seem that all the Pylagoræ sat in the council and took part in its deliberations; but if the common opinion mentioned above, respecting the two votes allowed to each nation, be correct, it is certain that they did not all vote. The regulations according to which the decisions of the twelve nations were made can only be conjectured. We know that the religious matters which fell under the jurisdiction of the Amphictyonic body were managed principally, at least, by the Hieromnemons, who appear, from a verse in Aristophanes, 'Nub.' 613, to have been appointed by lot, but we are not as well informed respecting the limits which separated their duties from those of the Pylagoræ, nor respecting the relative rank which they held in the council. (See Æsch. 'Contr. Ctes.' p. 68—72; 'Fals. Leg.' p. 43.) The little that is told is to be found for the most part in the ancient lexicographers and scholiasts, or commentators, who knew perhaps nothing about the matter, and whose accounts are sufficiently perplexing to give room for great variety of opinions among modern writers. Some have seemed to themselves to discover that the office of the Hieromnemons was of comparatively late creation, that these new deputies were of higher rank than the Pylagoræ, and that one of them always presided in the council; others again have supposed, what, indeed, an ancient lexicographer has expressly asserted, that they acted as secretaries or scribes. Two Amphictyonic decrees are found at length in the oration of Demosthenes on the Crown, both of which begin thus: "When Cleinagoras was priest, at the vernal Pylæa, it was resolved by the Pylagoræ and the Synedri (joint councillors) of the Amphictyons, and the common body of the Amphictyons." Some have assumed that Cleinagoras the priest was the presiding Hieromnemon, and others that the Hieromnemons are comprehended under the general name of Pylagoræ. Æschines again has mentioned a decree in which the Hieromnemons were ordered to repair at an appointed time to a session at Pylæ, carrying with them the copy of a certain decree lately made by the council. Of the council, as it existed before the time of Æschines, a few notices are to be found in the ancient historians, some of which are not unimportant. According to Herodotus, vii. 200, the council held its meetings near Thermopylæ, in a plain which surrounded the village of Anthela, and in which was a temple dedicated to the Amphictyonic Ceres; to whom, as Strabo tells us, ix. 429, the Amphictyons sacrificed at every session. This temple, according to Callimachus, 'Ep.' 41, was founded by Acrisius; and hence arose, as Müller supposes in his history of the Dorians (vol. i. p. 289, English translation), the tradition mentioned above.

We are told by Strabo, ix. 418, that after the destruction of Crissa by an Amphictyonic army, under the command of Eurylochus, a Thessalian prince, the Amphictyons instituted the celebrated games, which from that time were called the Pythian, in addition to the simple musical contests already established by the Delphians. Pausanias also, x. 7., attributes to the Amphictyons, both the institution and subsequent regulation of the games; and it is supposed by the most skilful critics, that one occasion of the exercise of this authority, recorded by Pausanias, can be identified with the victory of Eurylochus, mentioned by Strabo. According to this supposition, the Crissæan, and the celebrated Cirrhæan war, are the same, and Eurylochus must have lived as late as B.C. 591. But the history of these matters is full of difficulty, partly occasioned by the frequent confusion of the names of Crissa and Cirrha.

From the scanty materials left us by the ancient records, the following sketch of the history of this famous council is offered to the reader, as resting on some degree of probability :—

The council was originally formed by a confederacy of Greek nations or tribes, which inhabited a part of the country afterwards called Thessaly. In the lists which have come down to us of the constituent tribes, the names belong for the most part to those hordes of primitive Greeks which are first heard of, and some of which continued to dwell north of the Malian bay. The bond of union was the common worship of Ceres, near whose temple at Anthela its meetings were held. With the worship of the goddess was afterwards joined that of the Delphic Apollo; and thenceforth the council met alternately at Delphi and Pylæ. Its original seat and old connections were kept in remembrance by the continued use of the term Pylæa, to designate its sessions wherever held; though eventually the Delphic god enjoyed more than an equal share of consideration in the confederacy. It may be remarked that the Pythian Apollo, whose worship in its progress southwards can be faintly traced from the confines of Macedonia, was the peculiar god of the Dorians who were of the Hellenic race; whilst the worship of Ceres was probably of Pelasgic origin, and appears at one time to have been placed in opposition to that of Apollo, and in great measure to have retired before it. There is no direct authority for asserting that the joint worship was not coeval with the establishment of the council; but it seems probable from facts, which it is not necessary to examine here, that an Amphictyonic confederacy existed among the older residents, the worshippers of Ceres, in the neighbourhood of the Malian bay, before the hostile intruders with their rival deity were joined with them in a friendly coalition. The council met for religious purposes, the main object being to protect the temples and maintain the worship of the two deities. With religion were joined, according to the customs of the times, political objects; and the jurisdiction of the Amphictyons extended to matters which concerned the safety and internal peace of the confederacy. Hence the Amphictyonic laws, the provisions of which may be partly understood from the terms of the Amphictyonic oath. Confederacies and councils, similar to those of the Amphictyons, were common among the ancient Greeks. Such were those which united in federal republics the Greek colonists of Asia Minor, of the Æolian, Ionian, and Dorian nations. Such also was the confederacy of seven states whose council met in the temple of Neptune, in the island of Calauria, and which is even called by Strabo, viii. 374, an Amphictyonic council.

The greater celebrity of the northern Amphictyons is attributable partly to the superior fame and authority of the Delphic Apollo; still more, perhaps, to their connection with powerful states which grew into importance at a comparatively late period. The migrating hordes, sent forth from the tribes of which originally or in very early times the confederacy was composed, carried with them their Amphictyonic rights, and thus at every remove lengthened the arms of the council. The great Dorian migration especially planted Amphictyonic cities in the remotest parts of Southern Greece. But this diffusion, whilst it extended its fame, was eventually fatal to its political authority. The early members, nearly equal perhaps in rank and power, whilst they remained in the neighbourhood of Mounts Œta and Parnassus, might be willing to submit their differences to the judgment of the Amphictyonic body. But the case was altered when Athens and Sparta became the leading powers in Greece. Sparta, for instance, would not readily pay obedience to the decrees of a distant council, in which the deputies of some inconsiderable towns in Doris sat on equal terms with their own. Accordingly in a most important period of Grecian history, during a long series of bloody contests between Amphictyonic states, we are unable to discover a single mark of the council's interference. On the other hand, we have from Thucydides i. 112, a strong negative proof of the insignificance into which its authority had fallen. The Phocians (B.C. 448) possessed themselves by force of the temple of Apollo at Delphi; were deprived of it by the Lacedæmonians, by whom it was restored to the Delphians; and were again replaced by the Athenians. In this, which is expressly called by the historian a sacred war, not even an allusion is made to the existence of an Amphictyonic council. After the decay of its political power there still remained its religious jurisdiction; but it is not easy to determine its limits, or the objects to which it was directed. In a treaty of peace made (B.C. 421) between the Peloponnesians and the Athenians (Thucyd. v. 17), it was provided that the temple of Apollo at Delphi, and the Delphians, should be independent. This provision, however, appears to have had reference especially to the claims of the Phocians to include Delphi in the number of their towns, and not to have interfered in any respect with the superintendence of the temple and oracle, which the Amphictyons had long exercised in conjunction with the Delphians. We have seen that the Amphictyons were charged in the earliest times with the duty of protecting the temple and the worship of the god. But the right of superintendence, of regulating the mode of proceeding in consulting the oracle, in making the sacrifices, and in the celebration of the games, was apparently of much later origin, and may, with some probability, be dated from the victory gained by Eurylochus and the Amphictyonic army. The exercise of this right had the effect of preserving to the council permanently a considerable degree of importance. In early times the Delphic god had enjoyed immense authority. He sent out colonies, founded cities, and originated weighty measures of various kinds. Before the times of which we have lately been speaking, his influence had been somewhat diminished; but the oracle was still most anxiously consulted both on public and private matters. The custody of the temple was also an object of jealous interest on account of the vast treasures contained within its walls.

The Greek writers, who notice the religious jurisdiction of the council, point our attention almost exclusively to Delphi; but it may be inferred from a remarkable fact mentioned by Tacitus, 'Ann.' iv. 14, that it was much more extensive. The Samians, when petitioning in the time of the Emperor Tiberius for the confirmation of a certain privilege to their temple of Juno, pleaded an ancient decree of the Amphictyons in their favour. The words of the historian seem to imply that the decree was made at an early period in the existence of Greek colonies in Asia Minor, and he says that the decision of the Amphictyons on all matters had at that time pre-eminent authority.

The sacred wars, as they were called, which were originated by the Amphictyons in the exercise of their judicial authority, can here be noticed only so far as they help to illustrate the immediate subject of inquiry. The Cirrhæan war, in the time of Solon, has already been incidentally mentioned. The port of Cirrha, a town on the Crissæan bay, afforded the readiest access from the coast to Delphi. The Cirrhæans, availing themselves of their situation, grievously oppressed by heavy exactions the numerous pilgrims to the Delphic temple. The Amphictyons, by direction of the oracle, proclaimed a sacred war to avenge the cause of the god; that is, to correct an abuse which was generally offensive, and particularly injurious to the interests of the Delphians. Cirrha was destroyed, the inhabitants reduced to slavery, their lands consecrated to Apollo, and a curse was pronounced on all who should hereafter cultivate them. We are told that Solon acted a prominent part on this occasion, and that great deference was shown to his counsels. Mr. Mitford, indeed, has discovered without help from history, which is altogether silent on the subject, that he was the author of sundry important innovations, and that he in fact remodelled the constitution of the Amphictyonic body. He has even been able to catch a view of the secret intentions of the legislator, and of the political principles which guided him. But in further assigning to Solon the command of the Amphictyonic army, he is opposed to the direct testimony of the ancient historians.

From the conclusion of the Cirrhæan war to the time of Philip of

Macedon, an interval exceeding two centuries, we hear little more of the Amphictyons, than that they rebuilt the temple at Delphi, which had been destroyed by fire B.C. 548; that they set a price on the head of Ephialtes, who betrayed the cause of the Greeks at Thermopylæ, and conferred public honours on the patriots who died there; and that they erected a monument to the famous diver Scyllias, as a reward for the information which, as the story goes, he conveyed under water from the Thessalian coast to the commanders of the Grecian fleet at Artemisium. If Plutarch may be trusted, the power of the Amphictyons had not at this time fallen into contempt. When a proposition was made by the Lacedæmonians to expel from the council all the states which had not taken part in the war against the Persians, it was resisted successfully by Themistocles, on the ground that the exclusion of three considerable states, Argos, Thebes, and the Thessalians, would give to the more powerful of the remaining members a preponderating influence in the council dangerous to the rest of Greece.

After having, for a long period, nearly lost sight of the Amphictyons in history, we find them venturing, in the fallen fortunes of Sparta, to impose a heavy fine on that state as a punishment for an old offence, the seizure of the Theban Cadmeia, the payment of which, however, they made no attempt to enforce. In this case, as well as in the celebrated Phocian war, the Amphictyonic council can be considered only as an instrument in the hands of the Thebans, who after their successful resistance to Sparta, appear to have acquired a preponderating influence in it, and who found it convenient to use its name and authority, whilst prosecuting their own schemes of vengeance or ambition. Though the charge brought against the Phocians was that of impiety in cultivating a part of the accursed Cirrhæan plain, there is no reason to think that any religious feeling was excited, at least in the earlier part of the contest; and Amphictyonic states were eagerly engaged as combatants on both sides. For an account of this war, the reader is referred to a general history of Greece. The council was so far affected by the result, that it was compelled to receive a new member, and in fact a master, in the person of Philip of Macedon, who was thus rewarded for his important services at the expense of the Phocians, who were expelled from the confederacy. They were, however, at a subsequent period restored, in consequence of their noble exertions in the cause of Greece and the Delphic god against the Gauls. It may be remarked, that the testimony of the Phocian general Philomelus, whatever may be its value, is rather in favour of the supposition that the council was not always connected with Delphi. He justifies his opposition to its decrees, on the ground that the right which the Amphictyons claimed was comparatively a modern usurpation. In the case of the Amphissians, whose crime was similar to that of the Phocians, the name of the Amphictyons was again readily employed; but Æschines, who seems to have been the principal instigator of the war, had doubtless a higher object in view than that of punishing the Amphissians for impiety.

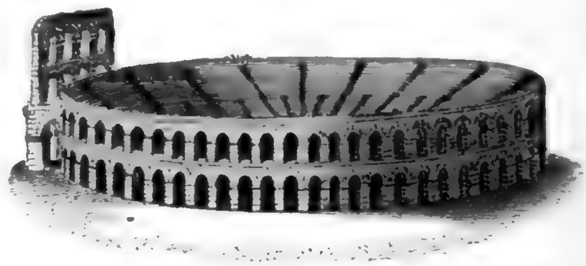
The Amphictyonic council long survived the independence of Greece, and was, probably, in the constant exercise of its religious functions. So late as the battle of Actium, it retained enough of its former dignity at least, to induce Augustus to claim a place in it for his new city of Nicopolis. Strabo says that in his time it had ceased to exist. If his words are to be understood literally, it must have been revived; for we know from Pausanias (x. 8.), that it was in existence in the second century after Christ. It reckoned at that time twelve constituent states, who furnished in all thirty deputies; but a preponderance was given to the new town of Nicopolis, which sent six deputies to each meeting. Delphi sent two to each meeting, and Athens, one deputy; the other states sent their deputies according to a certain cycle, and not to every meeting. For the time of its final dissolution, we have no authority on which we can rely.

It is not easy to estimate with much certainty the effects produced on the Greek nation generally, by the institution of this council. It is, however, something more than conjecture, that the country which was the seat of the original members of the Amphictyonic confederacy, was also the cradle of the Greek nation, such as it is known to us in the historical ages. This country was subject to incursions from barbarous tribes, especially on its western frontier, probably of a very different character from the occupants of whom we have been speaking. In the pressure of these incursions, the Amphictyonic confederacy may have been a powerful instrument of preservation, and must have tended to maintain at least the separation of its members from their foreign neighbours, and so to preserve the peculiar character of that gifted people, from which knowledge and civilisation have flowed over the whole western world. It may also have aided the cause of humanity; for it is reasonable to suppose that in earlier times, differences between its own members were occasionally composed by interference of the council; and thus it may have been a partial check on the butchery of war, and may at least have diminished the miseries resulting from the cruel lust of military renown. In one respect, its influence was greatly and permanently beneficial. In common with the great public festivals, it helped to give a national unity to numerous independent states, of which the Greek nation was composed. But it had a merit which did not belong to those festivals in an equal degree. It cannot be doubted that the Amphictyonic laws, which regulated the originally small confederacy, were the foundation of that international law which was recognised throughout Greece; and which, imperfect as it was, had some effect in regulating beneficially national intercourse among the Greeks in peace and war, and, so far as it went, was opposed to that brute force and lawless aggression, which no Greek felt himself restrained by any law from exercising towards those who were not of the Greek name. To the investigator of that dark but interesting period in the existence of the Greek nation, which precedes its authentic records, the hints which have been left us on the earlier days of this council, faint and scanty as they are, have still their value. They contribute something to those fragments of evidence with which the learning and still more the ingenuity of the present generation are converting mythical legends into a body of ancient history.

AMPHIPROSTYLE. This is an architectural term, compounded of three Greek words. It is used to designate structures having the form of an ancient Greek or Roman parallelogramic temple, with a prostyle or portico on each of its ends or fronts, but with no columns on its sides or flanks. [TEMPLE.]

AMPHI'SCII, literally *double shadowed*, a Greek term applied by ancient astronomers to the inhabitants of the torrid zone, with whom the sun passes the meridian at noon, sometimes on the north, sometimes on the south, of the zenith, and whose shadows at noon are therefore turned to the south during one part of the year, and to the north during the remainder.

AMPHITHE'ATRE, the name by which a species of structure much used by the Romans, and combining the forms and some of the uses



Amphitheatre of Verona.

of the ancient theatre and circus, is generally distinguished; indeed most of the Roman classical writers apply to it the name of circus also. A distinction, however, is now always made; the term amphitheatre being applied to the species of structure here referred to, and circus being restricted to the Roman stadium or hippodrome. [CIRCUS.]

The name amphitheatre seems intended to convey the idea of a double theatre; but what is termed a theatre is, with reference to its original uses, more strictly an odeum, and what we call an amphitheatre was truly a theatre. The one was for hearing music and recitations, and the other for seeing sights,—as the words import. [THEATRE.]

The form of the amphitheatre is, on the plan, that of an ellipsis, with a series of arcaded concentric walls, separating corridors which have constructions with staircases and radiating passages between them. It encloses an open space called the arena, either on, or a very little above or below the level of the surface of the ground on which the structure is raised. From the innermost concentric wall,—which bounds the arena, and which will be from ten to fifteen feet above its level,—an inclined plane runs upwards and outwards over the intermediate wall, staircases, and corridors, to a gallery or galleries over the outermost corridors. The inner and upper part of the inclined plane is covered with a graduated series of benches following the general form of the plan; these are intercepted at intervals by radial passages leading by a more easy gradation to and from the staircases which pass through the substructions of the benches to the corridors. These corridors, in the principal stories, continue uninterruptedly all round the edifice, and afford easy access to, and egress from, every part. In cases where the radiating passages through the bank of benches were few, concentric platforms or precinctions went round to make the communications complete. The external elevation of an amphitheatre is almost dictated by its internal arrangement and construction, and it generally falls into two or more stories of open arches, which are necessary to give light and air to the corridors and staircases.

The Amphitheatre seems to have been contrived for the more convenient exhibition of such shows as were confined throughout to the same place, such as combats, which could not be seen advantageously along the length of the circus; and moreover the circus had not the lofty stereobate, podium, or cincture, to protect the spectators from the savage and powerful brute animals which were frequently used in the public shows of the Romans. Indeed, it is reported that this defect was a cause of the abandonment of the circus for such exhibitions as required the use of wild beasts. The great length also of the circus would be a sufficient reason for adopting the more compressed and lofty form given to the amphitheatre, whose arrangement admits of a far greater number of persons being brought within a smaller area, and consequently within more convenient view of the arena.

At first, and for some time, amphitheatres were constructed of timber. Several accidents occurred, indeed, in consequence of the use of such, from fire, and from their incapacity to bear the weights they were subjected to; and, in one instance, it is related (Tacitus, 'Annal.' iv. 62; Suetonius, 'Tiber.' 40), that an amphitheatre of this kind fell during the exhibition of the shows, in the town of Fidena, when a very large number of persons, variously stated at 20,000 and 50,000, were either killed or hurt. Afterwards they were more securely and more permanently constructed of brick or stone, according to the facilities the place afforded, or the means of the people at whose expense the structures were raised.

It was in the latest period of the Republic that the Romans were debased by the gladiatorial and other shows which led to the use and construction of amphitheatres; and to the gratification of this passion for demoralising public spectacles may be attributed, in some degree, its eventual overthrow, in all but form, and the establishment of the despotism of the emperors. All the powerful men in the state who aimed still higher, sought favour with the people by these barbarous entertainments; and the sums expended and the numbers of men and beasts engaged, and for the most part destroyed, in furnishing them seem almost incredible.

The difference in the national characteristics of the Greeks and Romans is by nothing more forcibly illustrated than by the constant indications of theatres or odeums which mark the sites or immediate vicinities of ancient Greek cities, and the remains of amphitheatres which are common to those of the Romans.

To save unnecessary expense, the Grecian theatre was formed on or in the side of a hill, whenever the locality would afford this advantage; the seats were generally cut in the living rock, and such constructions added before it in the formation of the orchestra and proscenium and their accessories, as were absolutely necessary to complete the theatre. The amphitheatre of the Romans was raised, for the most part, within the town or city, on the level plain, of costly magnificence, and generally of enormous extent, while their theatres are in every respect secondary, and of inferior importance. Indeed, theatres for music and the drama are seldom found among the remains of purely Roman cities, but almost every Roman colony, and even camp, bears indications of a constructed or excavated amphitheatre. The great mother city of Rome herself can hardly be said to exhibit the remains of a theatre, unless it be that which is called the theatre of Marcellus; and even this appears to have been more used for games of the circus, or amphitheatrical shows, than for dramatic representations, and is not of extraordinary extent. But the Colosseum would contain from eighty to a hundred thousand persons;—and the little city of Pompeii, which has indeed two theatres, has, moreover, an amphitheatre, whose arena alone would contain them both. The Grecian cities of Sicily, on the contrary, exhibit remains and indications of spacious theatres where those of the amphitheatres of their Roman masters are few and unimportant; and the old cities of Greece itself, and the Grecian cities of Asia Minor, are almost entirely free from the pollution of the amphitheatre,—the Roman garrisons appearing to have contented themselves with castrensian or camp-built amphitheatres alone. Of this sort,—the castrensian amphitheatre,—we have indications still existing in England;—the principal are at Banbury, Cirencester, Dorchester, Richborough, Silchester, and Caerleon; but these were originally little more than mere excavations, or turf-built cinctures made up with what walling was absolutely necessary to form the grand concentric bank of benches. In the provinces of Gaul,—both transalpine and cisalpine,—Nîmes and Verona, by the remains of their amphitheatres, show how much more completely the inhabitants were nationalised, or Romanised, than were those of Greece or of Britain.

There is, perhaps, no species of structure peculiar to the Romans, with the details of which we are so well informed, as of those of the amphitheatre, and there is hardly any one of which we have fewer descriptions by ancient writers. The remains which still exist in various places tell us much more plainly what they were than the most elaborate descriptions can do; and although there is no example of an amphitheatre in complete preservation, or even nearly so, yet the existing specimens preserve the various parts so completely, that there is but little difficulty in supplying from one of them what is defective in another. Still there are minor particulars of which we must remain ignorant, unless we take them from such descriptions as exist, or supply them from analogy. We know of no sort of ancient edifice, generally, in which so much ingenuity is displayed in the arrangement, or so much skill in the construction, as were exemplified by the Romans in the design and execution of the amphitheatre; but for architectural character, the external composition of the amphitheatre is very far from being entitled to praise.

As the most remarkable, and one of the most perfect in its details, of the remaining examples of the amphitheatre, that which is known as the Colosseum at Rome is here used to illustrate this kind of edifice; the plan and elevation are almost entirely made out from the existing remains; and the section also, to a certain extent, as well as from the analogy afforded by other examples and from probability. The vignette sketch at the head of this article is a view of the amphitheatre of Verona, as it exists, looking down into it; this will aid the section in giving an idea of the arrangement of the benches, and the mode of access to them.

The form of the external periphery of the plan is that of an ellipsis, whose conjugate diameter, or minor axis, is to the transverse, or major axis, as five to six, nearly,—the length through, from outside to outside of the external wall, being 620 feet, and the breadth to the same extent, 513 feet; but as these dimensions are variously stated by different authorities, something may be allowed for inaccuracy, and the proportion between one diameter and the other may be fairly assumed in the original draft to have been as above stated. Of course, in the diminishing series of concentric walls, the proportion of the ellipsis is continually altering, so that the diameters of the arena are as five to eight, as nearly as may be, the length being 287 feet, and the breadth 180 feet. The difference between the external and internal diameters, of 333 feet, or 166 ft. 6 in. at each end, is occupied by four corridors and two blocks of radiating substructions,—in, or between, which are the staircases and ways from the outer corridors to the inner, and to the arena, together with the concentric or encircling walls which gird the structure, separate the corridors, and enclose the arena. Two of the surrounding corridors lie together, or adjoin each other, on the outer side; and in this particular the Colosseum exceeds every other structure of the kind of which we have any knowledge, all the rest having but one only; it thus acquires a second gallery, as may be perceived by referring to the section, in which, also, it is singular. The space covered by this immense edifice will be found to be little short of six acres. Seats were provided for 80,000 spectators; while the arena was sufficiently capacious to admit of several hundred animals fighting within it at one time, or the evolutions of numerous vessels in mimic sea-fights, and several other exhibitions requiring great amplitude of space.

The outer encircling wall is pierced with eighty openings, leaving, of course, an equal number of piers; every opening is arched, and in or against every pier is a column projecting about half its diameter, and supporting an entablature which runs in an unbroken line all round the structure. With the exception of the four central openings, which lie on the diameters of the ellipsis, and are each nearly two feet wider than the rest, all the openings are very nearly the same, their width being 14 feet 6 inches. An exactly similar series of arches, diminished only in proportion to the smaller extent of the ellipsis, separates the second corridor from the first; and another, bearing the same relation to the second series, that the second does to the first, or outer, bounds the second corridor. The inner faces of the outer piers, both faces of the piers of the intermediate series, and the outer faces of the piers of the innermost series, have pilasters projecting from them, corresponding in height with the external columnar ordinance, and bearing a moulded architrave from the top of which semicircular arches are turned over the corridors and continued all round the edifice. The accompanying plan and section exhibit the general arrangement of the corridors here described, though the details cannot, on so small a scale, be made obvious. The elevation shows how a second and third columnar ordinance, with corresponding and nearly similar arched intervals, superimpose the lowest, and each other, and that each of these two upper ordinances rests upon a continued stylobate or dado, which is broken into every interval or under every column. The section indicates the repetition of the double series of outer corridors in every story, or behind every one of the three columnar ordinances, and above the outermost corridor in the third story, a mezzanine, or small middle story, for a corridor behind the first, and under the second, or upper, gallery. The same diagrams show that the third story of columns is superimposed by a pilastrated ordinance on a continued and recessed dado also, with a deep plinth; they show, moreover, that a bold and massive entablature crowns the whole elevation, and runs its cornice round in one unbroken line.

From the third series of eighty piers, on the ground story, as many walls, with the exceptions to be noticed, run inwards to the third concentric corridor, which is arched over as the outer ones are; the walls are continued on the other side of it to the fourth or innermost corridor, which is bounded on the other side by the massive wall of the podium encircling the arena, and is also arched over, though it is not so lofty as the other three corridors are. Between the radiating walls of the two blocks separating the second from the third, and the third from the fourth corridors, are of course as many intervals. Some of these form the traversing passages; and the rest, in the outer block, contain the staircases which lead to the upper concentric corridors, and so onward to the upper benches and galleries; in the inner block are those which lead to the lower benches, and small staircases in the thickness of the innermost wall conduct to the benches immediately on the podium. The benches extend in one long graduated and concentric series from the podium up to the level of the second story of the outer corridors, and over all the constructions within the second of them. They are bounded above by a wall which is pierced with doors; these give access from the upper and inner corridor to the radiating flights of steps which intercept the benches at intervals, and cut them up into wedges, by which name in Latin, *cunei*, the divisions thus made were distinguished. This encircling wall has windows in it also, which may have been requisite to aid in ventilating the immense area; or they may have been intended merely to afford a view of the arena to persons who

Ground Plan of an Amphitheatre—The Colosseum.

could not find room on the benches. The section shows that the radiating flights of steps intercepting the benches do not run through their whole extent, but are themselves intercepted and taken up again, other lines or flights commencing intermediately and at intermediate heights. Access is given to these flights at their upper ends by doorways from the corridors behind, sometimes directly, and sometimes by means of the internal staircases; and in most cases a short reversed flight of steps is made on the outside of the doorways, or vomitories, as they are termed, to afford headway, and avoid intercepting the benches further back than could be possibly helped. Almost every thing that appears in the section above the level of the third story, except the external wall itself, is restored from analogy and conjecture. The peristyle, or encircling range of columns before the upper gallery, is entirely from conjecture; but for the galleries themselves there is sufficient evidence in the existing indications of stairs, and in the toothings of the remaining walls and piers. The benches in the grand series were probably of stone, perhaps of marble; but in the galleries it is most likely they were of wood, and graduated so as to give their occupiers a view of the arena.

The most distinguished seats were those on the podium, and these were assigned to the emperor, whose place was, by way of eminence, called the *suggestum*, and to the senators, to foreign ambassadors, and to the great officers of the state. The magistrates appear to have sat here in their curule chairs: and the person who gave the games seems to have occupied a sort of pulpit on the podium, called the *editoris tribunal*. The *cunei*, or wedges, behind and above, were assigned to different classes, according to their rank, station, and tribe. The Vestal virgins had one of the best positions assigned to them, and with them sat such ladies of high rank as could obtain the advantage; but the women generally occupied the open gallery at the top.

As the plan indicates, the four central entrances—those which lie on the ends of the diameters of the ellipsis—are wider than the corresponding parts of the rest of the structure. They were arcaded through, and finished more carefully, especially those leading from the sides, or on the minor axis; these, it is most likely, were reserved for those persons who went to the seats on the podium, and as they gave access also to the arena, they would of necessity be more strictly guarded.

It does not appear that any part of the structure above the level of the ground, and outside of the arena, was appropriated as dens for the beasts which were used in the shows; for indeed the corridor leading to the principal seats in the amphitheatre must have been traversed by them in their way to the arena, if that were the case. Substructions were discovered and excavated a few years ago over the whole extent of the arena; these lead to a belief that it was floored with wood, so that the animals required for the day may have been kept in dens under the floor, and allowed to issue at traps in it. But some have supposed dens ranged all round the arena, within its surface and below the podium, from which the beasts would issue to the combat directly.

In the Colosseum the great crowning cornice of the external elevation is pierced through at regular intervals with square holes or mortises, from which grooves are cut down through the rest of the entablature flush with the outer surface of the wall; and every mortise and groove is immediately above a strong projecting stone or corbel at about two-thirds the height of the pilastraded ordinance. These are supposed to have been used to insert and receive poles to carry an awning strained over the whole inclosure to protect the spectators from the sun and from rain. It is however difficult to understand how such an extent of cloth or canvass could have been borne in that manner without some intermediate support, of which we are not aware.

The external elevation is composed,—as it has been already described, and as the elevation indicates,—of three series or stories of attached or engaged columns with their usual accessories, and a pilastraded ordinance, forming a species of attic, which is pierced with windows, —one in every other interspace. The lowest ordinance of columns rests on the upper step of the substructions, or on the ground floor of the structure; it is of what is termed the Doric style or order, but in the debased Roman manner, and its entablature wants the distinguishing feature of that style, the triglyph. The intervening arches are semicircular; they spring from moulded imposts, and have moulded archivolts on their outer faces. The second ordinance is in the Roman Ionic style, having voluted capitals to the columns; and the third is in the Corinthian or foliated style: these, as before stated, rest upon continued, but broken or recessed, stylobata, but their entablatures are, like the rest, perfectly unbroken throughout, and the arches in the intercolumniations in both, correspond exactly—except in minor details—with those of the lowest or Doric ordinance. The pilasters have foliated capitals also, and are called composite; they rest on deep plinths under which there is a continued and recessed dado superimposing the Corinthian entablature;—this dado is pierced with holes or small windows, alternating with those of the ordinance above, to give light to the corridor behind the lower and under the upper gallery on the inside. The crowning entablature is made bold and effective by deep modillion blocks or consoles occupying the whole depth of the frieze.

The style of these architectural decorations is, for the most part, rude and tasteless; the Colosseum, however, from its magnitude, from its general form, and no doubt also from the feelings arising from the contrast between its present state and ancient splendour, never fails to produce a profound impression on the spectator. Internally the amphitheatre must always have been strikingly grand and impressive; here none of the littlenesses of storied columns appeared, but the long unbroken lines of the podium, and the graduated series of the benches, and the galleries with the encircling peristyle above—when it existed —would have been as beautiful in general effect, as anything architecture ever produced.

There are varieties in the arrangement of the details of the amphitheatre, as other examples show. Intermediate concentric galleries, platforms, or precinctions sometimes intercepted the great bank of graduated benches to serve as passages of communication; and sometimes each staircase communicated directly and exclusively with one vomitory, instead of leading to encircling corridors which communicated generally, and gave access alike to every part of the enclosure.

Next in importance to the Colosseum at Rome, of existing structures of the kind, is the Ampitheatre of Verona. The prefixed vignette will give a tolerable idea of its state of preservation. The great external cincture is entirely gone, with the exception of four arches and their accessories; but the great bank of concentric benches, with the staircases leading to them, and the parts about the arena, remain in a comparatively perfect state. The outer cincture was pierced with seventy-two arches, which number appears in the inner, with the corresponding radiating walls to the traversing passages and staircases, —for this had not a second encircling corridor on the outside of the stairs block as the Colosseum has. The outer dimensions of this structure were 502 feet by 401 feet; the length of its arena is 242 feet, and its breadth or length, on the conjugate, 146 feet; the form, of course, was ellipitical.

The amphitheatre at Nîmes in Languedoc is large (430 feet by 378), and in comparatively good preservation. The great external cincture of an amphitheatre (436 feet by 346) remains in a very perfect state at Pola in Istria. Rome contains the remains of a second amphitheatre called the Castrensian. There are also considerable remains of an amphitheatre at Capua, rivalling in size that at Verona; and of another at Pozzuoli near Naples. That of Pompeii, it has been already remarked, was an extensive structure. It was also in many respects peculiar, but it is not so well preserved as some other examples which have been more exposed, as it suffered considerably from earthquakes before it was buried. At Pæstum, there are indications of an amphitheatre, though not a large one; at Catania, in Sicily, the upper and outer encircling corridor of an extensive amphitheatre is accessible, considerably under the level of the modern city, buried by the torrents of lava from Mount Etna. Syracuse and several other of the ancient cities of Sicily exhibit remains or indications of small amphitheatres. In our own country, as has been noticed, there are several vestiges of amphitheatres; indeed, wherever Roman remains are found to any extent, whether at home or abroad, some indication may be almost certainly discovered of the existence at some time of an amphitheatre.

AMPHITRI'TE, is represented by Hesiod as a goddess, the wife of Poseidon or Neptune, to whom she bore three sons; and she changed Scylla into a horrible monster when she had become jealous of her. By later poets she is treated as the goddess of ocean generally. There was a temple to Neptune and Amphitrite at Tenos, as is shown by an inscription on one of the marbles of the Elgin collection in the British Museum; and in the temple of Poseidon on the Corinthian Isthmus, there was a statue of the goddess. Amphitrite was represented in Greek art as resembling Aphrodite, but her hair was confined by a net. There is a colossal statue of her in the Villa Albani at Rome. She is also frequently represented on coins, especially on those of Syracuse.

AMPHITRITE. One of the group of small planets revolving between Mars and Jupiter. [ASTEROIDS.]

A'MPHORA (ἀμφορεύς), in its ordinary acceptation, means an earthen vessel, used as a measure for liquids both by the Greeks and Romans, and for preserving wine, grapes, olives, oil, and other articles which required careful keeping. It received its name on account of its two ears or handles. It is generally two feet, or two feet and a half in height: and the body, which is usually about six inches in diameter, ending upwards with a short neck, tapers toward the lower part almost to a point. This pointed end was inserted in a hole in the ground, or in a stand to keep the vessel upright. The Attic amphora contained three Roman urnæ, or seventy-two sextaries, equal to about two gallons five pints and a half of English wine-measure. The Roman, sometimes called the Italic amphora, contained two urnæ or forty-eight sextaries, about seven gallons one pint English. Homer mentions amphoræ both of gold and stone; in later times glass amphoræ were not uncommon; and the Egyptians had them of brass. There are various specimens of earthen amphoræ in the British Museum, in the Elgin and Townley Galleries.

There was another amphora among the Romans, which was a dry-measure, and contained about three bushels.

Earthen amphoræ of the Roman time have been frequently found in England. Like other domestic vessels of the Romans, they appear to have been sometimes used as funeral urns. They were also used as coffins: the amphora was cut in half in the direction of its length, and the corpse having been placed inside, the two halves were united again and buried. Amphoræ used for wine were usually lined with pitch or some other coating, on account of the porous nature of the material of which they were formed. Amphoræ were placed as urinals in the public streets of Rome till the time of Vespasian. The burden of ships was reckoned by amphoræ.

The amphora is still the largest liquid measure used by the Venetians, containing sixteen quarts.

AMPLITUDE, the angular distance of a celestial body from the east point when it rises, or from the west point when it sets. It depends upon the declination of the star and the latitude of the place, and may be computed from the formula,

$$\text{sin. amplitude} = \frac{\text{sin. declination}}{\text{cos. latitude.}}$$

It must be measured towards the north or south points of the horizon, according as the declination is north or south. For the fixed stars, the amplitude remains the same throughout the year: but for the sun it varies with the declination, being nothing at the equinoxes, and about $3\frac{1}{2}$ points of the compass at the solstices, or more exactly 39° 44′ of amplitude, in the latitude of London; that is, at the summer solstice, it rises between N.E. by E. and N.E., and sets between N.W. by W. and N.W.; and at the winter solstice, it rises between S.E. by E. and S.E., and sets between S.W. by W. and S.W.

The term amplitude was also applied to what is more commonly called the *range* of a gun; that is, the whole horizontal distance which the gun will carry. It is sometimes also used in the integral calculus.

AMPUTATION, from *amputo*, to cut off; the operation of cutting off a limb from the body. Such is the constitution of the animal body in general, and especially of the more perfectly organised body, that if one part of it be diseased, the whole system suffers, while a general disturbance of the system cannot exist long without producing specific disease in some individual organ. Hence constitutional and local diseases are found to exert a most important influence over each other. Some local diseases are of an incurable nature, and proceed progressively from bad to worse. At first, these diseases may not materially affect the general health, but in their progress they produce so much constitutional disturbance, as to endanger life, and ultimately to destroy it. In this case, life is really endangered and destroyed by the local malady; remove that, provided the removal can be effected before the general health is irreparably impaired, and not only is death averted, but health itself is restored. Hence, in all ages, the necessity and advantage have been obvious enough, of removing a part of the body for the sake of preserving the remainder, and men have always been willing to submit to the loss of a limb in order to save the body, on the ground "that it is better to live with three limbs than to die with four."

But although it must always have been clear, that it is a gain to save life even at the cost of a limb, when nothing but the removal of the limb can preserve the body, yet it was not always easy to make the sacrifice. Whoever understands the circulation of the blood, and considers the quantity that is sent, and that must necessarily be sent, to each member of the body for its nourishment, and the magnitude of the blood-vessels that are divided in cutting off a limb, will readily perceive how impossible it must have been to perform the operation of amputation before any certain mode was known of stopping the flow of blood from the wounded blood-vessels. But no such mode of stopping hæmorrhage was known to the ancients: consequently, though they daily saw the necessity of performing the operation of amputation, yet they looked upon the operation with terror, and shrunk from the responsibility of undertaking it. And no wonder: when they did venture upon it, the consequences were appalling. They cut through the flesh with a red-hot knife, hoping by this means to prevent a fatal loss of blood. After having performed this operation, they dressed the wound with scalding oil, in order to complete what the burning knife may have left imperfect. But these expedients stopped only for a short time the flow of blood. The whole surface of the wound was converted into an eschar, which for a time stopped the bleeding. But the eschar being dead matter it was at length thrown off by the action of the living parts beneath. The moment this took place, the mouths of the blood-vessels were again opened, hæmorrhage took place just as at first, and the patient perished from loss of blood. The uniformity with which this event took place after amputation performed in this mode, could not but cause the operation to be regarded with dismay. Nevertheless, it is pretty clear, that in the time of Celsus, the surgeons of that age were not without some notion of the true mode of stopping hæmorrhage from wounded blood-vessels, for that writer gives particular directions to take hold of the vessels, to tie them in two places, and then to divide the intermediate portion; certain, however, it is, that this practice was not extended to amputation, because nothing was ever amputated by the ancients but a part absolutely mortified or dead; and in a part thus mortified or dead, it is not practicable to secure the blood-vessels by the needle and ligature. The general introduction into surgery, of the method of stopping hæmorrhage by taking up the divided blood-vessel with a needle, and placing a ligature around it, must, therefore, be considered as much a modern improvement, as if no allusion whatever had been made to it by ancient writers.

But if a knowledge of the mode of stopping hæmorrhage by tying the blood-vessel, be indispensable to the safety of surgical operations in general, the knowledge of some mode of preventing the loss of blood during the actual performance of an operation is indispensable to the safety of the operation of amputation in particular. So large are the trunks of the main blood-vessels that supply the limbs, and so great is the quantity of blood that flows from them in a short space of time, that loss of life is always the consequence of a want of command over these great vessels. By the invention of the instrument termed the tourniquet, an invention of the 17th century [TOURNIQUET], this command is obtained. By these instruments, then, namely, the tourniquet, and the needle and ligature, modern surgeons have such a perfect command over the blood-vessels, that operations may be performed, in which the largest trunks are divided without the loss scarcely of a single drop of blood. On this account, the mere removal of a limb excites in the modern surgeon no degree of anxiety; the operation of amputation is scarcely ever attended with the slightest hazard; nevertheless, there are circumstances connected with amputation of the greatest possible importance, delicacy, and difficulty, on a clear and correct view of which life depends; to obtain such a view, the most extensive knowledge, and the most accurate discrimination, are requisite; while, to act in conformity with it, a high degree of moral courage is often no less necessary. Perhaps the determination of the exact time at which to amputate is sometimes among the most difficult points of surgery; that is, the determination of the time when the preservation of the limb is no longer possible; and when, therefore, it is right to put an immediate stop to any further exhaustion of the health and strength by the removal of the limb. The recent introduction of the use of anæsthetics, in order to produce a state of insensibility in those submitting to the operation of amputation, has been found to exercise a most beneficial effect on recoveries after amputation. [ANÆSTHETICS.]

AMULET, in barbarous Latin, *Amuletum*, or *Amoletum*. It comes from the Arabic *Hamalet*, a thing suspended. An amulet hung round the neck, or carried in any other way about the person, is absurdly believed to have the effect of warding off morbid infections and other dangers, and even of curing diseases by which the body has been already attacked. The belief in the efficacy of amulets has subsisted at some time among almost every people, and the thing has been denoted by a great variety of names, which it is unnecessary here to enumerate. The phylacteries, or bits of parchment with passages from the Bible written upon them, which the Jews were wont to carry about with them, were amulets; such were probably the ear-rings mentioned in Genesis xxxv. 4; and in Hosea ii. 13. Jerusalem is represented as decking herself with the ear-rings of Baalim. Of the same character as the Jewish phylacteries are the scraps of paper inscribed with sentences from the Koran, which the Moorish priests sell to the negroes of Africa, and to which the latter give the name of *Fetishes*. This superstition, which existed also among the Greeks and Romans, appears to have in early times prevailed extensively among the converts to Christianity, if we may judge by the denunciations directed against it by St. Chrysostom, and others of the fathers. But even down to our own day, it has continued to be an article of the popular creed, that certain medical preparations, and other things, merely carried about the person, have the power both of repelling and of healing diseases. Even the celebrated Robert Boyle adopts this notion, assuring us that he once experienced the efficacy of such an amulet in his own case. "Having been one summer," he says, "frequently subject to bleed at the nose, and reduced to employ several remedies to check that distemper; that which I found the most effectual to stanch the blood was some moss of a dead man's skull (sent for a present out of Ireland, where it is far less rare than in most other countries), though it did but touch my skin till the herb was a little warmed by it." ('Essay of the Porousness of Animal Bodies.' See also his 'Essays on the Usefulness of Natural Philosophy,' and his 'Experimental Discourse on some Unheeded Causes of the Insalubrity and Salubrity of the Air.') The anodyne necklace, which consists of beads formed from the roots of white bryony, and is sometimes hung around the necks of infants with the view of assisting their teething, is an instance of the still surviving confidence in the medical virtue of amulets. Such also is the belief generally entertained by seafaring people, that a child's caul on board their ship will preserve them from being lost—and many other examples might be easily quoted. Even in 1858, though probably without much superstitious belief, *charms* were advertised set as jewels, and among them were pieces of the Atlantic cable.

AMYGDALIC ACID. ($C_{40}H_{26}O_{24}$). Produced by the action of alkalies upon amygdalin.

$$\underbrace{C_{40}H_{27}NO_{22}}_{\text{Amygdalin.}} + 2HO = \underbrace{C_{40}H_{26}O_{24}}_{\text{Amygdalic acid.}} + NH_3.$$

Evaporated on the water-bath, solution of amygdalic acid dries up to a gummy mass, which is highly deliquescent, insoluble in ether, and in boiling absolute alcohol. By the aid of heat it reduces the salts of silver. Its salts are generally gummy and uncrystallisable. Like amygdalic acid itself, they yield formic acid, carbonic acid, and hydride of benzöyl, when boiled with a mixture of peroxide of manganese and sulphuric acid.

AMYGDALIN. ($C_{40}H_{27}NO_{22}+6aq.$) A crystalline substance first obtained by Robiquet, and Boutron Charlard, and afterwards studied by

Liebig and Wöhler. It is met with in bitter almonds, the leaves of the cherry laurel, the kernels of peaches, and is probably also contained in all those parts of vegetables which yield hydrocyanic acid when distilled with water.

Amygdalin is prepared as follows:—Bitter almonds are strongly pressed between hot plates of iron, so as to expel the fixed oil they contain. The resulting mass is extracted with boiling alcohol of 90 or 95 per cent., and to the filtered and clarified alcoholic solution, evaporated to one-sixth its volume, is added half its bulk of ether, which precipitates the whole of the amygdalin. The precipitate is finally washed with ether and purified by recrystallisation from alcohol. Four pounds of bitter almonds yield about an ounce of amygdalin.

Amygdalin crystallises in white pearly plates, which are very slightly soluble in cold, but easily soluble in boiling absolute alcohol. It dissolves readily in water, but is insoluble in ether. Its aqueous solution possesses a slightly bitter taste. The most interesting property of amygdalin is, that when its solution is placed in contact with *emulsin*, it is transformed by a species of fermentation into hydrocyanic acid, hydride of benzöyl (essential oil of bitter almonds), and grape sugar.

$$\underbrace{C_{40}H_{27}NO_{22}}_{\text{Amygdalin.}} + 4HO = \underbrace{C_2HN}_{\text{Hydrocyanic Acid.}} + \underbrace{C_{14}H_6O_2}_{\text{Hydride of Benzöyl.}} + \underbrace{2C_{12}H_{12}O_{12}}_{\text{Grape sugar.}}$$

Bitter almonds contain both amygdalin and emulsin, and, therefore, when treated with water they yield the well known essential oil mixed with hydrocyanic acid; but sweet almonds contain emulsin and no amygdalin, and consequently do not yield these products when macerated with water.

AMY'GDALUS—*Medical Properties of. Amygdalus communis*, a tree native of Asia and Africa, cultivated in the southern parts of Europe, of which there are two varieties, sweet and bitter. Of the sweet almonds, the parts which are officinal are the seeds or kernels. When covered with the skin, these are of a clove-brown colour, smooth, with vessels traversing the skin, and forming a raphe. Deprived of the skin, the egg-shaped seed, formed of two cotyledons, is seen of a white colour. They have a sweet and mucilaginous, rather oily taste, and scarcely any odour when fresh but when spoiled a disagreeable rancid taste.

Analysed by Boullay, they yielded emulsin, and a fat oil of a very bland kind. Ten pounds of seeds yield four pounds of oil. Upon being subjected to pressure, or treated by means of ether, the oil is separated, and there remains the cake, or farina amygdalæ. The commercial varieties are numerous, but the most esteemed are the Jordan almonds.

Triturated with water, sweet almonds form a grateful, sweetish emulsion, which possesses considerable nutritious as well as demulcent properties. This emulsion should never be prepared long before it is required for use, and should always be made with sweet almonds. Almond-paste forms a good emollient application to chapped hands in winter.

Almonds, as an article of dessert, are nutritive, but rather indigestible. In some persons they occasion—more particularly bitter almonds—an eruption similar to nettle-rash, and other troublesome symptoms.

Oil of Almonds.—The almonds having been freed from the skins, must be bruised, and pressed in the cold, or, if warmed, they must be pressed in iron presses. The oil when first obtained is turbid, but becomes pure by time or by filtration. It is yellowish, or nearly white, if the almonds have been completely freed from the skins before being pressed, translucent, and when cold-drawn is without odour. The taste is purely oily. Specific gravity, 0·911 to 0·920. Consists of, elain 75; stearin 25. It is fluid at the ordinary temperature of the air, and rarely or never becomes turbid or white. Alcohol when cold takes up 1-25th part. Sulphuric ether and the volatile oils combine with it in every proportion. Caustic potash forms with it a very solid soap. When it has been carefully expressed, it does not become rancid so easily as is believed.

It may be obtained from either variety, but is yielded in greatest abundance by the bitter almond: 10 lbs. of sweet, when cold-drawn, yield from 4 to 4½ lbs.; 16 lbs. of bitter almonds yield 7 lbs.

Almonds which have become rancid yet yield by expression good oil, if a little calcined magnesia be added to the bruised almonds before being subjected to pressure.

Almond oil is often adulterated with poppy oil. It is employed more as an external application, especially to the ears, than internally. It is also used for hair oil.

Amygdal. Amaræ, bitter almonds, are smaller and flatter than the sweet. Those most esteemed come from Provence; those least esteemed from Barbary. They have a very bitter taste, and scarcely any odour, but if rubbed between the fingers with a little water, they emit a peculiarly agreeable odour. Triturated with water, they form an emulsion, which by distillation yields a volatile oil, containing hydrocyanic acid. This oil is procured in very variable quantity; 1 lb. of almonds yielding in some instances 1 drachm, in others only 50 grains, in others only 10 grains.

A fat or fixed oil is also contained, which may be procured by expression. Hence, in the Pharmacopœia, Oleum amygdalarum is directed to be expressed from the kernels of either variety. For the sake of economy, this fixed oil is first procured, and the cake which remains is employed either to yield the volatile oil containing hydrocyanic acid or to furnish amygdalin.

The essential oil of bitter almonds is prepared by distilling the emulsion of bitter almonds.

It is sold in different degrees of dilution to cooks, confectioners, and others, to flavour cakes and liqueurs, under the name of essence of ratafia, peach-essence, &c. (See 'Lancet,' June 8, 1844; and 'The Chemist,' vol. v. p. 335.) From its indiscriminate use, as well as variable strength, many fatal cases result from it. It is also used as a criminal means of destroying life. [AMYGDALIN; BENZOYL, HYDRIDE OF.]

AMYL ($C^{10}H^{11}$) or $\left(\begin{matrix}C_{10}H_{11}\\C_{10}H_{11}\end{matrix}\right\}\Big)$. A compound radical, discovered by Frankland. It is procured by the action of zinc on iodide of amyl. It is an oily liquid, boiling at a temperature of 311° Fahr., and is homologous with methyl, ethyl, &c. Its compounds form a series of highly interesting bodies, resembling those containing ethyl and methyl.

The following are some of the most important of these compounds:—

Hydrated oxide of amyl (Amylic alcohol) $\left(\begin{matrix}C_{10}H_{11}\\H\end{matrix}\right\}O_2\Big)$. This body, from which amyl and all its compounds are derived, is formed along with common alcohol during the fermentation of the mash of potato starch, and the starch of common grains. The process of its formation under these circumstances is not well understood, although it undoubtedly depends on some peculiar conditions of the fermentation. It is on account of its being obtained from the decomposition of starch (*Amylum*) that it has obtained its name. The latter portions of the alcohol produced in the distillation of these fermented matters contain an oil separable by water and termed *Fusel oil*, the greater portion of which consists of amylic alcohol. It is the occurrence of this oil in crude distilled spirits that gives them a part of their noxious qualities, and it is the object of the distiller to prevent the development of fusel oil. When fusel oil is submitted to distillation, its boiling point gradually rises until it reaches 270° F., at which point it then frequently remains stationary during the remainder of the distillation. The portion of the fusel oil distilling at 270° is pure hydrated oxide of amyl. It is a colourless, somewhat oily liquid, almost insoluble in water, and boiling at a temperature of 270°. It has a powerful odour, which is very unpleasant, and produces when inhaled a sense of suffocation. Its taste is nauseous and acrid. When heated in contact with potash, hydrogen is given off, and valeric acid is formed, which unites with the potash. Distilled with a mixture of dilute sulphuric acid and bichromate of potash, it also yields valeric acid,

$$\underbrace{C_{10}H_{12}O_2}_{\text{Amylic alcohol.}} + O_4 = \underbrace{C_{10}H_{10}O_4}_{\text{Valeric acid.}} + 2\,HO.$$

and is now the source of the salts of this acid used in medicine. When heated with dry phosphoric acid, it yields the carbo-hydrogen $C^{10}H^{10}$, which is isomeric with olefiant gas, and which is known by the name of *Amylene* or *Valerene*. This substance has lately obtained some repute, since it has been administered in common with chloroform and ether as an anæsthetic. [ANÆSTHETICS; MATERIA MEDICA; ALCOHOLS.]

Iodide of Amyl ($C_{10}H_{11}I$).—This compound is formed by distilling together a mixture of 10 parts of amylic alcohol, 12 parts of iodine, and 1¼ parts of phosphorus. The product, after being washed with water, and then dried over chloride of calcium, is again submitted to rectification, a thermometer being inserted through the tubulure of the retort. That portion which distils over whilst the thermometer stands at 295° F. is pure iodide of amyl, and must be collected apart.

Iodide of amyl is a colourless and transparent liquid, refracting light strongly, possessing a slight ethereal odour and a pungent taste. Its specific gravity is 1·511. It boils at 295° F. Exposed to direct sunlight, it gradually becomes brown from the separation of free iodine. It is decomposed by an alcoholic solution of potash, amylic alcohol being reproduced.

$$\underbrace{C_{10}H_{11}I}_{\text{Iodide of amyl.}} + \underbrace{KO,HO}_{\text{Hydrate of potash.}} = \underbrace{C_{10}H_{12}O_2}_{\text{Amylic alcohol.}} + \underbrace{KI.}_{\text{Iodide of potassium.}}$$

Heated with amalgam of zinc to 356° F., in a strong sealed glass tube, it gives amyl, hydride of amyl, amylene, and iodide of zinc. Heated to 212° F. with alcoholic solution of ammonia, it yields amylamine.

The following are the names and formulæ of the remaining more important compounds of amyl:—

Oxide of amyl	$C_{10}H_{11}O,\ C_{10}H_{11}O$
Chloride of amyl	$C_{10}H_{11}Cl$
Bromide of amyl	$C_{10}H_{11}Br$
Sulphide of amyl	$C_{10}H_{11}S$
Amylamine	$C_{10}H_{13}N$
Diamylamine	$C_{20}H_{23}N$
Triamylamine	$C_{30}H_{33}N$

Zincamyl	$C_{10}H_{11}Zn$
Sulphamylic acid	$C_{10}H_{11}O, SO_3HOSO_3$
Hydride of amyl	$C_{10}H_{11}H$
Nitrate of amyl	$C_{10}H_{11}ONO_5$
Acetate of amyl (Pear oil)	$C_{10}H_{11}OC_4H_3O_3$
Valerate of amyl (Apple oil)	$C_{10}H_{11}OC_{10}H_9O_3$
Amylurea	$C_{12}H_{14}N_2O_2$
Amylphenylamine	$C_{22}H_{17}N$
Amyldiethylamine	$C_{18}H_{21}N$

AMYLAMINE. [AMYL.]

AMYLENE. [AMYL.]

AMYLUREA. [AMYL.]

AMYLIC ALCOHOL. [AMYL.]

AMYRINE. A resinous substance of unknown composition, extracted from the *Canarium album*, a tree growing in the Philippine islands. It is soluble in ether, from which it crystallises in lustrous satiny fibres. It is insoluble in water, soluble in hot absolute alcohol, and fuses at 345° Fah.

ANA, a Latin termination of the neuter plural form. It appears in our language, divested of the sign of gender, number, and case, in such words as subterranean, metropolitan, Christian, Anglican, Ciceronian, Johnsonian. The Latin *ana* is the form appropriated to the neuter plural; and, therefore, *Ciceroniana*, for instance, would signify matters, or things of any sort, about or appertaining to Cicero. Cicero, in one of his epistles, mentions an *ana* (book vii. ch. 32), in which he complains of having all sorts of sayings attributed to him, even the Sextiana.

In modern times this termination has been used to denote collections, either of remarks made by celebrated individuals in conversation, or of extracts from their note-books, letters, or even published works, or generally, of particulars respecting them.

The earliest recorded modern *ana* were certain manuscript collections in the possession of Guy Patin, in 1659, relating to Grotius, Nicholas Bourbon, and Gabriel Naudé, which he called Grotiana, Borboniana, and Naudeana. They were never published; those published as 'Naudeana' at Paris in 1701, being, as is generally acknowledged, a mere forgery.

The first printed Ana was the collection of the colloquial remarks of Joseph Scaliger, now distinguished as the 'Scaligerana Secunda.' Two brothers, Jean and Nicholas de Vassan, having gone to study at Leyden, carried with them letters of recommendation from Casaubon to Scaliger, who was then one of the professors in that university. In consequence they were much at his house, and heard a great deal of his conversation, both in company and in private. Such of his observations upon all sorts of subjects as they considered to be most valuable or remarkable they wrote down till the collection at last formed a thick octavo volume. The book was published in 1666, with the title of 'Scaligeriana, sive Excerpta ex ore Josephi Scaligeri:' per FF. PP. (contraction for 'Fratres Puteanos').

It happened, however, that the Vassans were not the only persons by whom Scaliger's conversations had been noted down. A physician of the name of François Vertunien, who attended the family of the MM. Chateigners de la Rochepozai, in whose house Scaliger resided, had been in the habit for seventeen years, namely, from 1575 to 1592, of keeping a record of the remarks that dropped from the lips of the great scholar. After his death they were published along with the former collection, in 1669, bearing the following title, 'Prima Scaligerana, nusquam antehac edita, cum Prefatione T. Fabri; quibus adjuncta et altera Scaligerana, quam antea emendatiora, cum notis cujusdam V.D. anonymi.'

The next of the Ana which appeared was the 'Perroniana,' being notes (in French) of the conversations of Cardinal du Perron. It appeared in 1669. In the same year, the same person gave to the world another of these collections, the 'Thouana,' or remarks of the President de Thou. These works had extraordinary success; and the avidity with which they were read, produced a long succession of similar productions. It was in France, or at least in the French language, that most of the Ana appeared; and their popularity may be said to have lasted for fully half a century. One of the most valuable of this class of publications is the 'Menagiana,' a record of the conversations of Menage, who was a man of distinguished wit and talent, as well as a great scholar. He died in 1692, and the following year the 'Menagiana' appeared in a 12mo volume, both at Paris and Amsterdam.

Of our English *Ana*, by far the most celebrated is the 'Walpoliana,' being a collection of the conversational remarks of Horace Walpole.

There are many works, which, without bearing the characteristic title of such collections, belong in all other respects to the class of the *Ana*. One of the earliest and most celebrated of such works in modern times is the 'Colloquia,' or 'Table-Talk' of Luther, first published in German at Eisleben, in 1565. Another very celebrated work of this kind is the 'Table-Talk of John Selden,' which is stated to have been collected by Richard Milward, and was first published in 1689. Boswell's 'Life of Johnson' is undoubtedly the most remarkable work of this description in existence.

ANABAPTISTS, a religious sect. The word, composed of two Greek terms, properly signifies those who baptise a second time, or insist upon the necessity of a second baptism in persons whom they admit to their communion. It is sometimes applied to designate that large body of Christians in our own and other Protestant countries, one of whose articles of belief is, that baptism ought only to be administered to adults, and who, accordingly, rebaptise those who seek to join them. But this application of the name is quite unwarranted, and one against which the community in question have always protested. They do not maintain the necessity of a new or second baptism, nor are those who have been born and brought up in their persuasion ever baptised twice. Others, who may have been previously baptised in infancy, are indeed baptised once again when they have grown up; but this is done on the principle that the former ceremony was no baptism at all. *Baptists* is the designation assumed by those who thus hold the doctrines of the non-validity of infant, and the necessity of adult, baptism; and they will accordingly be properly noticed under that head.

We are not aware, indeed, that there has ever been a sect which maintained the necessity of two successive baptisms. On the other hand, it is certain that there were various sects in the earlier ages of the church which agreed with the modern Baptists in allowing no validity except to adult baptism. But the epithet Anabaptists appears to have been first employed to describe a body of fanatics who made their appearance in Germany soon after the commencement of the Reformation; and although it has been since frequently applied to other religious bodies as being alleged to have sprung from these, such a use of it can only be considered as one of those imputations with which different sects have been in the habit of assailing each other.

The Anabaptists were, no doubt, the growth of the Reformation—though Protestant writers have laboured hard to make it appear that such was not the case. They were the ultra-radicals of the Reformation. Munzer, Stubner, and Storck, who were the first heads and apostles of the sect, had all been disciples of Luther; although no person could have more earnestly condemned their proceedings than did that great reformer. They first began to preach their peculiar doctrines in the town of Wittenberg, in Saxony, in the year 1521. In 1525, their followers, composed almost exclusively of the lowest rabble, rose in a general rebellion against the established authorities throughout that province, Suabia, Thuringia, and Franconia. But this insurrection, which it is but fair to remark was partly of a political character, and occasioned by the oppression to which the peasantry were subjected, was soon defeated; and Munzer, himself, being taken, was put to death. The novel notions, however, which he had preached, spread as usual under persecution; and, some years afterwards, the mischief broke out again with new fury. In 1532 a numerous mob of these fanatics, conducted by John Matthias, a baker, of Haarlem, and John Boccoldt, a tailor, of Leyden, suddenly attacked the city of Münster during the night, and made themselves masters of the place. Their adherents immediately flocked thither from all quarters: and elated by their success, the congregated enthusiasts are stated to have given themselves up to extravagances far exceeding anything they had before practised. Matthias named Münster Mount Zion, and proclaimed himself its king. Having madly undertaken, however, attended with only thirty followers, to attack and disperse the forces which came to recover the town, he perished, with all who accompanied him. John of Leyden now assumed the royal dignity, and under his conduct the multitude is said to have proceeded to wilder excesses than ever. The city, however, was at length recaptured by the army which the Bishop had brought up against it on the 24th of June 1535; and Boccoldt, having fallen into the hands of the victors, was soon after executed with the most terrific cruelties that hatred and revenge could dictate.

The most extravagant tenets, as well as conduct, have been commonly ascribed to the Anabaptists of Münster; but the accounts of a proscribed sect by their enemies, it is to be remembered, are scarcely to be received with implicit credit. The doctrine which gave occasion to their distinctive appellation was one of the least remarkable of all their peculiar articles of belief, although they are said to have inculcated it with singular emphasis and vehemence, being in the habit of declaring that infant baptism was an invention of the devil. A much more pernicious principle which they are accused of having held, at least in so far as the peace of society was concerned, was that of the unwarrantableness of all civil government, and the emancipation of the faithful from subjection to either laws or taxes. They are also said to have maintained that, among the saints, all things ought to be in common. Their speculative theology is described as having been much the same with that which has been, and still is, patronised by various other denominations of enthusiasts. It rested principally on the notion that God made his will known to them individually by special inspirations, by way of enhancing the importance of which they are said to have expressed themselves with some degree almost of contempt or disparagement of the written word. Besides the internal impressions which they called inspirations, they had dreams and visions in which they put much confidence; and some of them conceived themselves to have the gift of prophecy, which they were especially accustomed to exercise in predicting the speedy approach of the end of the world. Akin to these delusions was another favourite and fundamental dogma, that every true believer attained even in this life perfect freedom from sin. This position soon led them a great way. Finding that what had commonly been called sin could not be altogether extirpated from the bosoms even of the stoutest believers, they found it necessary, in order to save the doctrine, to declare that certain things which had hitherto been deemed contrary to the divine law, were not so at all, but in reality either indifferent or meritorious. It does not appear that they are accused of having gone quite to the extreme to which the principle in question has sometimes led, of maintaining generally that the belief of the sinner sanctified or neutralised his sin, or, in other words, that an act which would have been sinful in another became divested of its sinful character when committed by a believer. If all that is stated of them be true, indeed, they were under no necessity to resort to this device in order to give a loose to their inclinations, having put down in their list of universally permissible indulgences most of those things to which there is any violent disposition in the multitude of mankind. They condemned, for instance, with great severity, all ornamental attire, and some even went the length of objecting to clothing altogether. Boccoldt himself, in one of his fits of exaltation, solemnly promenaded the streets of Münster, stark naked. The love of dress, they said, was an artificial vanity, and as such hateful to God. But whatever, on the other hand, they held to be natural, they looked upon as harmless or commendable. Boccoldt is stated to have urged upon his followers, as in the highest degree conducive to their spiritual welfare, the practice of a liberal polygamy, and to have illustrated and enforced his doctrine by taking to himself no fewer than fourteen wives.

For a long time after the events which have been related, it was dangerous in Germany and other parts of the continent to profess an adherence to the doctrine of adult baptism; those who held that tenet being all most absurdly classed as belonging to the sect of the Anabaptists of Münster. It has been commonly said, that to avoid the persecution to which they were subjected, the remains of these fanatics in course of time adopted various new denominations, some congregations calling themselves Mennonites, after an eminent leader of the sect, others Waterlandians, from the place of their principal church, others Baptists, &c. But there is really no proof that any of the communities bearing these names had, in their origin, any connection whatever with the Münster insurgents. For further information on the subject of the Münster Anabaptists, the reader may be directed to Mosheim's 'Ecclesiastical History,' century xvi. section iii., part ii., chapter iii. and century xvii., section ii., part ii., chapter v., where he will find the subject treated with great learning, though not in a spirit of much liberality or candour. The principal works relating to the Anabaptists are all referred to in that dissertation.

ANA'BASIS, the title of a Greek work, in seven books by Xenophon of Athens, which describes the circumstances of an expedition undertaken by the younger Cyrus, B.C. 401, against his brother, Artaxerxes, king of Persia. The expedition is remarkable as being the first long march of which we possess a detailed account, and also the oldest extant document which gave to Europeans any tolerably precise notion of the country watered by the Upper Tigris and Euphrates.

The army of Cyrus contained a large body of Greek mercenaries, among whom Xenophon, at first, held no military rank: he went apparently as a mere spectator, and only took command after the death of most of the generals. Cyrus set out from Sardes (now Sart), 38° 34′ N. lat., 28° E. long., and marched through Asia Minor to the passes in Mount Taurus, that lead into Cilicia. He next passed through Tarsus, along the Gulf of Scanderoon, and through the north part of Syria to the Euphrates, which he crossed at Thapsacus, about 35° 14′ N. lat. He then marched S.E. through Mesopotamia, crossing the Araxes (the Khabour); and finally lost his life in an engagement with his brother on the plains of Cunaxa (the site of which is unknown), about forty miles from Babylon (now Hillah), 32° 28′ N. lat., 44° 14′ E. long.

From this point commenced the retreat, commonly known as the "Retreat of the Ten Thousand." Instead of returning by the way which they came, it was determined to reach some of the Greek colonies on the Black Sea. Accordingly they crossed the Tigris, and advancing along the east bank of this river up the stream, they crossed in succession the Diala and other tributaries of the Tigris. They followed the course of this river, till they were stopped about 37° 20′ N. lat. by the mountains pressing close on the river, and allowing no passage along its banks. They then crossed the mountains, and advanced probably nearly due north, but their course from this point is very uncertain. It is probable that the army passed to the west of Lake Van, and in its progress it must have crossed the Morad, or Eastern Euphrates, and that branch of the Araxes which is now the Faz, and is called by Xenophon the Phasis. After enduring much hardship from snow, want of food and clothing, and the opposition of the native tribes, the army at last reached Trapezus, now Trebizond, on the Black Sea, in 41° 2′ N. lat., 39° 28¼′ E. long. From Trapezus the army marched along the coast westwards for about 100 miles (direct distance) to Cotyora.

The narrative of Xenophon contains a statement of the army's marches, with some few omissions, expressed in Persian parasangs, at the rate of thirty stadia to a parasang. The following are the distances given by him in round numbers:—

	Stadia.
From Ephesus to Cunaxa	16,050
From Cunaxa to Cotyora (eight months)	18,600
	34,650

Xenophon adds the march of the Greek auxiliaries from Ephesus to Sardes (about fifty miles) to the distance from Sardes to Cunaxa.

The march may be considered as having terminated at Cotyora, as the army sailed from this place to Sinope, now Sinub: their troubles, however, continued till they reached Byzantium, now Constantinople, and even beyond that point.

If we take the stadia of Xenophon at the rate of ten to a mile, an estimate which is above the truth, we find the whole distance marched to be 3465 English miles, which was accomplished in fifteen months, and a large part of it through an unknown mountainous and hostile country, and in an inclement season. The reader will find the expedition of the younger Cyrus discussed in the work of Major Rennel, and the various difficulties that occur in the narrative of Xenophon explained, as far as means of information will allow, with the Major's usual good sense and sagacity. [XENOPHON, in BIOG. DIV.]

Anabasis is also the name given by Arrian, who was in all things an imitator of Xenophon, to his work, in seven books, in which he describes the campaigns of Alexander the Great. [ARRIAN, in the Division of BIOGRAPHY.]

ANACARDIC ACID. ($C_{44}H_{32}O_7$?) A white crystalline aromatic acid contained in the shell of the acajou nut.

ANÆMIA, a diseased condition of the human body, in which is implied either a morbid condition of the blood, or a relative diminution of some of its most important constituents. This disease is also called *oligonæmia* and *spanæmia*, terms which, like anæmia, express a deficiency or paucity of the constituents of the blood. This state of the system is generally indicated by the excessive paleness of the face and the whole surface of the body. The lips are pale. The conjunctiva is of an unnatural white, having a pearly lustre. The veins on the surface are small, blue, and collapsed. These general symptoms are frequently attended with derangements of the nervous system. There is frequently violent pain in the head, and not unfrequently disordered sensation, as singing in the ears and flashings before the eyes. The whole surface of the body is frequently preternaturally tender, the slightest touch causing the patient to start. The course of the spine is often excessively tender, leading to the supposition that there is spinal irritation. The circulating system is deranged; palpitations of the heart come on after slight exertion. The pulse is mostly small, feeble, and quick, excited to rapid action on slight exertions. The breathing is quickened by exertion, and there is generally lassitude and inability to take much exercise. This disease is accompanied with disturbances of the circulating system, which may be detected by means of the stethoscope. These are heard in the heart, arteries, and veins. The sound heard in the heart is a "bellows" murmur of varying intensity, and is heard most distinctly at the apex. This sound is not present in all cases of anæmia, nor is its occurrence diagnostic of anæmia; but it is very important to know that it may be entirely dependent on the anæmic condition, and removed with it. The arterial murmurs are not frequently heard; they are synchronous with the beat of the pulse, and when present may even be recognised by the character of the pulse. The venous murmurs are much more common. They are continuous, and produce various buzzing, humming, musical, and singing murmurs. "They are most frequently heard on the right side of the neck, at the junction of the external and internal jugular vein." (Aitken.)

The venous murmurs are seldom absent to a greater or less extent in anæmia.

When the blood of anæmic persons is examined under the microscope a deficiency of blood globules is observed. Andral records a case in which there were but 30 parts of blood globules in 1000 of blood. The other constituents of the blood, as far as observations at present go, seem to suffer little alteration.

The *causes* of anæmia are anything acting on the system by which the quantity of blood is diminished or the healthy development of the blood cells prevented. Thus, amongst the causes of this disease we may reckon: 1. Want of food. 2. Want of proper food. 3. Indigestion or imperfect nutrition, from whatever cause. 4. Derangement of the liver, spleen, &c. 5. Hæmorrhages, as from hæmorrhoids, the stomach, lungs, wounds, &c. 6. All extensive discharges from wounds, ulcers, or mucous surfaces.

A knowledge of the causes of anæmia at once suggests its treatment. Where it depends on a want of food altogether, or of proper food, then food of a proper kind must be supplied. Where improper food, as alcohol, produces imperfect assimilation, it must be withdrawn. Deficient nutritionary changes often come on as the result of impure air, and change from an impure to a pure air often acts most beneficially. In certain cases dependent on imperfect blood-cell formation great benefit results from the administration of iron. Cases are recorded in which, under an iron treatment, the blood-cells have increased from 32 to 95 in 1000. Other tonics may also be administered with advantage. In cases of anæmia in marshy districts quinine is of great service.

ANÆSTHETICS, is the term applied to those agents, which, on being applied or administered to the human body, produce either a local or general insensibility. Such agents act more especially on certain parts of the nervous system, depriving it both of its power of communicating and perceiving impressions made upon its sensitive function. The state of anæsthesia comes on in various forms of paralytic disease, and as such has been known and described by medical writers. Anæsthesia can also be produced by artificial means, as in those states of the nervous system brought on by what is called animal magnetism. In this state of the system the anæsthesia is sometimes so perfect that surgical operations have been performed on persons whilst in it perfectly unconsciously. This was known previous to the general introduction of anæsthetic agents during the performance of surgical operations generally. All narcotic medicines will produce conditions of anæsthesia, in which surgical operations may be performed without pain. During the action of alcohol on the nervous system in drunkenness, operations have been performed without the knowledge of the patient. Although these circumstances have been generally known, it was not till about the year 1847 that any attempt was made to introduce anæsthetic agents as a means of alleviating pain during the performance of surgical operations. About this time, two gentlemen in America, Drs. Morton and Jackson, made experiments on human beings with the nitrous oxide (laughing gas), and found that a state of insensibility could be produced by its agency, under which operations could be performed. The effects of this gas in producing excitement of the nervous system had been made known by the experiments of Sir Humphry Davy, and its peculiar action was often exhibited in the lecture-room of the chemist. It was also known that sulphuric ether produced similar effects on the human system. The merit however of the application of these remedies to the production of insensibility during the performance of surgical operations is due to Drs. Morton and Jackson. Having discovered that ether was much preferable for this purpose to nitrous oxide, they made known the important fact, that under the influence of this agent an insensibility might be produced under which persons might undergo the most severe operations without pain, and might be restored from this condition without injury to their health. This announcement was speedily made known, and in the course of a few months the facts were realised in all parts of the world. In London the action of this agent was extensively tried, and realised the most sanguine expectations. The action of ether, and the best method of administering its vapour, was investigated by Dr. John Snow, who, in September 1849, published a work on the 'Inhalation of the Vapour of Ether.' After the success of the first experiments with ether, it was found that other agents similarly constituted acted in the same way upon the human system. This subject was investigated with great success in Edinburgh, and led to the discovery by Dr. Simpson of that city, that chloroform, a terchloride of formyle, acted more speedily and efficaciously than even ether. From this time chloroform became more generally used, and is now the substance which is generally employed for the production of artificial anæsthesia. After this, Dr. Snow found that amylene was capable of producing the same effects as chloroform.

These agents appear to act entirely through the nervous system, and according to the time employed in their administration will be their effect on the nervous centres. The first part of the nervous system which appears to be affected is the brain, and a kind of intoxication comes on in which the patient is excited, the intellectual powers are deranged, and the person acts as though drunk. This effect is produced much more quickly by the vapours of the above-mentioned substances than by drinking alcohol; it also passes off much more rapidly. It was to this action more especially that the effects of the nitrous oxide and ether were confined previous to the discovery of their anæsthetic properties. If however the use of the vapour is persevered in, the effect extends from the brain to the cerebellum, and this organ loses the power of regulating the movements of the body. This effect on the body is also produced by the drinking of alcohol. As the vapour continues to act on the system, the next nervous centre affected is the spinal chord, and the functions of sensation and motion more immediately under the control of this part of the nervous system, are more or less affected. It is in this stage that consciousness and the powers of motion and sensation are entirely lost, and the individual is pronounced in a state of anæsthesia. In this condition animal life is held in abeyance, and the body is insensible to all external agents. There is still however a sufficient amount of nervous power left to maintain the functions of organic life. The heart beats, the lungs perform their functions, and other actions essential to life are carried on. These functions are however under the influence of these anæsthetic agents, and should too large a dose of them be administered, they cease, and death ensues. This is one of the accidents to which the employment of these remedies is exposed, and against which the greatest precaution should be employed.

Dr. Snow, who has practically studied the agency of these remedies more extensively than any other writer, divides the action of ether into five stages. "In the *first degree* the person experiences various changes of feeling, but still retains a correct consciousness of where he is, and what is occurring around him, and a capacity to direct his voluntary movements. In this stage the patient's feelings are generally agreeable, often highly so. In this stage it is not practicable to perform operations without a certain amount of pain. When, however, persons have experienced the more intense degrees of the anæsthetic agent, they return to this stage, and are free from the pain of an operation, whilst their consciousness has sufficiently returned to enable them to know what is going on. In the *second degree* the mental functions may be exercised and voluntary actions performed, but in a disordered manner. In this stage persons are often seized with a tendency to laugh, sob, or scream. They throw themselves about, their actions are instinctive, and not under the direction of their intelligence. In this stage it is not advisable to perform operations, and many operators not carrying the action of the anæsthetic further than this stage have regarded it as useless. The patient may return to this stage from a further one, but it is most desirable that operations should not be performed in it. In the *third degree* there is no evidence of any mental function being exercised, consequently no voluntary motions occur, but muscular contractions in addition to those concerned in respiration may occur. There is sometimes great rigidity of the muscles, but more frequently this is not present. There is a tendency to moan, but not to utter any articulate sounds."—"If this degree is well established, and if the patient has been detained in it at the same point, by inhaling at intervals, or by inhaling dilute vapour, an operation may usually be performed without producing any other effect than a distortion of the features expressive of pain, and perhaps a slight moaning and an increased frequency of respiration, and in some instances a general rigidity of the muscular system." There is never any recollection of operations in this degree, even when symptoms of pain have been exhibited.

In the *fourth degree* no movements are seen, except those of respiration, and they are incapable of being influenced by external impressions. All the muscles are relaxed, and the limbs hang down, or rest in any position in which they are supported. The breathing is deep, regular, and automatic, and there is much snoring. In this degree the patient always remains perfectly passive under every kind of operation. It lasts seldom more than two or three minutes after the inhalation is discontinued. The integrity of the functions of respiration and circulation is not impaired. The pulse is distinct, and however much deranged in previous stages, is little disturbed in this; the sensibility of the glottis and pharynx is maintained, and the patient swallows without difficulty. In the *fifth degree* the movements of respiration and circulation become impaired, and every care should be taken to prevent the action of the vapour from arriving at this point, as death may shortly ensue.

With regard to the quantity of ether required, and the time necessary, Dr. Snow makes the following remarks: "If a middle-aged man, about the average size, is supplied with air mixed with vapour of ether in the proportion of 45 per cent. vapour to 55 per cent. air, and breathes it easily and without obstruction, he usually consumes about two drachms of ether per minute. It is not all absorbed, for a part is expired after passing no further than the trachea. At the end of the first minute he is usually in the first degree of etherisation; of the second minute in the second degree; of the third minute in the third degree; and at the end of four minutes, having inhaled an ounce of ether, in the fourth degree. If the inhalation is now discontinued, he commonly remains in this degree of etherisation for one or two minutes, passes gradually back into the third degree, which lasts for three or four minutes, at the end of which time he is in the second degree, which lasts about five minutes, to give place to a feeling of intoxication and exhilaration, which lasts for ten or fifteen minutes, or longer, before it entirely subsides."

The general effects of chloroform resemble closely those of ether. It is, however, a more potent remedy, and produces anæsthesia more rapidly and certainly than ether. Hence it has been employed more generally. This substance was originally discovered by Liebig and Soubeiran in 1831, and its chemical nature was investigated by Dumas. He first pointed out that the liquid which had been called chloric ether, and chloride of carbon, was composed as follows, $C_2\,H\,Cl_3$, and called it chloroform. Liebig subsequently pointed out that it was a terchloride or perchloride of the base formyle. This substance is prepared, according to the Pharmacopœia of the London College of Physicians, as follows: Take of chlorinated lime iv. lb.; rectified spirit Oss; water Ox; chloride of calcium broken into pieces ℥j. Put the chlorinated lime first mixed with the water into a retort, and then add the spirit, so that the mixture may fill only a third part of the retort. It is then heated in a sand-bath, and as soon as ebullition begins, the heat is withdrawn. The liquid is then distilled into a receiver. A quart of water is then added to the distilled liquid and well shaken. The heavier portion which subsides is then separated, and the chloride of calcium added to it, and frequently shaken for an hour. The liquid, which is the chloroform, is again distilled from a glass retort into a glass receiver. It is a transparent colourless liquid, having a specific gravity of 1·48. It boils at 140° Fah., and the density of its vapour is 4·2. It has a fragrant ethereal apple-like odour, and a slightly acid sweet taste. It is soluble in alcohol and ether, but requires 2000 parts of water for its solution. It dissolves camphor, Indian-rubber, wax, and resins. It is not inflammable. This substance is sometimes given internally in doses of from five to ten minims, and acts as a stimulant sedative antispasmodic and anæsthetic.

Administered in the form of vapour as an anæsthetic, chloroform is much more powerful than ether. This effect seems to arise from its being much more sparingly soluble in the blood than ether. "The quantity of chloroform," says Dr. Snow, "required to induce insensibility is less than one-tenth as much by measure as in the case of ether. Viewed in this manner, it is more than ten times as strong; but to ascertain their comparative physiological power, when inhaled in a similar manner, their volatility requires to be taken into account. In order to perceive the relative strength of these two medicines, we may suppose that the air which a patient breathes is saturated at 60°,—the ordinary temperature of a dwelling room,—with one or other of the vapours, and see how much air he would have to breathe in either case in order to be narcotised to the third degree,—the extent of insensibility usually required in a surgical operation. Thirty-six minims is about the average quantity of chloroform required to produce this degree of narcotism in the adult, and this would saturate 257 cubic inches of air at 60°, making it expand to nearly 300 cubic inches, which would be breathed in 12 ordinary respirations of 25 cubic inches each. The quantity of ether usually required to produce the same amount of insensibility in the adult, is about 7½ fluid drachms; this would saturate 440 cubic inches of air at 60°, and increase its volume to rather more than 800 cubic inches, which would require 32 ordinary respirations to breathe it. We see, therefore, that 12 inspirations of air charged with vapour of chloroform are equal to 32 similar inspirations of air charged with vapour of ether, at the same temperature; and that, consequently, choloroform is nearly three times as strong as ether. In actual practice the difference in strength is generally greater than this, for ether abstracts much more caloric than chloroform during its evaporation, thereby reducing the temperature of the air passing over it, and the sponge or whatever contains it, and limiting its own evaporation, in a greater degree."—'Edinburgh Medical and Surgical Journal,' No. 180.

It is on account of its greater strength that a larger number of accidents have occurred with chloroform than with ether. At the same time, where great care is taken in its administration, there seems to be no reason why chloroform should not be employed for the production of anæsthesia. The usual method of administering this agent is to sprinkle a few drops upon a handkerchief and apply it to the mouth and nostrils of the patient, in such a way that the patient may take air into the lungs which is saturated with the vapour of chloroform. During this operation care should be taken that a larger quantity of the vapour is not inhaled than will produce the fourth stage of anæsthesia. By removing the handkerchief from time to time the patient may be kept in the third or fourth stage, according as it seems desirable. Although the administering of chloroform in the handkerchief is undoubtedly the most simple and convenient plan, it appears to be much safer to use an instrument called an inhaler, by which the quantity administered can be regulated and controlled with certainty. Such an instrument was early introduced and employed by Dr. Snow, and the accidents which have occurred have certainly been fewer when this instrument has been employed than with the handkerchief. In the inhaler employed by Dr. Snow, the compartment containing the chloroform is surrounded with cold water, to limit the quantity taken up by the air, and the expiration valve of the face-piece is so adapted as to admit additional air to any extent to dilute the vapour still further. From an investigation of the fatal cases, and experiments upon animals, Dr. Snow has arrived at the following conclusions:—

1. Chloroform vapour, if it be inhaled in large proportion with atmospheric air, destroys life by paralysing the heart.

2. In smaller proportions, but long continued, it produces death apparently by the brain, and by interfering with the respiratory function. In such cases the heart is found to beat after the respiration has ceased.

3. Chloroform vapour, if it be blown upon the heart, paralyses it immediately.

4. Atmospheric air loaded with from 4 to 5, or even 6 per cent. of chloroform vapour may be safely administered, inasmuch as that mixture will not act directly upon the heart, but will give timely notice of its increasing effects in modifying the normal discharge of the functions of life. The average time occupied in producing insensibility is from three to four minutes.

5. The proportion of as much as from 8 to 10 per cent. of vapour of chloroform to atmospheric air is a dangerous mixture, as it suddenly charges the blood going into the heart with a poison capable of acting directly on that organ.

In cases where an over-dose of chloroform has been administered, the only remedy which appears to offer a chance of relief is artificial respiration. Where the muscles of the tongue become relaxed, and this organ falls back over the glottis, it should be pulled forward till the patient revives. It might be desirable to open the jugular vein in order to relieve the distension of the right cavities of the heart.

The cases in which ether was first employed, and in which chloroform is to be recommended as an anæsthetic, are those in which operations producing pain are performed. There are no operations, from the extraction of a tooth to the capital operations of surgery, in which it may not be employed. At the same time it may always become a question whether it is worth while running the slight hazard of fatal effects for the sake of relieving a small amount of pain. Where chloroform is skilfully administered, there appears to be little or no hazard, but unfortunately it is not every one who is prepared to administer chloroform successfully. As a rule it may be stated, that it is not advisable for the surgeon who operates to administer the chloroform, and a competent assistant should always be employed to do this. Whatever may be the doubt in the minor operations of surgery, the beneficial effect of relieving pain upon the subsequent welfare of the patient in the capital operations of surgery, have led surgeons very generally to insist on its administration in these cases. It has now been shown, both by Dr. Simpson and Dr. Snow, that the fatal cases, after capital operations, more especially amputations, are fewer when chloroform has been administered, than when this or some other anæsthetic has not been employed. Looking to these results, it would appear that the life saved by the use of chloroform has been much greater than that sacrificed by its careless administration. When in addition to this it is recollected how great an amount of suffering is prevented, there can be little doubt about the propriety of its administration.

It has been supposed that certain states of the system are less favourable to the administration of chloroform than others, but Dr. Snow has pointed out that in these states of the system the pain of an operation would be as likely to act as injuriously as the chloroform. At the same time, it would appear that a certain number of the fatal cases have occurred in persons with diseased heart, and perhaps in these caution should be employed.

Besides in operations with the knife, chloroform has been employed to facilitate the reduction of dislocations and of hernia. It has also been recommended in asthma, and as a means of procuring sleep in excessive watchfulness. It was first introduced by Dr. Simpson, of Edinburgh, as a means of alleviating the pain attendant upon child-birth, and although it has been much opposed in these cases, it is at the present day very largely administered by the obstetric practitioners of Great Britain. In some of the more difficult cases it becomes an important aid to the accoucheur, and in all cases it diminishes the suffering without in any way interfering with the natural actions attendant upon this condition. The injurious effects attributed to chloroform are at most problematical, and the benefits so decided as to lead to its use wherever circumstances will permit. At the same time here, as in other cases, it is not desirable that the operator should administer the chloroform, and as the services of an assistant, or person competent to administer cannot always be procured, it is not likely to come into general use throughout the country. But when assistants can be found, there is no doubt that it is an alleviation of suffering that ought not to be discountenanced.

From having experimented with various agents, Dr. Snow was induced to try the action of Amylene as an anæsthetic on the human system. This substance is a colourless mobile fluid, having a specific gravity of 0·659. It is very volatile, and boils at 102°. Its composition is $C^{10} H^{10}$. It is soluble in ten or eleven pints of water, and its odour is not disagreeable. The quantity of amylene required to produce anæsthesia is intermediate between that of chloroform and ether. The quantity of amylene consumed in Dr. Snow's inhaler was at the rate of rather more than a fluid drachm in a minute, and in this way insensibility was produced in about three minutes. Although Dr. Snow successfully administered this remedy in several cases, he met with two fatal cases, and afterwards abandoned its use.

Other substances are capable of producing anæsthesia in the form of vapour, but none of these have been generally employed.

(Snow, *On the Inhalation of the Vapour of Ether*, 1847; *On Narcotism by the Inhalation of Vapours, Medical Gazette*, 1848 to 1851; *On Death from Chloroform, Lancet*, 1856. Pereira, *The Elements of Materia Medica and Therapeutics*, 1853. *On Chloroform and other Anæsthetics*, by Dr. Snow: this work was published in 1858, after the author's death.)

A'NAGRAM signifies a new word formed out of the letters of any given word by the process of writing them over again, as the term literally signifies, or placing them in a new order. Sometimes the anagram is formed out of two or more words, and it may be itself always either one word or several. Some traces of this species of trifling have been detected in the writings of the ancients; but the taste for it does not seem to have spread much among the Greeks or Romans. The artifice appears to have first become fashionable in modern literature in the early part of the sixteenth century. Many authors, instead of putting their names on the title-pages of their works, have, with an affectation of modesty, used the anagrams of their names. At one time also the anagram was made much use of by mathematicians in announcing discoveries, the credit or property of which they wished to secure to themselves without revealing the secret in which they consisted. Huyghens, Galileo, and Newton intimated several of their discoveries in this way.

ANAKIM, or Benei-Anak, the sons of Anak, were a race descended from Ahiman, Sheshai, and Talmai, the three sons of Anak mentioned in Numbers xiii. 22. They inhabited the mountainous parts of southern Canaan, which afterwards formed part of the territory of the tribe of Judah. At the time of the invasion of that country by the Israelites, the Anakim possessed the towns of Anab, Hebron, Debir, and others. They were apparently above the common size of men. The spies sent by Joshua represented them as giants, to whom they were but as grasshoppers; and their mere appearance alarmed them when sent to examine their land. They were, however, eventually conquered by the Israelites under Caleb, and expelled, but a remnant took refuge with the Philistines. The total number could not have been large, as, though described as consisting of three tribes under separate kings, it would appear that all three of the sons were alive at the time of the conquest, and that Ahiman dwelt in Hebron. Sons of Anak, may, however, mean descendants; and in Numbers xiii. 23, the three chiefs are called children of Anak, which may imply a more remote relation than the filial one, as we say children of Israel for the whole race even at the present time. Hebron and Debir, moreover, are the Hebrew names of towns built on the sites of Kerjath-arba and Kirjath-sepher, the proper names of the Anakim towns. Anab has disappeared.

ANALEPTICS, from a Greek verb which signifies to *restore*, comprise all the means, whether medicines, diet, or regimen, which are generally employed to restore the vigour of the system when it has fallen below the healthy standard, either from previous disease or any other cause. The term analeptic was formerly applied indiscriminately to any medicine which increased the powers of the system, whether it belonged to the class of stimulants or to the class of tonics; but as the progress of chemistry, anatomy, and physiology has enabled us to recognise a difference in the chemical composition of members of these two classes of medicinal agents, as well as in their manner of acting upon the human frame, we propose to limit the application of the word to the latter of them, or to tonics, reserving the consideration of the other till we come to the word stimulant. The following brief explanation of their effects will suffice to justify this proceeding. Stimulants act primarily on the nervous system, while tonics act primarily on the muscles and blood-vessels. Stimulants render the movements more frequent; tonics render them stronger. Stimulants, as we see with wine, exhaust the excitability; tonics, within a certain limit, maintain it. The action of the one is immediate and transitory, that of the other is slow and progressive, but more permanent, as is the case from cinchona bark, or food. To take an example from their effects on the stomach, excitants quicken the digestion, as we see with capsicum or cayenne pepper, which we take with articles difficult to digest, as salmon; while tonics render the digestion more perfect, as occurs when we use cinchona in convalescence from disease. Though the most perceptible effect of tonics be upon the muscular system, as it is by a display of its powers that we judge of strength, yet the whole system feels the benefit of them when appropriately administered. Every person knows that he can, at one time, lift a weight with ease which, at another time, he cannot move but with difficulty and exertion. In the former case, he is pronounced *strong*; in the latter, *weak*.

The nature of the muscular fibre need not be discussed here; it is enough for us to remark, that to execute its functions properly, it must be in a certain state of tension, that it may be possessed of sufficient elasticity. A cord proceeding from a fixed point cannot influence a moveable body till it be drawn tight; so a muscle cannot raise a limb unless it possess a certain degree of tightness. The difference of the power of muscles varies greatly, according to the state of health or disease of the individual. If a muscle be taken from an animal in good health, it will not only bear a greater weight than the same muscle taken from an animal which has long been sick, but the former will be many days before it goes to decay and allows the weight to drop, while the latter will decay very speedily.

To maintain the muscular fibres in this condition, a due supply of blood and of nervous energy is requisite. The sources of these are in a healthful and vigorous digestion, and as this rarely goes on when the system is much disordered, or suffering under general or considerable local disease, scarcely any morbid action, or even the natural exercise of mind or body, if pushed to an extreme, can continue without producing debility. Tonics are, sooner or later, required, seldom, indeed, to remove disease, but to obviate its effects, or that of the treatment it has been necessary to employ. The use of these requires the greatest circumspection, for, till we have removed the cause of the disease, they can rarely be of service; on the contrary, they often do harm.

We have above pointed out the connection between the state of the digestive functions and the energy of the other functions, and it is important to bear in mind that anything loading and oppressing the stomach and bowels will lessen the tone of the system, diminish the disposition for exertion, and clog alike the action of mind and body. A judicious practitioner will here give, according to circumstances, an emetic or a purgative, and repeat this last for three or four days successively; in proportion as these act well, the languor and listlessness disappear, the mind resumes its wonted activity, for the cloud which had obscured the mental faculties is dissipated, and all again is energy, elasticity, and strength. An unskilful practitioner, and still more frequently the patient or his friends, would recommend some stimulant, a little brandy, or some bitters, under the influence of which all the symptoms become aggravated. It is a still worse case when the debility which occurs at the commencement of fevers, particularly ague and typhus, is so treated, though this is not so common an occurrence. A state of great irritation (morbid sensibility), or subacute inflammation of the mucous or inner membrane of the stomach, is a frequent condition of that organ with the inhabitants of towns, particularly among merchants and others engaged in extensive business which engrosses their whole attention, giving rise to much anxiety and leaving little time for exercise or food at proper times. The employment here of tonics, in the first instance, will only convert a manageable case into a difficult and serious one. It is, therefore, rather in the stage of convalescence from acute disease that tonics are required, and as a sequence to other medicines, than articles to be employed in the commencement, if we except some affections of the nervous system.

We need not enter into details respecting the particular action of tonics upon each set of organs of the body, as it may be stated generally that they all, sooner or later, begin to execute their functions more vigorously, the stomach first feeling the beneficial effects. But this state of improved action follows their use (that is, when they are medicinal or material tonics) only for a time; for their continued employment leaves the stomach in a state of debility, perhaps greater than at first—a fact of which we should never lose sight. These remarks will, we trust, induce all to observe caution both in taking upon themselves to use the articles termed analeptics merely because they feel weak, without knowing what is the cause of the weakness, or in urging their friends to have recourse to them at the commencement of disease, or even when it is subsiding, as more relapses are occasioned by a premature employment of tonics, whether medicinal or dietetic, than by all other causes combined.

It is impossible to enumerate here, and give directions for the use of, all the analeptics, comprising, as they do, medicines, food, and regimen. The medicines are either from the mineral or vegetable kingdoms; when the former, they are chiefly preparations of the metals, as the salts of iron and flowers of zinc (oxide of zinc); from the latter, they are invariably bitter substances, as cinchona bark, calumba, quassia, chamomile, &c. The analeptic means which fall under the head of regimen are, bathing, exercise, and the diversion of the mind.

The employment of the medicines will be stated under the diseases to which they are suited; bathing will be treated of under that head: it is, therefore, only upon the last two means that we will make any remarks here.

An examination of the human frame demonstrates that it was intended for motion, alternately with repose, and not for a state of absolute quiescence. Nor is the mind, which is furnished with so many faculties and provided with so many organs of sense, which serve to connect it with the external world, less calculated for active exertion. Any attempt to contravene the law of nature which enjoins a reasonable exercise of mind and body, brings a punishment upon the individual; the mind which he allows to be inactive loses the capacity for exertion, when required, and the body becomes a prey to disease in some shape or form. The action of the muscles is necessary to aid in circulating the blood and in completing the process of digestion, as well as to ensure a regular motion of the bowels. Where the muscles are not exercised, the blood, instead of reaching the surface and the extreme vessels, accumulates in the large internal trunks, leaving the skin dry and bloodless, as seen in young chlorotic females, who, instead of appearing buoyant with life in every limb, are as pale, and almost as inanimate, as a statue. Disorders of the nervous system, such as hysteria, likewise show themselves. These states can only be warded off by regular exercise. The rising generation would be much benefitted, if instruction in any branch of natural history formed a part of their education; young persons would then be furnished with motives for taking exercise out of doors—to the manifest advantage of the figure of the body and the tendencies of the mind.

Where older people have neglected exercise, it is more difficult to find means to induce them to resume its use; but some such device as the following may be tried: "Ogul, a voluptuary, who could be managed but with difficulty by his physician, on finding himself extremely ill from indolence and intemperance, requested advice: 'Eat a basilisk stewed in rose-water,' replied the physician. In vain did the slaves search for a *basilisk*, until they met with Zadig, who, approaching Ogul, exclaimed, 'Behold that which thou desirest! But, my lord,' continued he, 'it is not to be eaten; all its virtues must enter through thy pores; I have, therefore, inclosed it in a little ball, blown up, and covered with a fine skin; thou must strike this ball with all thy might, and I must strike it back again, for a considerable time, and by observing this regimen and taking no other drink than rose-water for a few days, thou wilt see and acknowledge the effect of my art.' The first day Ogul was out of breath, and thought he should have died of fatigue; the second he was less fatigued, and slept better: in eight days he recovered all his strength; Zadig then said to him, 'There is no such thing in nature as a basilisk! but *thou hast taken exercise and been temperate, and hast, therefore, recovered thy health!*'"

The Indian-rubber, or caoutchouc balls, will be found as useful for those confined by the weather within doors during the winter months, as the ball of Zadig.

It is possible to fatigue the body beyond a proper point, in which case repose becomes necessary; but this is a rare occurrence compared with the instances where the mind is stretched beyond its natural power to bear by the ambitious student, the covetous and care-worn merchant, or the adventurer in political life. If, in consequence of long-continued exertion, the balance of the mind be not already lost, abstraction from his books for the one, and a withdrawing from their pursuits for the others, with change of scene and occupation, must be enjoined; by doing this before it is too late, each may, in time, return to his usual station, to be useful in his sphere to himself and others, and may still be permitted to enjoy the greatest of earthly blessings,—a sound mind in a healthy body.

ANALOGY is the similarity of ratios or relations. A *ratio*, or *relation*, means that two objects (which are called *the terms of the ratio*) are considered together in reference either to some quality which they have in common, or to some manner in which one has affected the other.

Thus, two things may stand in a certain relation to each other, in respect of their quantity, magnitude, shape, colour, strength, height, &c.; in which cases the subject of comparison is common to both, and belongs to them to a greater or less amount. Thus, when we say that one thing is larger, taller, thicker, smaller, darker, more beautiful, more lasting, more desirable, more formidable, more probable, &c., than another, we mean that each of the pairs in question having in common the quality referred to, the former has it in a greater degree than the latter. These, which might be called *ratios of degree*, differ altogether from the other class, which includes all those relations arising from the manner in which one term of the ratio has affected the other, or is necessarily connected with it, and not from any attribute which they possess in common. Thus, we may speak of the relation of God and man, of the relations of men as members of the same political society or of different political societies, of the relation of a bird to its egg, of a tree to its fruit, &c., in which instances some act done by one to the other party, or by both reciprocally, or some influence which one term has exercised over the other, is signified, and not any quality or attribute common to both. In some cases of the latter kind there are words which express each term of the ratio *in respect of the relation*; and, therefore, they mutually imply each other. Such are, for example, parent and child, debtor and creditor, agent and principal, lessor and lessee, &c. As in these cases it is impossible to conceive the one without conceiving the other term, the latter might be called *ratios of implication*, as distinguished from those ratios in which a comparison is made of qualities existing independently in the things compared. For example, there cannot be a husband without a wife, or subjects without a sovereign, nor is there any quality which a husband has, as husband, independent of the wife, or the sovereign as sovereign, independent of the subject; but although there cannot be a short man or a tall man without a man of middle size, yet the height of the short or tall man is an absolute quantity, and independent of the comparison. In the cases of a common property, or ratios *of degree*, there are words which denote the *relation* of one term to the other, as lowness, height, depth, and consequently imply both terms of the ratio; but there is no word which expresses the *term* of the ratio itself, as in the case of ratios of *implication*. (Locke 'On the Understanding,' ii. 25.) There are some words used to denote the state of one of the terms of a ratio of implication when the relation has been destroyed; thus, *widow* means an unmarried woman who was once a wife; *orphan*, a child whose father is dead, &c. Sometimes the terms denoting a relation are applied by anticipation before the ratio begins to exist; thus, a person is popularly called an heir in the ancestor's lifetime although *nemo est heres viventis*.

When two ratios are compared, that is, when it is affirmed that the relation of two things is like the relation of two other things, the two ratios together form an *analogy*, and each pair of the corresponding terms of the two ratios is *analogous*. Thus, the bark stands in a similar relation to a tree as the skin to an animal; and consequently the one bears an analogy to the other: so the feathers of a bird are analogous to the hair of a quadruped, the admiral of a fleet is analogous to the general of an army. Of this nature are all fables and parables, in which the circumstances of the person to whom the lesson is addressed are illustrated by a parallel case, that is, by supposing a relation similar to that in which he is placed. Thus the case of a man who affects to despise what is out of his reach is vividly pourtrayed by the fable of the 'Fox and the Grapes;' and so in other cases, the parables of Holy Writ are instances of a similar mode of instruction, only the examples are not, as in fables, chosen among irrational animals. The same is the principle of grammatical and etymological analogy; thus, if *to give* is conjugated *I give, thou givest, he gives, to live* would be conjugated *I live, thou livest, he lives*; the inflexions of the verbs standing in a like relation to each. So the verb *prattle* is derived from *to prate*, as *hobble* is from *to hop*; *little* is derived from the old word *lite*, as *mychel* or *myckle* from *much*, &c. Thus, *kingly* is to *king*, as *royal* to the French *roy*, and *regal* to the Latin *rex*, or rather to the root *reg*. The formation and development of language proceed almost exclusively on this principle.

From what has been said it is evident, 1, that in an analogy there must be two ratios, and consequently four terms or objects of comparison; and 2, that there is no connection between resemblance and analogy, and that things may be analogous without being similar, and similar without being analogous.

1. With regard to the first of these propositions, it should however be observed, that, although there must be four terms, it is not necessary that all the four terms should be different. If there was such a necessity, one of the chief uses of analogy, as an engine of argument and discovery of truth, would be destroyed. All that is required is, that there should be two distinct ratios: of what terms those ratios may consist is indifferent. Thus in the case of brethren, the parents are in an analogous situation in respect of each brother: so the grandfather is to the son, as the son is to the grandson. In such cases as these, both the relations are known: frequently, however, the relation in which one thing stands to another being known enables us to discover, with greater or less certainty, the relation which the same thing bears to something else, which is unknown. Thus the moral government of mankind by the Deity, in this world, furnishes a means of conjecturing his religious government, both in this world and the next, independently of Divine revelation. So the past conduct or performances of a nation, a government, a minister, a general, a lawyer an architect, a painter, a poet, a racehorse, &c., afford materials for judging what will be their future conduct or performances under similar circumstances. It is to this most important use of analogy that Quintilian refers, when he says that its purpose is to discover what is unknown by what is known, to prove what is uncertain by what is certain.

2. Resemblance being the similarity of some sensible quality, as form, colour, taste, smell, or sound, it has evidently no connection with analogy; and if things analogous happen to resemble one another, their resemblance is a mere accident, independent of their analogy. Thus, two brothers may resemble each other; but they might equally resemble each other without being brothers, and would be equally brothers if they did not resemble each other. The confusion of analogy and resemblance is however of very frequent occurrence, and numerous examples of it might be cited. When Homer says that Apollo and Minerva sat, like birds, on the branches of a tree near the Scæan gate of Troy, he meant, as birds sit on the branches, so did the god and goddess: but Pope, and other translators, represent them as undergoing a change of form, and assuming the appearance of birds.

The above example may serve to illustrate an error of frequent occurrence in the use of the argument from analogy. As, in the instance just cited, the similitude is extended beyond its proper limits, and it is supposed that because the two objects are like each other in *one* respect, they are like in *all*; so the analogy between two things is sometimes pressed beyond its just application, and is carried out of the bounds of the relation in virtue of which the comparison was made. Thus the injunction to be "as wise as serpents and harmless as doves," does not recommend to our imitation either the envenomed ferocity of the one animal, or the helpless timidity of the other. Two false analogies may be mentioned which at one time had a powerful influence on political discussions, nor are even now quite exploded, namely, that the existence of the human race, and the existence of nations, are analogous to the life of a single man. For some purposes these two relations might doubtless be compared; but when it is argued that a nation will pass through a series of changes corresponding to the childhood, manhood, and old age of a single human being, or that the early state of mankind was like the innocence and simplicity of an infant, the comparison is unwarrantably wrested out of the range of its proper application. The notion of the corruption of a nation by luxury appears to have had a like origin; for single individuals may be, and often are, depraved by a sudden change from poverty to riches; but the process by which a nation enriches itself, is a mark of habits very different from vicious indulgence and effeminate indolence.

All analogical comparisons are made by means of abstraction. A certain attribute belonging to each of two objects is considered separately from all the other attributes which those objects may possess, and a comparison is instituted between them in respect of that common attribute. Thus, the analogy between the skin of an animal and the bark of a tree arises from our leaving out of our consideration all those circumstances in which they differ, such as their colour, consistency, animation, sensibility, &c., and paying attention only to the use of each, as the outward covering, in one case, of the body and limbs of the organised being, and in the other as the outward covering of the woody matter of the tree. It is by a like process of abstraction that an extended and vague meaning is given to many general terms, particularly those belonging to the moral sciences; and in this manner they are applied to objects to which they are only analogous, and which they do not properly designate. Thus a law, in its original and strict sense, is a general command of one rational being to another: but as one of the effects of such a command is to produce a uniformity of conduct in the person or persons to whom the command is addressed, the word has been transferred to inanimate objects in which there is a uniformity of phenomena; and although there is no command received, no command given, and no intelligence to work upon, we yet speak of the laws which regulate the motion of matter, the succession of the seasons, the diffusion of heat and light, and other physical appearances which follow in a constant relation of cause to effect. In this case the proper characteristics of a law being neglected, one of its relations is alone considered; and hence the analogical application just mentioned. When such an application is made, not from a vague or inaccurate use of language, but from a desire to add beauty or energy to the expression by the transfer of words, this transfer and sometimes the transferred word itself, is called a *metaphor*. Thus, when Shakspere represents Macbeth as saying of Duncan that

> "His virtues
> Will plead like angels, *trumpet-tongued*, against
> The deep damnation of his taking off,"

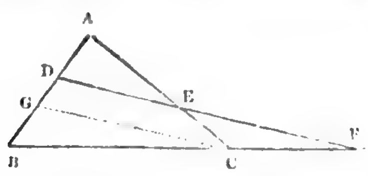
he means that Duncan's virtues will arrest the public attention as forcibly as the sound of trumpets. The analogy is obtained by referring the two objects compared to the general class of things which instantly attract universal notice.

The word *proportion* properly signifies an analogy of quantities or magnitudes, as a proportion of numbers, lines, surfaces, &c. In popular usage however proportion is commonly made synonymous with *ratio*, as when we speak of the proportion of deaths to births, the proportion of wages to profits, the proportion of convictions to commitments, &c. Sometimes also it is used for *portion*, as when we speak of a large proportion, a small proportion, a fair proportion; in this case however, a ratio is meant, as the part is considered as bearing a certain relation to the whole.

(On the subject of Analogy see Aristotle's *Poetic*, c. 21; *Rhetoric*, b. ii. c. 2; *Hist. An.* i. c. 1; Coplestone in the Appendix to *Whately's Rhetoric;* Whately's *Rhet.*, part i, c. 2, s. 6; Mill's *System of Logic*, cap. iii. s. 12.)

ANA'LYSIS, a Greek word, signifying literally *the act of unloosing* or *untying;* its opposite is *synthesis*, which is the act of putting together. The modern meaning of the term analysis is the process by which facts, results, or reasonings are separated into their simple and component parts, or by means of which a simple truth is obtained when given in a more complicated form; so that, in its most general sense, the greatest part of human knowledge consists in the results of analysis. It is, however, for the most part applied in a more particular manner to the methods employed in those branches of inquiry, which most strikingly exhibit direct analysis; namely, mathematics and natural philosophy, particularly chemistry. By a very incorrect misnomer, algebra, the differential calculus, &c., have been called by the general name of *analysis*, in opposition, not to *synthesis*, but to *geometry*, in which latter science synthetical methods are most usually applied. This perversion of the term prevails on the Continent to such an extent, that it must always be taken for granted, that '*analyse*' stands for the algebraical branches of pure mathematics. In this sense it is again subdivided into 'algebraical analysis' and 'infinitesimal analysis,' the latter including the fluxional or differential calculus. And by 'geometrical analysis' is frequently understood the application of algebra to geometry. It must, however, be remarked, that the exact sciences have appropriated this word, simply because in these branches of knowledge the use of analysis has been made most conspicuous.

Confining ourselves to the primitive meaning of the term, it is obvious that all discovery must be entirely either the work of analysis or of accident; and that, therefore, geometrical analysis must be as old as geometry. Nevertheless, this does not appear from the earliest treatises. The work of Euclid is strictly synthetical. Instead of taking the proposition asserted, and examining it by means of preceding propositions, and in the mean time assuming it to be true, in order to ascertain whether the results deduced from it agree or disagree with what has been already proved,—Euclid first enunciates the point which he means to establish, and then proceeds to put together the considerations by which it is demonstrated, leaving the learner nothing to do but to judge of the truth or falsehood of each argument as it arises, without taking into consideration the methods by which the arguments themselves were first obtained. This is the natural and proper method of teaching what has already been discovered, for its own sake; not only because it neglects to introduce difficult and embarrassing considerations, and allows of the subject being broken up into portions which are easily learnt at one time, but because there is, in reality, no perfectly general and certain method of analysis which can be made obvious to the beginner. In attempting the analysis of a new problem, though the discoverer will naturally first try those methods which have been successful in preceding cases, he has no means of assuring himself beforehand which will be successful. The chemist is similarly circumstanced. Let a new substance, or one supposed to be such, be presented to him, from which he is required to find out whether it is already known, or if not, of what it is composed. No effective analysis can commence without requiring the results of all his previous knowledge; for he must have some method of recognising each and every substance with which he is acquainted, previously to pronouncing whether or not that under consideration is one of them. He must then proceed to trials of that substance with various others, and nothing but the sagacity which arises from previous experience can direct him in his choice of the methods to be employed. No general rules of analysis can be laid down: that is, no processes which must end in the discovery of the component parts required. The same observations may be made on mathematical analysis. We give a geometrical instance, with its result, and the synthetical form of the proposition arising out of it.



The sides of a triangle ABC are cut in D, E, and F, by a straight line. Six segments are thus formed, AD and DB, whose sum is the side AB; AE and EC, whose sum is the side AC; and BF and FC, whose difference is the side BC. It is required to investigate the relation which exists between these six segments, if there be any relation.

Some relations will be thrown out of the question upon the slightest consideration: the sum of the six lines is not the same in every triangle, neither is their product. Leaving this unorganised method of examination, we recollect, that if CB were parallel to DE, the then similar triangles ADE, ABC, would give a well-known relation between AD, DB, AE, and EC. To try whether this may help us, draw CG parallel to DE, which gives the proportion

$$AD : DG :: AE : EC,$$

or if we represent the lines by the number of units which they contain,

$$AD \times EC = AE \times DG \quad . \quad . \quad (1.)$$

Because GC is parallel to DF, we have

$$GD : BD :: CF : BF,$$

$$\text{or } GD \times BF = BD \times CF \quad . \quad . \quad (2.)$$

and the equations (1.) and (2.) multiplied together, and the result divided by the common factor GD, gives

$$AD \times EC \times BF = AE \times BD \times CF \quad . \quad . \quad (3.)$$

whence the relation required between the six lines is as follows: Let them be separated into two lots of three lines each, in such a way that no two lines which have a common extremity are both in the same lot; then the product of the first three will be equal to the product of the second three.

If instead of asking for the relation, if any exist, between the six lines, the equation (3.) had been given, and it had been required to detect whether it were true or false, the process would have been similar; and we should have found that the equation (3.) is true, and a necessary consequence of the proposition, that a line drawn parallel to one side of a triangle divides the other sides into proportional segments.

The synthetical form of the preceding process differs from it much less on the paper than would be the case in the mind of a student, who had actually hit upon the solution in the progress of investigation. For, not being able to tell the various steps by which one of our readers would endeavour to arrive at the same conclusion, we are obliged to prompt him with a right guess, and thereby give him only a synthetical description of that which was in our minds an analytical process. It only remains, therefore, to make the demonstration synthetical in form, which, as will now be readily seen, will consist in stating the proposition to be proved, directing to draw CG parallel to DF, without giving any reason, and combining the steps of the preceding demonstration.

The geometrical analysis is generally ascribed to the school of Plato; but, in reality, as we have already observed, must be of a date as early as geometrical reasoning itself. The use of PORISMS, or problems [see also LOCI] admitting an indefinite number of solutions, the establishment of the properties of the CONIC SECTIONS, and the various efforts made for the DUPLICATION of the cube and the TRISECTION of the angle, all of which were the work of the school already mentioned, most certainly increased the power of the analyst, that is, made the means of discovery more obvious and more successful; but there is nothing in the methods which entitles them to the exclusive appellation of geometrical analysis.

The peculiar distinction between algebra and geometry is, that the analytical method is pursued in the former from the commencement. The solution of a problem consists in inquiring into the consequences of the solution *supposed to be found*, by introducing at every step some known truth, such as will produce a more simple consequence, and thus reasoning backwards, so to speak, until at last the answer itself is directly produced in numbers, which was before implicitly involved in the conditions of the problem. The methods are more general than in geometry, that is, a larger number of problems may be solved by each process. The same observations apply still more strongly to the higher parts of algebra, and the differential calculus.

The solution of equations of the first four degrees, and the approximation to that of all higher degrees, render the analytical solution of a vast number of common problems a matter of certainty. The solution of differential equations, where that can be done, is an additional step of even a more important character. Within the last century, mathematical analysis has made considerable approaches to a state which enables us to determine, almost immediately, whether a problem can be solved by such means as we possess, or not; no small advantage, when it is considered how much time was previously wasted in the attempt to attain results which have since been shown to be impossible.

ANALYSIS, CHEMICAL. [CHEMICAL ANALYSIS.]

ANALYSIS, EUDIOMETRIC. [GASOMETRIC ANALYSIS.]

ANAMERTA or ANAMIRTA, the name of a genus of plants belonging to the natural order *Menispermaceæ*, to which the plant yielding the Cocculus Indicus of commerce is now referred. It has the following characters: flowers diœcious, calyx of six sepals in a double series with two-close pressed bracteoles, corolla none; stamens on separate flowers united into a central column, dilated at the apex; anthers numerous, covering the whole globose apex of the column. The flowers with pistils are not known, but the fruit is a one- to three-celled drupe. The seed is globose, deeply excavated at the hilum, albumen fleshy, cotyledon very thin, diverging. The plant which yields the berries of commerce is the only species of this genus. It is a strong climbing shrub, and is met with on the coasts of Malabar and the Eastern Islands. It is called *Anamirta Cocculus;* it possesses a powerful bitter poisonous principle, and is used for external applications only.

ANAMIRTIC ACID. ($C_{35}H_{33}O_4$?) Obtained from the seeds of *Anamirta Cocculus*, but now believed to be identical with stearic acid. [STEARIC ACID.]

ANAMIRTIN ($C_{36}H_{24}O_4$.) A white crystalline body obtained by Francis from the seeds of the *Anamirta Cocculus*. When saponified by potash it is said to yield anamirtic acid.

ANAMORPHO'SIS (ἀνάμόρφωσις, a 'remodelling or change of form'), is such a representation of an object that, except when viewed from a particular point directly, or in a cylindrical mirror, or through a polyhedral lens, it will appear to be distorted, or disconnected, or to be a view of something very different from the original object. Such representations are only made for the amusement of young persons, and therefore a very brief explanation of them may suffice; but the art of forming them has been treated at length in the 'Thaumaturgus Opticus' of Niceron, and in the 'Perspectiva Horaria' of Maignan.

Distorted figures which are to appear, when viewed directly from a given point, in the just proportions which they have in an original drawing or print, may be easily traced in the following manner. Let the original be covered with a network of squares, and imagine it to stand vertically on paper laid on a table, the eye being in a given position in its front; then draw lines through the ground line, in the directions in which planes passing through the eye and the vertical lines drawn on in the original would cut the paper, and other lines parallel to the ground line at places where planes passing through the eye and the horizontal lines on the original would cut the paper. If within the trapezoidal areas thus formed the parts of the original figure which fall in the corresponding squares be drawn, the figure thus traced will be the distorted figure required; and, when viewed from the assumed place of the eye, it will evidently appear exactly as, to an eye in the same point, the original would appear if it were placed in a vertical position with the base on the line which was drawn to represent it; that is, it will appear to be an exact copy of the original.

A distorted representation of some object, which is to appear correct on being viewed from a given point, and by reflection from a cylindrical mirror whose curvature and position are also given, may be drawn on a plane by means of a perspective representation, as already described, or the squares drawn within a square circumscribing the original print or drawing. Thus a circular arc being drawn with a radius equal to that of the base of the cylinder, to intersect, between the eye and the ground line, all the oblique lines drawn in forming that representation; let lines be drawn from the intersections, making respectively equal angles with tangents to the circle, so as to represent the reflections of those oblique lines; and on the reflected lines set distances from the circumference equal to the distances of the parallel lines in the former representation from the same points in the circumference. Then curve lines connecting the points so determined will form, with the reflected lines, spaces within which the parts of the original figure are to be traced so as to correspond to those within the squares first drawn. This distorted tracing being laid horizontally on a table, and the mirror being set up vertically on the arc which represents its base, the reflected image will, to the eye, appear exactly similar to the original figure.

Distorted figures, which are to be seen corrected when viewed through a polyhedral lens or multiplying glass, may be traced mechanically thus:—let the multiplying glass be placed in a tube, like the eye-piece of a telescope, at a distance from the end to which the eye is to be applied rather greater than the focal length of the glass, and let a very small aperture be formed in the cover at that end: then, on placing a lamp or candle before the aperture, the rays of light passing through the faces of the lens will project, on a screen placed perpendicularly to its axis, at any convenient distance beyond the focus, a number of luminous spaces corresponding to the several faces of the lens, with intervals between them. In these luminous spaces, whose outlines should be traced with pencil before the light is removed, there must be drawn by hand parts of a landscape or figure, so that, on looking through the aperture, they shall seem to form a correct representation of the intended object.

The portions thus drawn, when viewed in any manner except through the aperture, will be unconnected; and the intervals may be filled up with any objects at pleasure, so that the whole may appear confused, or may represent something different from the original landscape or figure: then, on looking through the aperture, towards the screen, the intervals before mentioned, and the objects drawn on them, will be invisible; and there will appear only the representation of the object formed by the junction of the parts within the outlines first traced, that is, a correct copy of the original object.

ANAPÆST, a foot in Greek and Latin metre, consisting of two short syllables followed by a long. It was sometimes called Antidactylus, as being the opposite of the dactyle, which consists of a long syllable followed by two short. Assuming accent in English to be the same thing with quantity in Greek and Latin, the word *témporal* would be an example of a dactyle, and the word *superádd* of an anapæst. From the tendency of English enunciation to carry back the accent towards the beginning of polysyllables, there are not many single words which make anapæsts in our language. But the foot frequently results from the union of two or more words: as in *Dŏ yoŭ heār, Lĕt ălōne;* and sometimes it is found in part of a single word; as, for instance, in the three middle syllables of the word *anticipātion*. The predominance of dactyles in English, and of anapæsts in French, forms one of the most marked distinctions between the musical character of the one language, and that of the other.

ANAPÆSTIC VERSE, a species of verse composed of a succession of anapæsts. Among the Greeks the anapæstic verse was freely used both in tragedy and comedy. Some forms of it occur very often in Aristophanes. Both in tragedy and comedy, the anapæstic verse admits also dactyles and spondees. In English, only poems of the lighter sort have been usually written in anapæstic verse. Anstey's 'New Bath Guide' may be quoted as a well-known example. The line is often reduced to eleven syllables, by the retrenchment of the first, or the substitution at the beginning of an iambus instead of the anapæst. Thus, in the following lines from the work thus mentioned:

> "For I'm told the discourses of persons refin'd
> Are better than books for improving the mind;
> But a great deal of judgment's requir'd in the skimming
> The polite conversation of sensible women"

it will be observed, that the first foot of the second line consists only of one short or unaccented syllable followed by a long; and a similar retrenchment might be made of the commencing syllable of any of the others, without spoiling its prosody.

ANARCHY properly means the entire absence of political government; the condition of a society or collection of human beings inhabiting the same country, who are not subject to a common sovereign. Every society of persons living in a *state of nature* (as it is termed) is in a state of anarchy; whether that state of nature should exist in a society which has never known political rule, as a horde of savages, or should arise in a political society in consequence of resistance on the part of the subjects to the sovereign, by which the person or persons in whom the sovereignty is lodged are forcibly deprived of that power. Such intervals are commonly of short duration; but after most revolutions, by which a violent change of government has been effected, there has been a short period during which there was no person or body of persons who exercised the executive or legislative sovereignty, —that is to say, a period of anarchy.

Anarchy is sometimes used in a transferred or improper sense to signify the condition of a political society, in which, according to the writer or speaker, there has been an undue remissness or supineness of the sovereign, and especially of those who wield the executive sovereignty. In the former sense, anarchy means the state of a society in which there is *no* political government; in its second sense, it means the state of a political society in which there has been a *deficient* exercise of the sovereign power. As an insufficiency of government is likely to lead to no government at all, the term anarchy has, by a common exaggeration, been used to signify the small degree, where it properly means the entire absence. [SOVEREIGNTY.]

ANASTATIC PRINTING. In the year 1841, the proprietors of the 'Athenæum' received from a correspondent at Berlin a reprint of four pages of a number of that journal which had been published in London a few weeks earlier. The copy was so perfect a fac-simile, that had it not come to hand under peculiar circumstances, it would have been taken for two leaves out of a sheet actually printed in London; the observable difference was, that the impression was somewhat lighter, and the body of ink less in quantity than usual. In reply to further inquiries, the correspondent at Berlin could only discover that the secret was said to be in the hands of a person at Erfurt. He had seen a fac-simile of an Arabic MS. of the 13th century; and another fac-simile of a leaf of a book printed in 1483—both such close copies as hardly to be detected from the originals, and both taken without injury to the originals. It was also stated that a prospectus was issued at Berlin, of a pirated edition of the 'Athenæum, to be produced in a similar way, and sold at a low price.

In January 1845, the 'Athenæum' was enabled to announce that the inventor or discoverer of the method was a M. Baldermus, who had communicated the discovery to a person in London; and to convince the proprietors of that journal of the reality of the method, a page of 'L'Illustration,' French journal, was faithfully copied in a quarter of an hour. The method became known by the name of *Anastatic printing;* and many of the London journals directed attention to the subject. In the 'Art Union,' for February, 1845, pages 40 and 41 of the number were printed from zinc plates obtained by the Anastatic process. The compositors 'set-up' in the usual way, sufficient matter to fill two quarto pages of the work, leaving spaces for three wood-cuts, three drawings, and a few lines of writing in pen and ink, which were properly adjusted to the blanks left for them. All were alike copied or transferred to the zinc plates, and then printed from—several thousand copies being taken. The impressions were fainter and less distinct than those from the original types, but were unquestionably remarkable.

Professor Faraday explained the rationale of the Anastatic process in 1845, at the Royal Institution. The process depends on a few known properties of the articles employed. 1st. Water attracts water; oil attracts oil; but each repels the other. 2nd. Metals are much more easily wetted with oil than with water; but they will readily be moistened by a weak solution of gum. 3rd. The power of wetting metals with water is greatly increased by the addition of phosphatic acid. 4th. A part of the ink of any newly-printed book can be readily transferred by pressure to any smooth surface beneath; if, for example, a corner of a newspaper be fixed on a white sheet of paper, and then pressed or rubbed with a paper knife, the letters will be distinctly seen in reverse on the paper; and indeed every one knows that if a book be bound too soon after the printing, the pages become disfigured by the *setting off* or transfer of the ink upon the opposite pages. From these data the rules for the process are derived. The printed paper, whether letter-press or engraving, is first moistened with dilute acid, and then pressed with considerable force by a roller on a perfectly clean surface of zinc; by which means every part of the sheet of paper is brought into contact with the plate of zinc. The acid, with which the unprinted part of the paper is saturated, *etches* the metal, while the printed portion *sets off* on it, so that the zinc surface presents a reverse copy of the work. The zinc plate, thus prepared, is washed with a weak solution of gum in weak phosphatic acid; this liquid is attracted by the etched surface, which it freely wets, while it is repelled by the oil of the ink in which the writing or drawing on the plate is traced. A leathern roller, covered with ink, is then passed over the plate, when a converse effect ensues; the repulsion between the oil, ink, and watery surface over which the roller passes, prevents any soiling of the unfigured parts of the zinc plate; while the attraction between oil and oil causes the ink to be distributed over the printed portions. In this condition the anastatic plate is complete, and impressions are pulled from it by the common lithographic process. When it is required to apply the anastatic process to very old originals, which do not set off their ink on pressure, the page or print is first soaked in a solution of potash, and then in a solution of tartaric acid: by which is produced a perfect diffusion of minute crystals of bi-tartrate of potash through the texture of the unprinted part of the paper. As this salt resists oil, the ink-roller may now be passed over the surface without transferring any of its contents, except to the printed parts. The tartrate is then washed out of the paper, and the operation is proceeded with as before, commencing with the moistening by nitric acid.

When these interesting details became publicly known, it was soon ascertained that the so-called anastatic printing was little more than an extension of processes known long before in England. Mr. Jobbins, a lithographic printer, took copies of printed pages by a process analogous to that of anastatic printing, as far back as the year 1840. Mr. Cocks, of Falmouth, writing to the 'Mechanics Magazine,' said, "In the year 1836 I introduced a process for the transferring of copper-plate engravings (by the old masters), as well as letter-press printing, &c., to stone, zinc, tin, pewter, type-metal, fusible-metal, lead, copper, glass, &c., and had impressions taken from each; but the original subjects were destroyed by the chemical agents used. Since that time I have succeeded in transferring prints and letter-press without even soiling the originals, fixing the same on metal, wood, or paper, and printing from the form any number of copies. The process is so faithful in its operation, that the finest line of the etching needle is preserved."

In 1848 Mr. Strickland and Mr. Delamotte instituted experiments with a view to ascertain how far the anastatic process would be available as a substitute for lithography. They succeeded in transferring or printing from drawings made on paper with lithographic chalk; within an hour after the drawing was made, a perfect anastatic *facsimile* was produced, hardly to be distinguished from it. The chief difficulty here seems to be the production of a kind of paper which shall possess a surface similar to lithographic stone. A mode has been devised of imparting to India paper a clear sharp granular surface, well fitted for the purpose as far as regards surface; but it is almost too tender in substance. Mr. Strickland found that *metallic paper*, used for metallic pencils, had the required surface. For fine subjects copied in this way, it is essential that the lithographic chalk be of a hard quality, and cut to a fine point.

In 1853, a particular application of lithography was introduced into England from Germany, where it had been patented by M. Sigl. It was a process of machine-printing in lithography, for cheap commercial purposes rather than for matters of fine art. In preparing the plates, a mode of transfer was adopted somewhat analogous to that of anastatic printing. A reference to LITHOGRAPHY will, indeed, show that this analogy extends much farther.

An officer of the United States Survey department, devised a mode of transfer, nearly allied in character to the above, for the printing of maps and charts. An impression from an engraved copper-plate is taken with ordinary ink, on a peculiar kind of paper coated with a fatty substance; and it is then transferred to a lithographic stone, which can be prepared and used in the customary way.

Soon after the introduction of the anastatic process, much alarm was expressed in the commercial world lest it should facilitate the forgery of bank-notes, bank post-bills, cheques, bills of exchange, and other monetary documents. The uneasiness appeared to be not wholly groundless; but the interval between 1841 and 1859 has passed over without any serious realisation of the fears entertained. The transfer of impression is remarkable; but it could not escape the keen scrutiny of persons accustomed to watch for fraud in written or printed documents.

ANASTOM'OSIS, from ἀνὰ, *through*, and στόμα, *a mouth*, signifies the communication of blood-vessels with each other by the opening of the one into the other. The blood-vessels are the tubes by which the different parts of the body are supplied with nourishment. If the blood-vessels destined to nourish a part be obstructed so that it cannot receive a due supply of blood, that part must necessarily die, or, as it is technically termed, mortify. But the blood-vessels are soft compressible tubes, liable, by innumerable circumstances, to have their sides brought so closely into contact as to prevent the flow of a single particle of blood through them. In order to prevent the consequences that would result to the system from the operation of causes thus tending to impede the circulation, provision is made for the freest possible communication between the main trunks of the blood-vessels and their branches, and between one branch and another. All the arteries of the body spring from one great trunk (AORTA) which issues from the heart, and which passes from the heart through the chest, into the abdomen, where it divides into large branches which supply the lower extremities. In this course this vessel gives off innumerable branches, which supply different parts of the body, and these branches form innumerable unions with other branches which proceed from the main trunk of the artery. All the branches which form such communications are called *anastomosing* branches, and this union of branch with branch is termed *anastomosis*. Now so numerous are these anastomosing branches, and so competent are they to carry on the circulation, that if the main trunk of the aorta be tied in the abdomen, or even in the chest, the lower extremities will receive a sufficient supply of blood to maintain their vitality through these collateral or anastomosing branches. The knowledge of this fact enables the modern surgeon to perform with ease and safety operations which the surgeon of former times would have pronounced impossible. Anastomosis is of two kinds, that between large trunks, and that between small branches. When the communication is direct between two large trunks, there is no difficulty in conceiving that the circulation may readily go on though one of the trunks be obstructed, because the trunk which remains open may transmit a sufficient quantity of blood to nourish the part to which it is destined. But when a limb is supplied by one large artery only, and when that is obstructed, how does the limb receive a sufficient quantity of blood to support it? Suppose there is an obstacle to the free passage of the blood through its usual channel, namely, the main artery of the limb. What is the consequence?—the blood is driven in greater quantity, and with greater force into those branches which spring from the main artery above the seat of the obstruction. These branches, in consequence of receiving a greater influx of blood than usual, gradually enlarge in diameter, and transmit through them a proportionally larger quantity of blood. At the same time, the more minute branches, which anastomose with the branches given off below the obstruction, are in like manner dilated and admit a correspondingly free passage of blood to the inferior part of the limb. At first the circulation is in this manner carried on through a congeries of minute anastomising arteries, but in a short time a few of these channels become more enlarged than the rest: as these increase in size, the smaller vessels gradually collapse, and thus ultimately a few large communications constitute permanent channels through which the blood is transmitted to the parts which it is destined to supply. Such is the beautiful provision established in every part of the body to secure to it a due supply of blood, if any obstacle should obstruct the course of this vital fluid through its accustomed channel.

ANA'THEMA, a Greek word, properly signifying, a thing set apart and devoted. Among the Greeks a piece of armour or anything else which was offered to the gods, and placed in a temple, was called an ἀνάθημα (*anathēma*), or offering. Tripods, votive tablets with inscriptions, such as may be seen in the Elgin collection of the British Museum, belong to the class of *anathēmata*. But the dedication or setting apart might be to the powers of evil as well as to those of good, or, according to Pagan notions, to the infernal as well as to the celestial gods. Hence the word came, in one of its applications, to signify much the same thing with the word accursed. It is thus that it is principally used in the Old and New Testaments, where it appears, in 1 Corinthians xvi. 22, with the added form of the original maran-atha, said to mean in Syriac, 'the Lord will come,' and is supposed to allude to the third and principal excommunication among the Jews. In this sense the form *anáthema* (ἀνάθεμα) was employed, and not *anathēma*, though both are really the same word. In the decrees of popes and councils, also, a common form of expression is, whosoever shall do, or not do, or believe, or not believe, a particular act or dogma, 'let him be anathema,' that is, let him be held excommunicated, separated from the society of the faithful, and branded with the curse of the church. On the other hand, a heretic, when he renounced his errors and was received into the bosom of the church, was accustomed to declare his heresy 'anathema,' or a thing accursed. In English we more frequently use the term anathema in the sense of the curse or severe denunciation itself than for the object of the curse; as when we speak of the church directing its anathema against any particular opinion.

ANATOMY ACT. Before the passing of 2 & 3 Will. IV. c. 75, on the 1st of August, 1832, the medical profession was placed in a situation both anomalous and discreditable to the intelligence of the country. The law rendered it illegal for the medical practitioner or teacher of anatomy to possess any human body for the purposes of dissection, save that of murderers executed pursuant to the sentence of a court of justice, whilst it made him liable to punishment for ignorance of his profession; and while the charters of the medical colleges enforced the duty of teaching anatomy by dissection, the law rendered such a course impracticable. But as the interests of society require anatomy to be taught, the laws were violated, and a new class of offenders and new crimes sprung up as a consequence of legislation being inconsistent with social wants. By making anatomical dissection part of the penalty for crime, the strong prejudices which existed respecting dissection were magnified tenfold. This custom existed in England for about three centuries, having commenced early in the 16th century, when it was ordered that the bodies of four criminals should be assigned annually to the corporation of barber-surgeons. The 2 & 3 Will. IV. c. 75, repealed § 4, 9 Geo. IV. c. 31, which empowered the court, when it saw fit, to direct the body of a person convicted of murder to be dissected after execution. Bodies are now obtained for anatomical purposes under the following regulations, enacted in 2 & 3 Will. IV. c. 75, which is entitled 'An Act for regulating Schools of Anatomy.' The preamble of this Act recites that the legal supply of human bodies for anatomical examinations was insufficient, and that in order further to supply human bodies for such purposes various crimes were committed, and lately murder, for the sole object of selling the bodies of the persons so murdered. The Act then empowers the principal secretary of state, and the chief secretary for Ireland, to grant a licence to practise anatomy to any member or fellow of any college of physicians or surgeons, or to any graduate or licentiate in medicine, or to any person lawfully qualified to practise medicine, or to any professor or teacher of anatomy, medicine, or surgery; or to any student attending any school of anatomy, on application countersigned by two justices of the place where the applicant resides, certifying that to their knowledge or belief such person is about to carry on the practice of anatomy. Notice is to be given of the place where it is intended to examine bodies anatomically one week at least before the first receipt or possession of a body. The secretary of state appoints inspectors of places where anatomical examinations are carried on, and they make a quarterly return of every deceased person's body removed to each place in their district where anatomy is practised, distinguishing the sex, and the name and age. Executors and others (not being undertakers, &c.) may permit the body of a deceased person, lawfully in their possession, to undergo anatomical examination, unless, to the knowledge of such executors or others, such person shall have expressed his desire, either in writing or verbally, during the illness whereof he died, that his body might not undergo such examination; and unless the surviving husband or wife, or any known relative of the deceased person, shall require the body to be interred without. Although a person may have directed his body after death to be examined anatomically, yet if any surviving relative objects, the body is to be interred without undergoing such examination. When a body may be lawfully removed for anatomical examination, such removal is not to take place until forty-eight hours after death, nor until twenty-four hours' notice after death to the anatomical inspector of the district of the intended removal, such notice to be accompanied by a certificate of the cause of death, signed by the physician, surgeon, or apothecary who attended during the illness whereof the deceased person died; or if not so attended, the body is to be viewed by some physician, surgeon, or apothecary after death, and who shall not be concerned in examining the body after removal. Their certificate is to be delivered with the body to the party receiving the same for examination, who within twenty-four hours must transmit the certificate to the inspector of anatomy for the district, accompanied by a return stating at what day and hour, and from whom, the body was received, the date and place of death, the sex, and (as far as known) the name, age, and last abode of such person; and these particulars, with a copy of the certificate, are also to be entered in a book, which is to be produced whenever the inspector requires. The body on being removed is to be placed in a decent coffin or shell, and be removed therein; and the party receiving it is to provide for its interment after examination in consecrated ground, or in some public burial-ground of that religious persuasion to which the person whose body was removed belonged; and a certificate of the interment is to be transmitted to the inspector of anatomy for the district within six weeks after the body was received for examination. Offences against this Act may be punished with imprisonment for not less than three months, or a fine of not more than 50*l.*

The supply, under this Act, of the bodies of persons who die friendless in poorhouses and hospitals, and elsewhere, is said to be sufficient for the present wants of the teachers of anatomy; and the enormities which were formerly practised by 'resurrection-men' and 'burkers' have ceased.

ANCHOR. The anchor, which, under some form or other, must have been as ancient as ships of any magnitude, is mentioned by many Greek and Latin authors; by whom also its invention was ascribed to various persons. The first anchors were, most probably, what they now are among uncivilised nations, namely, large stones, or crooked pieces of wood loaded with heavy weights. The latter form is mostly used by the Chinese, and indeed upon our own coasts at the present day single heavy stones are used as anchors or "kitticks,' by fishermen. The first anchors had but one fluke; another was afterwards added: but the anchor was yet without a stock, as appears from ancient monuments, and must have been very incomplete. This addition may, therefore, be considered as the last step towards the present form. Each ship then had several anchors; the chief one was called *ἱερα*, or sacred, and reserved for the last extremity,—precisely as the largest and best is now used in emergencies under the name of "sheet anchor;" but the veneration paid to it has much declined since the custom of paying 5*l.* to the master on letting it go was discontinued in the navy. For the purposes of the present article, we shall notice first the mechanical action of an anchor; then the mode of its manufacture; and lastly, the changes recently introduced in its form.

The technical parts of an anchor, which must be borne in memory, are the following:—The *shank* is the main or central shaft; the *small* is the end of the shank near the top; the *throat* near the bottom; the *trend* two-thirds down the length of the shank; the *ring* is at the extreme upper end; the *stock* branches out immediately beneath the ring; the *arms* branch out at the other end of the shank; the *palms*, or *flukes*, are flattish portions at the ends of the arms; the *bill*, or *peak*, is the extreme end of each palm; and the *crown* is the part farthest from the ring.

It may suffice at present to state that the difference between *bower*, *sheet*, *stream*, *kedge*, and *spare* anchors, is rather one of size than of construction. Referring, therefore, to the annexed cut for an illustration of the several parts of an anchor, we proceed to show its mode of action.

A, the ring.

B E D, the shank.

B, the small.

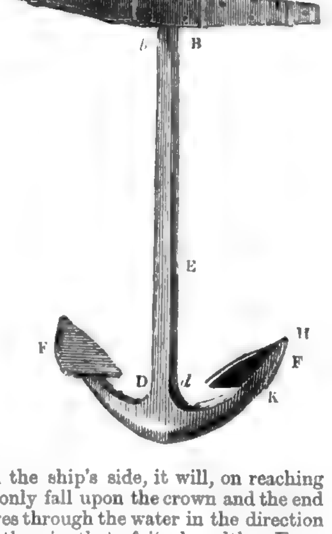
D, the throat.

E, the trend.

F D, H *d*, the arms.

F, the palm, or fluke.

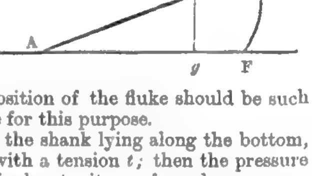
H, the bill or peak, or "pea."



When the anchor is let go from the ship's side, it will, on reaching the bottom of the sea, most commonly fall upon the crown and the end of the stock; because the stock moves through the water in the direction of its length with less resistance than in that of its breadth. From this position the anchor must be turned or canted over. The longer the stock, within the practical limits of stowage, the more certainly will the anchor turn properly; and, when hooked in the ground, the more powerfully will it resist any effort to overset it. Also, it is evident that the anchor will turn the more easily as the arm is shorter. In repairing old anchors, it is common to shorten the shank; in doing this, it is the custom also to shorten the stock in the same proportion. This, which is equivalent, in fact, to lengthening the arms, might, if carried to any extent, prevent the possibility of the anchor turning over, and therefore it appears that when the shank is shortened, the stock should remain unaltered. The amount of force required thus to overturn any given anchor might be found by calculation, or by actual trial; and it is remarked that the result of the former may be diminished by one-seventh when the anchor is under water.

The anchor being in the position of *fig.* 2, its weight, supposed to be collected at the centre of gravity, G (not including the stock), tends to force the fluke F into the ground; and as this pressure on F will evidently be greater, as the vertical line G g passes nearer to F c, this pressure is W. $\frac{A\,g}{A\,F}$ (W. = the weight, exclusive of the stock). As soon as the cable pulls from A, it causes the fluke to catch or hook deeper, that is, it forces the fluke down; and the position of the fluke should be such as to form the angle most favourable for this purpose.

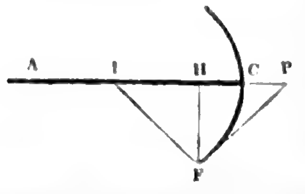
Fig. 2.



Suppose the arm C F imbedded, or the shank lying along the bottom, and the cable acting in the line C A with a tension t; then the pressure on the fluke taking place perpendicular to its surface, draw F I perpendicular to the fluke, and draw F P, tangent to the fluke, meeting

A C produced in P; then if P represent the tension t of the cable, I F will be the perpendicular re-action of the fluke, and P F the force which tends to drive it into the ground; draw F H perpendicular to C A, then H F is that part of P F which is perpendicular to the horizon, or is the effort of t to sink the fluke: let I P F $= a$, then F P $= t \cos a$, and F H $=$ F P $\sin a = t \cos a \sin a$, which is a maximum when $a = 45°$; or the fluke should be placed at 45° to the shank. Now, it is remarked by seamen, that when an anchor is once started, it is difficult and often impossible to get it to hold again, and as this case is the most urgent of all, it is apparently the one to which the position of the fluke should be calculated.

Fig. 3.



It would appear, since the weight of a large anchor bears a much higher ratio to any given tension of cable than the weight of a smaller one, that the solution of the problem ought to involve the weight of the anchor, which would give a different angle for anchors of different weights; but it appears from numerous experiments which Lieut. Rodgers has made on the qualities, as well as on the strength, of anchors, that an anchor, when dragged, always tends to rise out of the ground, thus following the direction in which the loosened soil affords a free passage;—since, therefore, it will not sink till it rests, and since its weight becomes less effective in pressing it farther the deeper it sinks, while the tension of the cable remains the same, it is thus constantly tending to the most favourable angle (when $= 45°$) till the arm is entirely buried.

It appears from *fig.* 2, that in shortening the shank, the fluke, making already in most anchors the angle with the shank, or F P I in *fig.* 3, too great, will become still more nearly perpendicular to the horizon. In many such cases the pull of the cable will produce scarcely any tendency whatever to sink the fluke; besides which it is to be observed that by lessening the horizontal distance A F, while F g remains the same, the pressure on the fluke is diminished, and thus on both accounts the qualities of the anchor impaired.

We now come to considerations relative to the strength of the anchor. It is obvious we have not the means of determining the amount of any of the forces concerned, but long experience has marked pretty nearly the limits beyond which the dimensions of anchors need not be carried. With these we can determine satisfactorily the preference which should be given to one form over another. The first strain that comes on the anchor when the cable is strained falls on the ring, which had been often broken or distorted, till its dimensions were of late years increased. This pull is conveyed along the shank to the lower arm, which it tends to break off at the greatest distance from the fluke, and therefore the thickness of the arm should increase towards the throat. The crown, which formerly was a circular arc, of late years formed an angle, till changed by Mr. Pering. The force to break the arm C F (*fig.* 3), is the re-action perpendicular to the fluke, or F I, against the tension of the cable. And the moment of this force to break the arm C F at C, is as the perpendicular from C on F I. If the arm F C be straightened into F P meeting A C in P, then the moment of the same force is as P F, which is considerably greater than before. It would be curious, therefore, to know what reason led to change from the curved to the angular form. In lifting or weighing the anchor, the cable acting perpendicularly to the end of the shank tends to break it, and hence the thickness of the shank should increase with its distance from the ring; also the breadth of the arms and the shank should be downwards. In order to obtain increase of length without either increase of weight or loss of strength, Lieut. Rodgers constructed his patent hollow-shanked anchor. The principle on which a hollow rod or bar is stronger than a solid one of equal sectional area is well known. Since the fluke from its breadth opposes greater resistance to being disturbed in weighing than the arm does, the axis of rotation will be towards the fluke, and accordingly the ground displaced by the angular motion of weighing being less than that displaced by fair pull,—and moreover the fulcrum or axis being near the throat in direct pull,—it seems that the force to lift an anchor out of the ground will be considerably less than the force sufficient by fair pull to bring the anchor home.

Before noticing the recent improvements in anchors, we will briefly detail the chief processes in making those of ordinary construction. Whether we view the forging of an anchor under the old state of things, or now that Nasmyth's steam-hammer works such wonders, it is a striking exhibition of industrial skill and labour. The shaft of a first-class anchor, nearly twenty feet long by ten or twelve inches thick, is too ponderous to be worked out of one piece of metal; and it has consequently to be built up of many pieces. Forty or fifty bars are sometimes laid together in a group, to be welded into one mass by powerful blows while at a white heat; but in modern times a smaller number of wider bars are more frequently used. The bundle of bars is brought to a highly-heated state, in a kind of oven formed wholly of coals, which completely surround the iron; but as the length of the shank is so great, only so much of it is heated at once as can be forged before it cools down too low. The fire is urged by ten or a dozen men; and when the mass is brought to a white heat, it is drawn out of the fiery furnace, swung round by means of the crane by which it has been suspended, and brought to bear on a large anvil. The men arrange themselves in a circle around the heated mass; and, guided by a foreman, they wield their ponderous hammers of sixteen or twenty pounds weight, and produce a rough music by their equal-timed blows.

But this was in the old times. If we now visit the government anchor smitheries, such as that in Devonport Dockyard, we find that steam has driven away something of the old picturesqueness—replacing it by a grandeur of its own. The anchor-shaft is no longer buried in a mere heap of blazing fuel, but is heated in a properly constructed furnace; the bellows are no longer worked by hand, but by the powerful blast of a steam-engine; the forgers need no longer to confine their operations to one small length, at a time, for a much greater length can now be managed before it cools down too low; and the circle of anchor-smiths less frequently wield their hammers, and expend their strength in blows which were once called powerful, but which have been superseded by something much more effective. Mr. Nasmyth's steam-hammer is a contrivance in which a powerful hammer or weight is allowed to fall by its own gravity, but is drawn up by the operation of steam-power; and this alternation of rising and falling occurs several times in a minute—much faster indeed than a man could wield a sledge-hammer. The white-hot anchor-shaft is placed upon an anvil immediately beneath the steam-hammer; and the blows which follow are so powerful and so quickly repeated, that the heated mass becomes forged in a wonderfully short space of time. Let the anchor-smiths group themselves as thickly as they may, and wield hammers the heaviest that human muscles can command—they cannot approach the amount of work which the steam-hammer effects. Even the *Hercules* which formed an intermediate stage between the sledge-hammer and the steam-hammer, and which consists of a heavy mass of iron worked by ropes, must yield in efficiency to Mr. Nasmyth's remarkable machine.

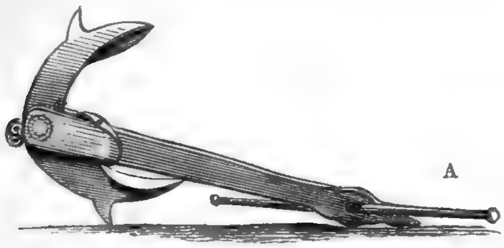
It would be impossible to notice all the improvements introduced or suggested in the form of anchors; but the chief novelties may consistently pass under review.

Mr. Pering introduced the plan of forming the shank of flat bars, of breadth equal to the depth of the shank. His greatest improvement was, however, that of forming the arms and part of the shank together—effected by splitting or dividing the bars, and throwing the ends back in opposite directions to form the arms; over the opening or angle thus formed is fixed a truss, and then to this are joined the flukes, and at the other end the remaining part of the shank.

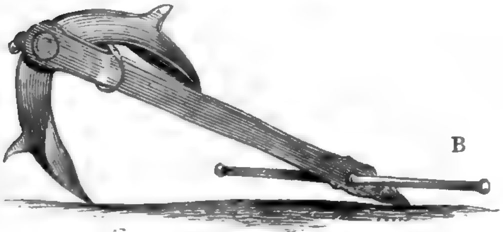
Lieutenant Rodgers introduced the hollow-shanked anchor; thus disposing the metal in the form which engineers know to be most profitable in proportion to its weight. The shank is, correctly speaking, not hollow in effect; for the square interior is filled up with a block of hard wood, to keep the iron bars or plates in their places; the principle, nevertheless, is that of a hollow shank, so far as strength is concerned. The shank is bound round with hoops at intervals.

In 1836 Mr. Meggitt patented an anchor in which the wide flukes or palms are dispensed with, the flukes being very little broader than the arms; while at the same time there is an increased width given to the crown by the addition of a triangular piece of iron. About the same period another form of anchor was introduced, in which the several parts were formed of distinct pieces of iron, so that it might be stowed away with great facility, or conveyed piecemeal by a boat which could not carry the whole anchor. The arms were formed of one piece, the shanks passing through the crown; the stock was also separate and secured to the shank when required; and the whole were so adjusted as to be put together in a short space of time.

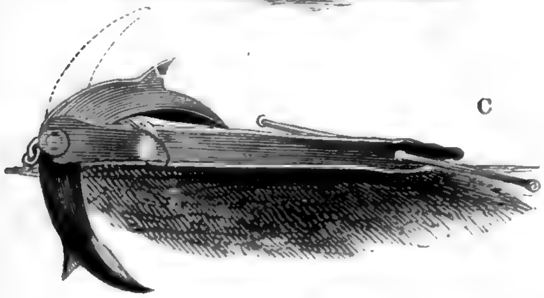
Mr. Porter's invention relating to anchors has, through various circumstances, led to very important results, and to a curious legal decision. The objects designed to be attained by this new construction are mainly the two following:—the avoidance of "fouling," by the cable passing over the exposed fluke of the anchor when the vessel is swinging in a tide-way; and the avoidance of injury to the vessel itself, in the event of falling upon her anchor. The peculiarity of the plan consists in giving to the arms and flukes a freedom of motion round a pivot or fulcrum at the end of the shank: thus departing at once from the rigidity usually observed in the construction of anchors. The arms and flukes are forged wholly independent of the shank, and have a hole drilled transversely through the centre, for the reception of the iron bolt which connects them with the shank. To give a familiar illustration, the joint may be described as of that kind which connects the wires of an umbrella with the ribs, so as to give a freedom of motion round the pin or bolt as an axis. When an anchor thus constructed is dropped from the vessel, it descends swiftly and strikes against the bottom of the sea with great momentum (estimated, with an anchor of ten hundredweight and a depth of twenty-four fathoms, at 45 tons). When the anchor rests fairly on the ground, its first position (A) is with the lower peak, or tip, in contact with the lower surface of the shank, the upper peak being as far as possible from the shank. Then the slightest movement of the cable suffices to disturb this position, and to bring the lower peak into a direction fitted to penetrate the ground (B). This libration continues until the upper peak touches the upper surface of the shank, and the lower peak is directed almost perpendicularly: a position very favourable for penetration, which then takes place. The shank and stock then lie flat on the ground (c); and the anchor, if pulled in the direction of the shank, has a tendency to fix itself more firmly in the ground, by keeping the



A



B



C

lower fluke almost perpendicular in the ground. Captain Denham, of the Marine Surveyor's Department at Fleetwood, gave a report of some experiments which he had tried in 1840 on the new swivel anchor, and states the following as the results to which he had arrived:—"It is almost impossible to foul it; it bites quickly into the most stubborn ground; it holds on to the shortest stay-peak; it cannot lodge on its stock end; it presents no upper fluke to injure the vessel herself, or others, in shoal water; it cannot injure vessels' bows when hanging acock-bill, as merchant-vessels find a convenient practice; it is not so likely to break off an arm, or part in the shank, as anchors with fixed flukes do, because the construction of these arms can be of continuous rod-iron, and the fulcrum of leverage is so much nearer the ring, owing to the pea of the upper fluke closing upon the shank; it is a most convenient anchor for stowing inboard on a voyage, as the flukes can be easily separated and passed into the hold; it can as easily be transported by two boats when one would be distressed by the whole weight; it produces the desired effect of ground-tackle at one-twentieth less weight." ('Unit. Serv. Journ.,' March 1840.)

Mr. Porter's anchor has been the basis on which improved forms have been introduced by Trotman, Honiball, and other inventors. Trotman's construction, patented in 1852, differs from Porter's chiefly in these points—that the palms are fixed intermediately on the breadth of the arm, instead of in front; and that the horn is of greater width than the arm, for a different shape is also given by Trotman to the upper part of the palm, in order that, as the tension of the cable buries the palm deeper into the ground, the upper flap of the palm being turned over so as to form the spur or horn, admits of the clay or sand, or mud being easily 'delivered' like the soil from a ploughshare. Hence it is often seen at anchorages which dry at low water, that Trotman's anchor buries itself totally some feet below the surface (a valuable consideration when a ship is riding heavily on a *lee-shore!*) while its shape insures ready extrication when the cable is hove full '*stay a peak:*' for its *ploughing qualification is available in any direction.* As regards *originality*, a notable legal decision was arrived at in 1855. Mr. Porter took out his patent in 1838; and an extension of the patent right was obtained in 1852; but this extension underwent a sudden check. During an action for infringement of patent, in 1855, it was proved that Porter's anchor was not a new one within the terms of the letters patent. Many years antecedent to 1838, Mr. James Logan had invented and made public the contrivance of a swivel anchor; he exhibited drawings and models; nay, he made such an anchor in 1826 for a steamer named the 'William Huskisson.' These facts were not known to Mr. Porter in 1838; but they vitiated his patent. Accordingly, in 1855, Mr. Pemberton Leigh, on the part of the Judicial Committee of the Privy Council, pronounced Porter's patent to be null and void, and the invention therefore open to the free use of any one.

In July, 1852, a trial of anchors was made at Sheerness, by order of the Admiralty. Those selected were to be bower anchors of 25 cwt.; and they were to be tested with regard to the following qualities;—"strength; holding, particularly when at a short stay, and being obliged to make sail; weight, and facility for stowing; quick holding; sweeping; tripping; fouling," &c. There were four modes of testing devised, in relation to the kind of ground chosen. The anchorsmiths of all nations were invited to compete, and several competitors appeared. The experiments occupied many days, and two or three of the anchors performed admirably. The most efficient appeared to be Porter's under the improved form introduced by Trotman.

Many patents for anchors have been obtained within the last few years—such as Firmin's in 1854; Scott's in 1855, and Hunter's in 1856; but they related chiefly to slight modifications of constructions already in use.

The number of anchors carried at both the bows and stern of a ship have been finally reduced to four principal, and these all at the bows. The anchors supplied to men-of-war are the best and small 'bowers,' the 'sheet,' and the 'spare:' these are of the largest size; to which are added, the 'stream' and the 'kedge,' which are used for particular or for temporary purposes, and are usually carried 'in board.' Since there is but small difference in the form of anchors of different weights, the stream of a large vessel serves for the bower of a smaller. Various rules have been given for the dimensions of anchors. The rough rule in the navy is, 1 cwt. to a gun; thus, an 80-gun ship will have an anchor of 80 cwt.; and a merchantman of 200 tons having an anchor 10 cwt., 5 cwt. is added afterwards for every 100 tons: thus 300 tons would give 15 cwt., and so on. The principal dimensions of the anchors in the navy may be stated shortly thus: calling the shank 10, the arm is about 3, the breadth and depth of the palm about half this, the thickness or depth at the small, ·42, at the throat ·6, which are nearly the dimensions of the arms also, and the breadths about $\frac{2}{3}$ of these, the edges being rounded. The weight of an anchor of 10 feet in length is, according to Pering, about 11·4 cwt., and since, if the forms of all anchors were alike, the weights would be as the cubes of the lengths, the weight of any anchor might be found (nearly) by multiplying the cube of its length by ·0114. The recent improvements in anchors are however likely to derange the old rules in respect both to the dimensions and weights of the several parts.

The largest anchors ever yet employed were those adopted by Mr. Brunel in the launching of the 'Great Eastern,' or 'Leviathan,' in the winter of 1857-8. They were required, for the enormous strain incident to that operation, to bear a breaking test of 110 cwt. each; and the chain cables for them, by Messrs. Brown and Lenox, were the largest ever made.

In the technical employment of anchors on board ship, an anchor is said to be 'foul' when the cable is any way entangled with it; to 'come home,' when the ship drags it; to be 'a-wash,' when the stock is hove up to the surface of the water; to be 'acock-bill' when hanging vertically; and to be 'stay a peak' when just ready to lift from the ground.

A'NCHORET, sometimes written, and more correctly, Anachoret, a Greek word (ἀναχωρητὴς), signifying a person who has retired from the world. Under Christianity they sprung up about the middle of the 3rd century in Egypt and Syria, where many believers went to hide themselves in caves and solitary wilds, from the fury of the persecution which arose under the Emperor Decius. Paul, commonly called the hermit, has the credit of having been the first regular anchoret. A distinction, however, came afterwards to be drawn between anchorets and hermits: the former name being given only to those who rigidly confined themselves to their caves or cells; and the latter to those who, although they had broken off all commerce with the world, still wandered about at large in the wilds to which they had retired. Both descriptions of recluse were entirely distinguished from the Cœnobites, or those living in communities. Many of the anchorets were laymen; and there were also female as well as male anchorets. From nearly the commencement of the 7th century, the Church assumed a jurisdiction over anchorets; and persons were not allowed to enter upon the mode of life in question, except by permission of their ecclesiastical superiors, and after an appointed ceremony had been performed, at which the bishop presided. Churches and religious houses in the middle ages would sometimes keep an anchoret shut up in a cell, which was usually attached to the choir of the church. Such an attraction brought great crowds of the devout and the curious to the holy place, which benefited much by their offerings. It was eventually found necessary, in our own as well as in other countries, to lay down certain regulations with a view of discouraging the adoption of this solitary life. The most singular species of anchorets recorded in the history of the Church, is that which arose in Syria in the 5th century, and of which Simeon Stylites was the founder. This zealot and his followers, instead of resorting, according to the customary fashion, to caves, elevated themselves into the air, on lofty pillars of stone, on the tops of which they passed their lives. They have hence received the names of pillar saints, holy birds, and aërial martyrs.

ANCHUSIC ACID ($C_{35}H_{20}O_8$?).—(*Anchusin.*)—A resinoid colouring matter obtained from Alkanet root (*Anchusa Tinctoria*). It is insoluble in water, but soluble in alcohol, ether, and oils, to which it imparts a fine carmine red colour. It is hence used for colouring hair-oil. Its alcoholic solution is bleached by exposure to light.

ANCHUSIN. [Anchusic Acid].

ANCHYLO'SIS, a Greek word (ἀγκύλωσις), signifying *a bending*. If the Greek orthography were strictly followed, the word would be written *ankylosis*.

An essential part of the apparatus of locomotion in animals consists of the structure termed a joint. [Joint.] Joints are so constructed as to produce various kinds and degrees of motion, in the execution of which it is necessary that the different parts constituting the joint should be in close contact with each other. Organised living surfaces, in close contact with each other, have a tendency to grow together; but such a union would at once destroy the action of a joint, and a specific apparatus is provided for the express purpose of preventing this event. What are termed articular surfaces, that is, the surfaces of joints, are covered with a thin and delicate membrane which secretes a peculiar fluid of an unctuous or oily nature, termed *synovia*. This synovia, the oil of joints, is in general effectual in keeping separate and distinct the different parts of the joint, however closely and for however long a time they may be in contact with each other; nevertheless, it does occasionally happen that a firm and complete union takes place between the different articular surfaces: when this occurs, it constitutes what is technically termed anchylosis, or, in common language, a stiff joint. An anchylosis, or a stiff joint, consists then of the immoveable union of two bones naturally connected together in such a manner as to form a moveable joint. All the moveable bones forming joints may become consolidated together, or anchylosed; and cases are on record of a general anchylosis of all the bones of the human body. Whatever keeps a joint motionless for a long time together may give rise to anchylosis. Hence it is apt to occur after the fracture of a bone in the neighbourhood of a joint; because it is necessary to the cure of the fracture that the limb should be fixed in one position, while the inflammation occasioned by the violence that produces the fracture often spreads to the joint, and it is one of the ordinary effects of inflammation to agglutinate and consolidate the parts inflamed. Hence inflammation, sprains, dislocation, shocks occasioned by leaping or falling on the feet from great heights, ulcers, are the common causes of anchylosis. But anchylosis cannot always be considered in the light of a disease; at any rate, it is sometimes the happy termination of a formidable malady. The natural cure of many painful and dangerous diseases of the joints is the formation of an anchylosis. When an anchylosis is forming, and is clearly inevitable, and is indeed a thing to be desired, the position in which the limb is kept, or the position in which the bones are allowed to unite, is a matter of great importance to the future comfort of the individual. When, for example, from injury done to the hand, the joints of the fingers are undergoing the process of anchylosis, it is very important to keep the fingers bent, because, if they anchylose in that position, the hand will be more useful than it could be were the fingers permanently extended. On the contrary, when there is danger of anchylosis of the knee-joint, the limb should be kept as straight as possible, because, if the leg be extended, the limb will be more useful than if it were permanently bent. On the other hand, when anchylosis of the elbow-joint cannot be prevented, the limb should be kept bent.

The term anchylosis is also employed to denote a natural union of bones. Thus, bones, or parts of bones, which are separate in the early stages of their growth, and afterwards become united, are said to be anchylosed. Also in the case of animals belonging to different divisions of the animal kingdom, bones which remain separate in one class through life, are found united in another class, and anchylosis is said to have taken place.

ANCIENT, ANCIENTS. The term *ancient*, which we derive from the French word *ancien*, has the primary meaning of "very old," as when we say "an ancient building," "an ancient family," implying only that many generations have passed since they first came into existence. But it is also used in a more limited sense, with reference to a certain period in the existence of the human race: as when we speak of ancient, as distinguished from modern, history; of the ancient classics, ancient literature, and generally, of the *ancients*. The boundary line between ancient and modern in this latter sense is not very accurately drawn; but according to the common acceptation of the terms, the period of the ancients seems to be closed by the final and complete overthrow of the Western Roman empire. With reference to the nations over which that empire extended, the distinction is not altogether arbitrary, or without an intelligible reason. The overthrow of the Roman empire marks the commencement of a new order of things, when we begin to discover the rudiments of those powerful independent nations, of those various languages and peculiar institutions, which so remarkably distinguish a large portion of what is called modern Europe, from Europe under Roman dominion. There is of course a short interval, which may be considered as doubtful ground, for the possession of which the terms ancient and modern will always be allowed to contend.

It is plain that the reason here given for the commonly received distinction is applicable only to the West and South of Europe; yet the same distinguishing terms are familiarly used, and in many cases the same date arbitrarily assumed with reference to the rest of the world. This practice is attended with many difficulties, and produces no little confusion. The Eastern Roman empire, for instance, survived the Western by many centuries; nor can any good reason be given why the subjects of Justinian and his predecessors should be classed among the ancients, and those of his successors among the moderns. If the question were asked, where should a Greek author in a late period of the Eastern empire be placed, we could not call him either an ancient or modern Greek writer without giving cause for considerable misapprehension. The use of the term mediæval may, however, to a certain extent remove the difficulty—at least in many cases. In the case of the Oriental nations, the terms ancient and modern are still applied, and often perhaps with no very distinct notion of their import, even by those who employ them. We hear commonly of ancient and modern Persia, ancient and modern India. Now, in the case of the Persian empire, in seeking for a date, we might choose between the conquests of Alexander the Great, the irruption of the Parthians, the restoration, as it is called, of the old Persian dynasty, and its subjugation by the Mohammedans. Any one of these events, and especially the last, would furnish perhaps better ground for the distinction of ancient and modern Persia, than anything which occurred at the time of the overthrow of the Roman empire.

It might be expected that the convenience of having at hand such terms as ancient and modern would often lead to some abuse, and this is particularly observable in the vague reference so frequently made to "the ancients." There is no definition which excludes from their number any who lived from the time of Noah down to the last Roman emperor; and it is obvious, that there is not much which can be safely predicated of a class so large and comprehensive; yet we often hear of what "the ancients" said, and did, and thought. Allusion is made to the military tactics or the philosophy of the ancients: comparisons are instituted between the literature of the ancients and moderns; and we are told of the sentiments on certain subjects entertained by the heathen ancients. The truth is that, by "the ancients," we must understand, on many of these occasions, Greeks or Romans at certain periods of their national history; and even thus limited, there are few assertions which will hold good of "the ancients" generally. For the most part, perhaps, the looseness of the expression is corrected and limited by the subject or the context; but it is also true, that real misapprehension has arisen from the practice of throwing together and confounding the most dissimilar things by the help of this comprehensive term.

This is not the place to enter on the consideration of ancient and modern history; but there is an evil in some measure connected with the use of these terms, which it may be worth while to notice. It is to be feared that the common division of the subject of history into two parts, ancient and modern, too often conveys the notion of an actual separation which does not exist. The young student pictures to himself a great gulf between them. When busy with the ancient part of the subject, he imagines himself to be conversing with beings of a different nature from himself. He believes the narrative, but is affected by it much as he would be by a work of fiction. When he has crossed the gulf, and passed from the obscure regions of ancient history into the stronger realities of modern times, he converses freely with beings of the same flesh and blood with himself. It is not requisite to enumerate all the bad effects which must arise from this impression. It is evil enough that the student must necessarily overlook the important fact, that the subjects of what are called ancient and modern history are so far one and indivisible, that a comprehensive view of the ancient part is necessary for the profitable study of the modern.

ANCIENT DEMESNE. [Manor; Socage.]

ANCIENT LIGHTS. [Lights.]

ANDAN'TE, in music, is the third in order of the five classes into which musical movement is divided [Allegro], and the medium between the extremes of slow and quick.

The music of Corelli, Handel, and their contemporaries, was generally much slower than that which prevails at present, and Andante was then used to denote a moderate degree of quickness: now it indicates a steady, calm movement, rather inclining to slowness than the reverse. It also enjoins a more than ordinary attention to the measure, to the equality of time given to each bar. This term is also used substantively: thus we say, 'an Andante of Haydn,' &c

ANDANTI'NO, in music, is the diminutive of 'andante.' It affords a curious example of the vagueness of musical terms, that musicians are not agreed whether this diminutive ought to mean 'less slow,' or 'less quick.' When the word andante is used, as by the old masters, to denote a degree of quickness, its diminutive abates its motion: when employed to indicate a movement rather slow than quick, as in the present day, the diminutive increases its motion. For want of adverting to this fact, much misapprehension and some disputes have arisen. It, however, seems to be agreed, that andantino now shall signify a movement quicker than andante—that it shall be the medium between the latter and allegretto.

ANDRO'MEDA, a constellation, so called by the Greeks from Andromeda, the mythological daughter of Cepheus and Cassiopeia, who was bound to a rock and thus exposed to a sea-monster, from whom she was delivered by Perseus. This constellation occupies a considerable region of the heavens below Cassiopeia, by which it may be thus found. A line drawn through the brightest star of the five in Cassiopeia, marked β, and the pole star, passes through a star of the first magnitude in the head of Andromeda, marked α, and called Alpherat. A line drawn through ϵ Cassiopeiæ, at the other corner, and the pole star, passes through Almach in the foot of Andromeda, marked γ, while in the line between the two stars thus found, lies Mirach, marked β, in the girdle of Andromeda.

The following is an enumeration of the principal stars in this constellation, classified according to their magnitudes :

Magnitude.	Number of Stars.	Magnitude.	Number of Stars.
1st	1	4th	6
2nd	1	5th	8
3rd	2	6th	45

Hence the total number of the stars in this constellation which are visible to the naked eye amounts to 63.

The following are the designations of the various stars in Andromeda, down to the 4th magnitude inclusive :

Character.	No. in Catalogue of Flamsteed.	No. in Catalogue of British Association.	Magnitude.
α	21	4	1
π	29	155	4
ϵ	30	164	4
δ	31	166	3
ζ	34	215	4
ν	35	227	4
μ	37	252	4
β	43	334	2
	51	487	4
γ	57	628	3

ANEMO'METER (from ἄνεμος, the wind, and μετρέω, to measure), is an instrument for measuring the force of the wind, by finding what mechanical effect the wind to be measured will produce upon the apparatus. The first anemometer seems to have been invented by Dr. Croune, in 1667, but this did not answer its purpose well, and a better instrument was devised in the last century by Wolfius, which is described by him in his 'Elementa Matheseos,' vol. ii. p. 319 (Geneva edition, 1746). It consists of four sails, similar to those of a windmill, but smaller, turning on an axis. On the axis is a perpetual screw, which turns a vertical cog-wheel round a second axis, placed transversely to the former. To the second axis is attached a bar, on which a weight is fixed, so that the sails cannot turn without moving round the bar in a vertical circle. When the wind acts upon the sails the bar rises, and this continues until the increased leverage of the weight furnishes a counterpoise to the moving force of the wind. The number of degrees the bar moves through to produce this effect is measured on a dial, the hand of which turns on the axis of the cog-wheel.

Another form of anemometer was invented by Leslie, depending for its action upon the principle, that the cooling power of a current of air varies as its velocity. Another instrument depended on the evaporation of water, which, for any time, is proportional to the velocity of the wind. In all these forms, however, the force is measured either by the compression of a spring, or by the raising of some weight to a height varying with the force to be measured. The former method, though more convenient, is, owing to the diminution in elasticity by frequent compression, liable to give varying results.

The principle of Dr. Lind's anemometer is as follows :—A, a curved tube of glass, as represented in *figure* 1, is partially filled with water. The bore of the tube is diminished at the bottom, as a check on the oscillations to which, the water is subject from sudden variations in the force of the wind. The wind acts upon the open end A, and depresses the water to B, until the column of water b C, the difference between the levels B and C, is a counterpoise to the force of the wind on B. This difference can be ascertained by the graduated scale. Hence, when the area of the bore at B is known, and the height of b C observed, the column of water is found the weight of which is equivalent to the force of the wind. The velocity may thence be found by observing (AERODYNAMICS) that the velocities are nearly as the square roots of the resistances, and that the moving force of a wind of 20 feet per second on a square foot is 12 ounces.

Fig. 1.

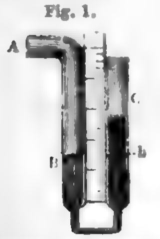


Fig. 2.

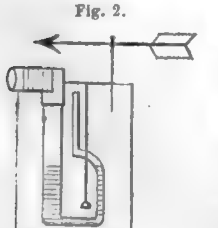


Lind's anemometer has been improved by Sir W. Snow Harris, who has reduced one of the limbs to the diameter of one-fourth of the tube which is open to the wind, and by making the first part of the scale horizontal the delicacy of the instrument has been much increased. He has also provided it with a plumb line, and with a light vane to facilitate the operation of observing. (See *fig.* 2.) Sir John Herschel, in the 'Manual of Scientific Inquiry,' recommends that in using this instrument in cold climates, a saturated brine which does not freeze should be substituted for the water; its specific gravity is 1·244, so that the force given by the table must be multiplied by this factor.

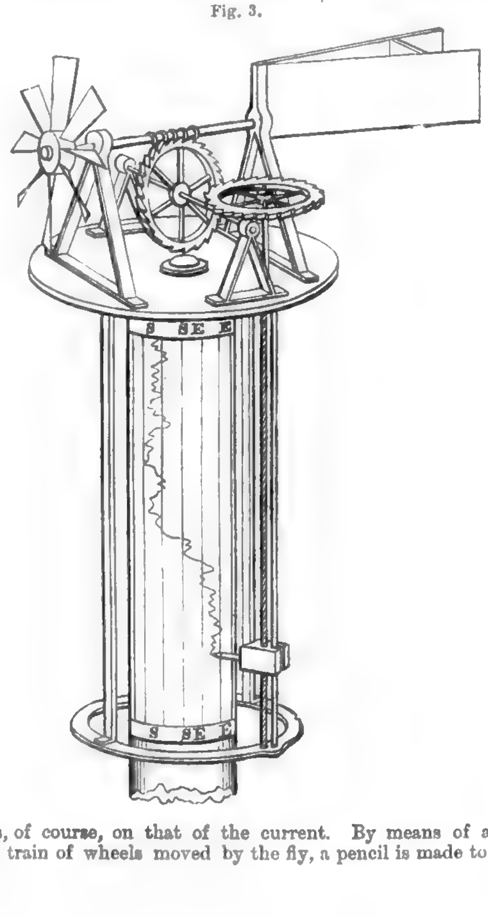
The following table, calculated by Dr. Hutton, and given in his 'Mathematical Dictionary,' is based upon some experiments made with Dr. Lind's anemometer, at Woolwich; it may be used with that instrument, and indicates what velocity of wind corresponds to various differences between the levels of the liquid, and the consequent force of the wind. Thus, when the column of liquid is 9 inches, the velocity is 108 miles per hour, and the pressure on the square foot is 43·9 lbs., producing a most violent hurricane; so that in the greatest storms the difference between the atmospheric pressures on the windward and leeward sides of any object does not amount to $\frac{1}{50}$th of the pressure on the leeward side, which, we know, is capable of supporting a column of water 32 feet, or of mercury 30 inches.

Difference of Levels in inches.	Force of Wind in pounds.	Velocity per hour in miles.
$\frac{1}{4}$	1·3	18.0
$\frac{1}{2}$	2·6	25.6
1	5·2	36·0
2	10·4	50·8
3	15·6	62·0
4	20·8	76·0
5	26·0	80·4
6	31·3	88·0
7	36·5	95·2
8	41·7	101·6
9	46·9	108·0
10	52·1	113·6
11	57·3	119·2
12	62·5	124·0

In Regnier's anemometer, a bar, carrying a flat wooden surface at right angles to it, protrudes from a box, through a hole in the front of which it slides. This bar is met by a spring, which resists its further entry, until force is applied against the wooden surface. In the interior of the box, the under side of the bar carries rackwork, which plays on a cog wheel, the axis of which, passing through a side of the box, carries a hand round a dial-plate. The flat surface of wood is presented to the wind, which presses upon it and forces back the bar, carrying the cog wheel and hand through an angle, greater or less, according to the greater or less impulse of the wind.

Various other contrivances have been proposed, the most important of which are by Dr. Whewell and Mr. Osler. In Whewell's anemometer (*fig.* 3) a windmill fly is, by the action of a vane, constantly presented to the wind, and the velocity of the revolutions of the fly

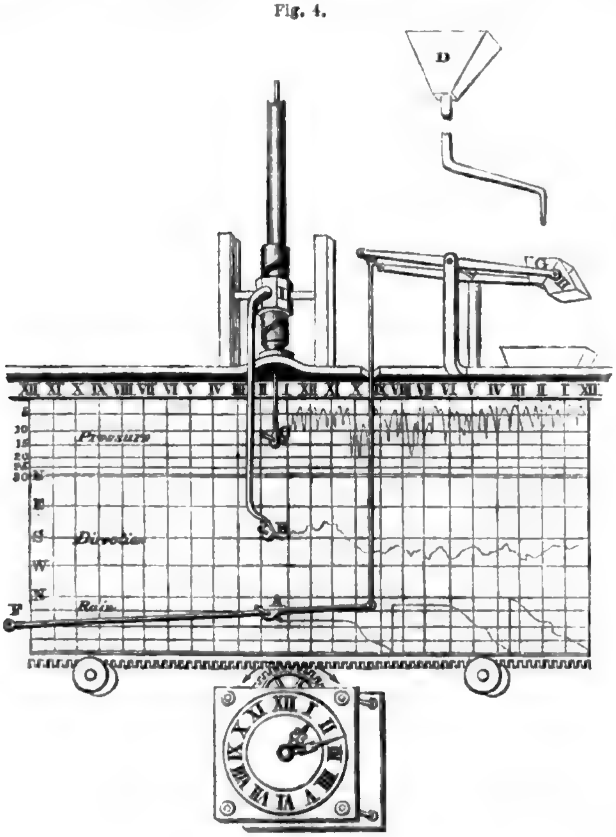
Fig. 3.



depends, of course, on that of the current. By means of an intermediate train of wheels moved by the fly, a pencil is made to descend over a fixed cylinder, producing thereon a trace of variable length, according as the wind varies in velocity. The surface of the fixed cylinder is divided into sixteen or thirty-two equal parts by means of vertical lines, the spaces between which correspond with the points of the compass, and between or upon these divisions the pencil is moved about by means of the vane, and the trace that it leaves shows the *direction* of the wind. The pencil, however, has two motions, one from above, downwards (10,000 revolutions of the fly causing the pencil to descend $\frac{1}{20}$ of an inch), and this motion increases as the wind blows more strongly, and by the extent of its depression registers the whole *amount* of wind that has been blowing. The other motion depends on changes of the quarter from which the wind blows; the pencil and its frame are carried round by the vane, so as to register the *direction* of the wind. Thus, if the fly revolve in the simple proportion of the velocity of the wind, the trace marked by the pencil describes a space proportional to that which a particle of air would describe in a given direction in a given time, taking into account the strength of the wind and the time for which it blows. The constant *wavering* of the wind causes the pencil to describe, not a single line, but an irregular broad path, something like the shadings in the coast of a map. The middle of this line will give the mean direction of the wind, while its length will be in proportion to the product of the velocity of the wind and the length of time during which it blows in each direction, which product is called its *integral force*.

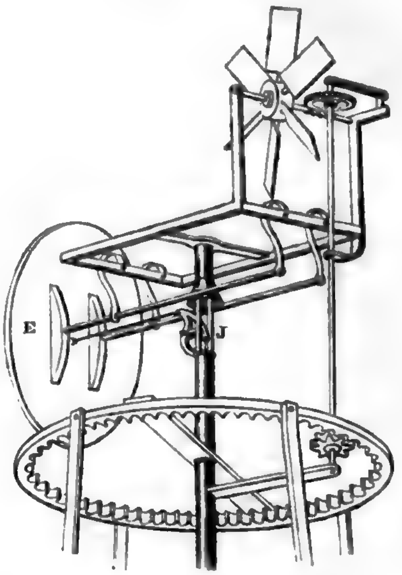
A great objection to the above form of anemometer is the amount of friction involved in the method of converting the rapid motion of the fly into a slow descending motion, and in the mode by which the pencil is made to move against the fixed cylinder. Osler's anemometer has some advantages over Whewell's. This instrument traces the direction of the wind and its pressure on a given area, together with the amount of rain, on a register sheet divided into twenty-four portions, corresponding with the twenty-four hours of the day. The action of this instrument will be understood by referring to *fig.* 4,

Fig. 4.



which represents the parts adjoining the register-paper. The central portion of this paper has a series of lines corresponding with the cardinal points of the compass, for indicating the *direction* of the wind. The upper part of the paper has a series of lines corresponding with the *pressure* in pounds on the square foot, while the lower part of the paper has a series of lines corresponding with given quantities of *rain*. There is also a series of twenty-four vertical lines, corresponding with the twenty-four hours of the day, so that a new register-paper, being properly placed on a board, is carried along upon friction-rollers, by means of a clock, behind the three pencils A, B, C, which may be regarded as the indexes of the machine. The pencil B, which marks the direction, is operated on by means of a set of vanes (*fig.* 5), turning vertically in a plane at right angles to that of the pressure-plate (E, *fig.* 5), and driving a cog-wheel, which rolling on a fixed cogged circle, turns the rest of the apparatus round, so as to present the edges of the

Fig. 5.



sails to the current when it is no longer turned by it either way: under these circumstances, the pressure-plate is placed at right angles to the vanes, and is acted on with full effect by the wind. As the vane or cap turns in the direction of the wind, a spiral worm on the shaft near its lower end raises or lowers the fixed nut I, from which springs the arm which carries the pencil B; this pencil traces a mark on one of the long lines of the register when the wind is blowing from one of the cardinal points, or between those lines, if it be blowing from intermediate points. The pressure-plate E is made to face the wind by means of the vane or cap. It is suspended by means of four springs, which yield to gentle winds, while a stronger spring receives the more violent pressure of a high wind. The motion of the plate is transmitted to the register-paper by means of a wire connected by the bell-crank J with another wire, which descends through the hollow upright shaft, and is kept stretched by a spiral spring. This wire carries the upper pencil C, which of course descends lower in proportion as the pressure-plate E is pushed back, and returns to the top of the paper when the pressure ceases. In this way, the distance to which the pencil is depressed shows, by means of a number of irregular parallel lines, the pressure of the wind in pounds on the area of one square foot, or its velocity in miles per hour. For registering the rain, the pencil A is attached to a lever A F, *fig.* 4, which is moved by the following contrivance: A rain-receiver, D, is placed on the roof of the house, and the water which pours into it is conducted into one of the two divisions of a gauge, G H, balanced on an axis and supported by a second balance: as the water accumulates in G (for example), the second balance begins to descend, and thus raises the upright rod to which the lever F A is attached, when the pencil, being raised with it, makes a mark on the paper, which represents the quantity of water collected in the gauge. When this quantity is equal to a certain depth of rain or to a certain number of cubic inches on a square foot, the gauge becomes upset by the weight of water, the water is thrown out, and the other compartment, H, is brought under the pipe; the effect of which motion is to send the pencil to the bottom of the paper, and it only begins to rise again when more rain is collected. Of course, the heavier the rain, the sharper will be the angles formed by the trace of the paper; whereas, if the rain be gentle, the elevating or diagonal lines will be drawn out to a considerable length; and lastly, if there be no rain, the pencil will trace a horizontal line, such as is represented in *fig.* 4, from VI. to VIII½, and from X½ to I.

Thus it will be seen, that as the register-paper is being constantly moved forwards by the action of a clock, the three pencils mark the direction and pressure of the wind, together with the amount of rain. The register-paper may be ruled for twenty-four hours, or for a week, and it may be placed vertically, as at the Royal Exchange, London, or laid horizontally on a table, as at the Meteorological Observatory at Greenwich, where the register, being on a larger scale, is changed every day. Mr. Osler has further improved his anemometer in the following manner: A sheet of plain paper, placed in the instrument under a registering pencil, is moved forward by rotating hemispherical fans, at the rate of one inch for every two miles of air that passes; this same pencil, having a lateral motion given to it by a vane, records the point of the compass from which the wind blows; and a clock-hammer descending every hour, strikes its mark on the margin of the paper to express the time. Thus in a single line are given, 1st, the length of the current; 2nd, the direction of the current; 3rd, the time occupied in passing a given station marked hourly, or at any shorter interval that may be desired.

The Rev. W. Foster, of Sturbington, near Portsmouth, has contrived an ingenious anemometer, which is fully described in Sir W. Snow Harris's 'Report on the Working of Whewell's and Osler's Anemometers at Plymouth during the years 1841,-42,-43,' presented to the British Association for the Advancement of Science in 1844, to which we are indebted for some of the preceding details. Foster's anemometer consists of a cross horizontal fly three feet in diameter, with four vanes each six inches square, and so contrived as to revolve in one direction only. The revolution of this fly imparts motion to a vertical shaft, at the lower end of which is an endless screw, which is connected with a train of wheels to a disc, twenty-two inches in diameter, which is caused to revolve slowly in a horizontal plane, and this disc thus registers the revolutions of the fly, which may be in any convenient proportion to those of the disc.

By means of a second vane and a vane-rod a second disc, nine inches in diameter, is made to revolve. There is also a rain-receiver on the roof, and a pipe by which the rain descends into a balanced gauge, the reciprocating motion of which causes an axis to work in a toothed wheel under the disc, through a space proportional to the quantity of rain delivered at each tip of the gauge. There is also a rod set on friction-rollers, and furnished with a rack adapted to the tooth of a horizontal rod projecting from the centre of a clock. There are twenty-four teeth in the rack, so that the rod is moved hourly one division, by which motion three pencils are hourly moved upon the respective discs, so that traces are obtained of the direction and velocity of the wind, and of the rain for every hour.

We give the following table as a specimen of the interesting results of the operation of this instrument. It shows the total and mean hourly velocity of each wind in miles.

Points of Compass.	Total Velocity in miles per hour.	Number of hours of each wind.	Mean hourly Velocity in miles.

Professor John Phillips had, in the Great Exhibition of 1851, an anemometer for collieries, hospitals, &c., for ascertaining the velocity of the current in the ventilation of such places. The pressure is received on a semicircular disc of cardboard, suspended by the diameter and measured on a graduated arc. By tables calculated from the equation, $\text{vel.} = M\sqrt{\frac{\sin.\,\theta}{\cos.^2\theta}}$, the velocity is obtained in terms of the angle. M. de Hannault also exhibited a small travelling anemometer, consisting of a series of fans which, by a simple contrivance, could be stopped or set in motion almost momentarily. Its chief object was to determine the horizontal velocity of the air in a given time.

In the anemometer erected at Kew Observatory Dr. Robinson's method is adopted, namely, that of measuring the velocity of the wind by the rotation of a system of hemispherical cups, the direction being indicated by a double-wheel fan, like the directing vane at the back of a windmill. A stout tubular support carries the whole of the external part of the instrument, including the measurer of velocity, the direction vane, and a rain gauge. All the rotatory parts of the anemometer run upon friction-balls. The shaft of the apparatus for measuring the movement of the wind by means of a diminishing train of wheels, is made to turn a cylinder upon which is wrapped a sheet of paper of the kind used for metallic memorandum-books, which paper receives a trace from a brass style. The sheet of paper is divided into two sections, upon one of which is recorded the motion of the wind, and upon the other the direction. As the cylinder is being turned by the action of the wind, a clock carries a pencil along the cylinder at the uniform rate of twelve inches in twenty-four hours. To the lower end of the direction-shaft is attached a spiral of such a figure that equal angles correspond to equal increments of radius; the edge of this spiral consists of a thin slip of brass, which touches the paper and records the direction of the wind on a rectilinear scale. When the sheet of paper is taken off the cylinder after the lapse of twenty-four hours, the motion of the wind and the direction are both found projected in rectangular co-ordinates. This self-registering apparatus was designed and constructed by Mr. R. Beckley, assistant in the observatory.

In a letter to the writer of this article Mr. Beckley remarks :—"The principal improvement I think, consists in the method of mounting, by the application of the hollow shaft to the direction vanes; as in all cases where the cups have been used the velocity and direction of the wind have been two distinct erections, whereas all that is necessary in my case is a base to bolt the column upon. I also economise space within the building. The method of registration consists in using metallic paper, upon which brass becomes a pencil; the form of which is a very thin-threaded screw, whose pitch, in the case of the velocity-pencil, is equal to a scale of fifty miles upon the paper. By this means I get a very open scale in a small space. The pitch of the direction-screw is equal to any openness of scale that is desirable. By using this form of pencil I overcome the difficulty attending the old method, namely, the pencil shifting off the scale, to obviate which, it was usual to have three sets of scales upon the paper; but even then, should the wind go twice round in the same direction, it ceased to indicate, whereas in my arrangement it must at all times register."

With respect to anemometric observations at sea, Mr. Welsh, Director of the Kew Observatory, gives the following method of making allowance for the effect of the ship's motion upon the observed velocity and direction of the wind :—"By means of a portable Robinson's anemometer, provided with a means of observing the total number of turns made by the rotating part in any given time, observe the *apparent* velocity of the wind, and record it in knots per hour. By an anemoscope of any kind register the *apparent* direction of the wind. From the log-book take the rate and direction of the ship's motion. On a slate or other similar surface scratch a permanent compass circle: set off from the centre of the circle, on the radius of the direction of the ship's head, by any convenient scale, the number of knots per hour the ship is going; from this point draw a pencil line parallel to the direction of the wind as observed by the anemoscope (that is, the *apparent* direction *to* which the wind is *going*); set off on this line the number of knots per hour as shown by the anemometer; draw a line from the centre of the circle to this last point. The length of this line by the scale adopted, gives the *true* velocity of the wind, and its direction (carried backwards) shows the point *from* which the wind is *coming*. A parallel ruler divided on the edge is all that is required besides the slate. It would be easy enough to contrive some mechanism to save the trouble of drawing lines, but it would not, I believe, be any real simplification, and would increase the expense. The train of indicating wheels might be so arranged that they at once indicate knots per hour, without reference to tables, and can be readily set to zero for a fresh observation." ('British Association Report,' 1856.) Professor C. Piazzi Smyth, from a series of observations communicated to him by Captain H. Toynbee, concluded that the only unexceptionable station for anemometrical observations at sea was the mast-head. He had therefore contrived an apparatus for measuring the direction and the velocity of the wind, arranged with a view to such a position, and also with a view to observe accurately the mean effects, and this by a summation of every individual gust, even the lightest. For the most accurate plan of securing data, he had arranged a method of electric registration, which was carried on in the cabins below, while the anemometers were measuring the wind aloft. ('British Association Report,' 1855.)

For the method of discussing the results obtained by means of anemometers, see AËRO-DYNAMICS.

ANEMONIC ACID. A name given to two distinct acids derived from the *Anemone Pulsatilla*, *A. Pratensis*, and *A. Nemorosa*. One of these acids has the formula $C_{30}H_{14}O_{14}$. The formula of the other is doubtful. Neither acid possesses any especial interest.

ANEMONIN ($C_{30}H_{12}O_{12}$?). A white crystalline body found in the water distilled from the *Anemone Pulsatilla*, *A. Pratensis*, and *A. Nemorosa*. It is poisonous, and slightly irritating to the skin. Alkalies transform it into anemonic acid.

ANE'MOSCOPE, an instrument for determining the direction of the wind; usually constructed by connecting with the spindle of a weathercock the hand of a dial on which the points of the compass are marked. [ANEMOMETER.]

ANEROID BAROMETER. [BAROMETER.]

ANE'THUM GRAVEOLENS (DILL)—*Medical Properties of.* This is an umbelliferous plant, native of the south of Europe, Astrakhan, Egypt, and the Cape of Good Hope: it has either migrated or been introduced into Egypt and the Cape. It is also cultivated in England. It was in high repute among the ancients, both as a medicinal and a savoury herb, being mentioned by Hippocrates and Dioscorides (ἄνηθον of the latter); also in the Bible (Matt. xxiii. 23), where, however, it is translated anise. The fruit is the part which is officinal. This consists of a diachenium formed of two flattened mericarps, on the back of which is one, and on the commissure two vittæ, containing the volatile oil, on the presence and quantity of which the peculiar odour and virtues of the fruit depend. The quantity of oil varies much according to the degree of ripeness, the age, and, above all, the place of growth of the fruit. Fruits too ripe, or very long kept, yield less than those gathered before perfect maturity, or very fresh ones. Those raised in England are inferior to those from the south of Europe; the clearer and drier atmosphere of the latter favouring the elaboration of volatile oils. To obtain it, the bruised fruit is submitted to distillation with water: 2 cwt. of good fruits yield 8 lbs. 5 oz. of oil. (Pereira.) The colour is pale yellow; the specific gravity 0·881; the odour peculiar, penetrating, and much disliked by some—hence, the French name of the plant, *Fenouil puant*. The taste is hot, and rather sweetish. It requires 1440 parts of water to dissolve one part of oil. It is very soluble in alcohol and ether. Hence, to form the *aqua anethi* (dill-water), the instructions of the pharmacopœia are rarely complied with, but a portion of the oil is previously dissolved in alcohol and then with sugar diffused through distilled water, by which means a more potent agent is obtained. The oil is sometimes administered by dropping it on sugar, and so forming an oleo-saccharum.

Dill is a carminative agent of considerable power, and in most frequent use, particularly to allay the spasmodic affections of the bowels of infants, and to assist the expulsion of flatus. This practice, though attended with temporary benefit, is in the end hurtful. A much more rational plan is for the nurse who suckles the child to be most careful in her diet, to retire to rest early, and to discharge faithfully all the duties which devolve upon her as a mother. She may take the dill, when troubled with indigestion and flatus, with more safety than the infant, and also with more advantage, as, by promoting the digestion, it augments the quantity of the milk and improves its quality. Like those of several other umbelliferous plants, the seeds are fatal to birds, such as chaffinches.

Dill-water is often made the vehicle of purgative or other medicines to prevent griping. One of the best laxatives for infants is made with equal parts of dill-water and compound decoction of aloes, to which a few drops of aromatic spirit of ammonia may be added. This is much more appropriate than the domestic doses of magnesia and rhubarb, so often given to infants, and which Dr. Reid declared to be the cause of death in one-half the children which died in London under two years of age. The insoluble nature of the woody fibre of rhubarb renders it very irritating to the sensitive stomachs of infants, to whom nothing solid should ever be given. The evils of magnesia are manifold.

A'NEURISM is a Greek word (ἀνευρυσμός), literally signifying 'a widening or extension.' It is now used to signify a tumour, consisting of a preternatural enlargement of an artery. The artery is the only seat of this disease; and any artery of the body may be the subject of it, but it is much more common in some arteries than in others. The corresponding disease in a vein is called a varix. [VARIX.]

An artery is composed of three membranes, which are firmly united, and form the walls of a strong elastic and extensible tube. These membranes are called tunics or coats. In the healthy state of the artery these tunics yield only to a certain extent to the impulse of the blood, so that the tube possesses only a certain diameter; but in a state of disease the impulse of the blood distends these tunics to a preternatural extent, causing that part of the artery which is diseased to swell out into a tumour or bag. The distension of the coats of the artery progressively increasing, they are at last capable of no further stretching, and consequently are torn asunder and burst. But the inner and middle coats of the artery are not as extensible as the external coat; the two former coats are therefore ruptured a considerable time before the latter gives way, in which case the only proper coat of the artery forming the wall of the aneurismal tumour is the external. This coat in its turn getting progressively thinner and thinner as the dilatation goes on, at length bursts like the former; the blood escapes, and life is suddenly extinguished. But sometimes the tumour does not burst even after the rupture of the external coat of the artery; for there is placed around the artery a dense and strong membranous sheath, consisting of what is termed cellular membrane, which sheath is far more extensible than any of the coats of the artery, and it is found that sometimes the aneurismal sac, or the bag-like tumour which the dilated artery forms, consists only of this condensed cellular membrane; all the proper coats of the artery having been rent and destroyed by the progressively distending force. Thus an aneurism may consist simply of the dilatation of the coats of an artery without the rupture of any; or of the dilatation of some with the rupture of others; or of the rupture of all; the bag of the tumour being formed solely by the cellular sheath of the artery.

When the coats of the artery have burst, and this portion of the tube is dilated into a sac, it is evident that this sac is beyond the direct current of the circulation, and that the larger the bag, the farther its contents will be from the influence of the direct current of the blood. The consequence is, that the blood contained in the aneurismal sac undergoes a peculiar change, a modification of the process of coagulation [BLOOD, NAT. HIST. DIV.]; the thinner part of the blood being removed, while a portion of the thicker part, or the fibrin, remains. In this manner there is left upon the internal surface of the sac a stratum of the thicker or fibrous part of the blood. Successive depositions are made of this fibrous part of the blood by which the cavity of the tumour is gradually diminished. At length the sac becomes entirely filled with this substance, which forms for it a firm plug. The deposition of this fibrin is not confined to the aneurismal sac, but is continued into the artery itself, both above and below its dilatation, until it reaches the next important ramification which is given off from the artery, where it stops. In this manner the circulation through the aneurismal portion of the vessel is prevented; the blood is determined into other channels; this portion of the vessel, being no longer of any service in carrying on the circulation, is blocked up, and in this manner is effected a spontaneous cure of the disease.

But this beautiful curative process, though it occasionally happen, is not the usual course. When the external coat or the cellular sheath of the artery are stretched beyond a certain point, it would seem that its vitality is diminished; at length a part of it mortifies or dies; an eschar is formed; the eschar sloughs away; an opening is thus formed in the tumour; the blood rushes out, and the patient dies. This is the mode in which the aneurismal sac bursts when the aneurism is situated on the external part of the body. But if the aneurism be internal the process is different; the tumour becoming thinner and thinner by successive distension, bursts suddenly by a crack or fissure, through which the blood is discharged.

The first symptom which denotes the formation of an aneurism, is the perception of an unusual throbbing in the diseased artery. If the situation of the artery be such that it can be seen or felt, a small tumour is manifest. This tumour, when carefully observed, is found to have a pulsatory motion, this motion, as well as the tumour itself, disappearing when the part is compressed, but instantly reappearing on the removal of the pressure. Commonly, the tumour is without pain, and without any discoloration of the skin. The magnitude of the tumour, whatever its size when first discovered, is steadily progressive; in proportion as it grows larger, the pulsatory motion diminishes, and when it has attained a very considerable size the pulsation is no longer perceptible. The tumour continually enlarging, produces a variety of effects on the parts with which it comes in contact. Some it pushes aside, others it carries with it, and others it destroys. The adjacent muscles, for example, whether they are situated directly over the aneurism, or are at one side of it, are usually stretched, displaced, dwindled, and sometimes entirely confounded with the contiguous parts. The nerves, too, are frequently pushed out of their natural situation; or, if they adhere to the sides of the sac, as they often do, they are necessarily stretched as the tumour enlarges, and this distension of the nervous cords sometimes occasions intense pain. The cartilages and bones, pressed upon by the advancing tumour, gradually disappear, and at length are so completely destroyed that not the slightest vestige of them remains. In general, as long as the tumour is small, it is unattended with pain; but the changes which it produces in other parts, such as the stretching of the nerves and the absorption of the bones, is sometimes attended with intolerable pain, capable of being mitigated by no means hitherto discovered. Death at last puts an end to the pain and the patient together by the bursting of the sac, the approach of the fatal event being clearly indicated by the increasing thinness, softness, and darkness of the tumour.

The importance, in practice, of discriminating between this most dangerous disease and all other tumours is manifest; but the distinction is not always easy, or at any rate is not always made. Many a death has happened in consequence of incisions having been made into aneurisms which were mistaken for abscesses.

There is something in the structure of the larger arteries which predisposes to this disease. Their coats are thinner in relation to the magnitude of the column of blood with which they are filled than the coats of the smaller arteries. The internal are much more subject to aneurism than the external arteries. The curvatures of the arteries are another predisposing cause. The period of life at which aneurism is most frequent is between the ages of thirty and fifty. Sir Astley Cooper, however, states that he has seen the disease in a child only eleven years old, and that he has operated for it with success in a man of eighty-five. It is much more common among males than females. Out of sixty-three cases of this disease, fifty-six were males and only seven females. Aneurism so often follows a sudden violent shock, sustained either by the whole body or by a limb, and more especially by the sudden violent extension of a limb, as apparently to justify the common opinion that external violence is among the most frequent exciting causes of the malady.

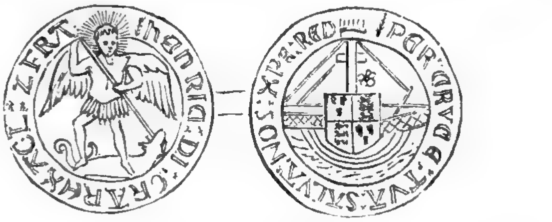
Excepting in the exceedingly rare case in which a spontaneous cure is effected, this disease, when left to itself, uniformly proves fatal by the ultimate rupture of the tumour, in consequence of which the patient expires either instantaneously, from the great and sudden loss of blood, or by degrees, from repeated losses of it.

The cure of aneurism consists in the obliteration of the preternatural cavity of the artery. The obliteration of this cavity is the sole object of the operation which is found to be the only sure and effectual mode of curing the disease. This operation consists in cutting down upon the artery and passing a ligature around it above its dilatation. The immediate effect of the ligature, of course, is to stop the flow of blood into the sac; its ultimate effect is to excite inflammation in the coats of the vessel, by which its sides, brought into close contact by the ligature, permanently adhere together, thus inducing an obliteration of the cavity of the vessel. The success of the operation depends entirely on the completeness of the adhesion of the sides of the vessel, and the consequent obliteration of its cavity. But this adhesion will not take place unless the portion of the artery to which the ligature is applied be in a sound state. If it be diseased, as it almost always is, near the seat of the aneurism, when the process is completed by which the ligature is removed [INFLAMMATION], hæmorrhage takes place, and the patient dies just as if the aneurism had been left to itself. For a long time, surgeons were in the habit of applying the ligature as close as possible to the seat of the aneurism; they laid open the aneurismal sac in its whole extent, and scooped out the blood contained in it. The consequence was that a large deep-seated sore, consisting of parts in an unhealthy state, was formed; and it was necessary to the cure that this sore should suppurate, granulate, and heal,—a process which the constitution was frequently unable to support. Moreover, there was a constant danger that the patient would perish from hæmorrhage, through the want of adhesion of the sides of the artery. The profound knowledge of healthy and of diseased structure, and of the laws of the animal economy by which both are regulated, which John Hunter had acquired from anatomy, suggested to this eminent man a mode of operating, the effect of which, in preserving human life, has placed him high in the rank of the benefactors of his race. This consummate anatomist saw that the reason why death so often followed the common operation, was because a process essential to its success was prevented by the diseased condition of the artery. He observed that while the vessel close to the aneurism was always diseased, at some distance from the aneurism it was in a sound state: it occurred to him, that if the ligature were applied to this distant part, that is, to a sound instead of a diseased portion of the artery, the process necessary to the success of the operation would not be counteracted. But to this there was one capital objection, namely, that it would often be necessary to apply the ligature around the main trunk of an artery, before it gives off its branches, in consequence of which the parts below the ligature would be deprived of their supply of blood, and must therefore mortify. He was well acquainted with the facts of the anastomosis of the blood-vessels. [ANASTOMOSIS.] Reflecting on the number and freedom of the communications of the arterial tubes, he conceived it possible that a limb might receive a sufficient supply of blood to maintain its vitality through the medium of its collateral branches only. For an aneurism in the ham, he therefore boldly cut down upon the main trunk of the artery which supplies the lower extremity, and applied a ligature around it, where it is seated near the middle of the thigh, in the confident expectation that though he thus deprived the limb of the supply of blood which it received through its direct channel, it would not perish. His knowledge of the processes of the animal economy led him to expect that the force of the circulation being thus taken off from the anueurismal sac, the progress of the disease would be stopped; that the sac itself, with all its contents, would be absorbed; that by this means the whole tumour would be spontaneously removed, and that an opening into it would be unnecessary. The most complete success followed this noble experiment; and the sensations which this philosopher experienced on witnessing the event constituted an appropriate reward for the application of profound knowledge to the mitigation of human sufferings. After Hunter followed Abernethy, who treading in the footsteps of his master, for an aneurism of the femoral, placed a ligature around the external iliac artery; lately the internal iliac itself has been taken up, and surgeons have tied arteries of such importance, that they have been themselves astonished at the extent of their success.

Within the last few years the method of curing aneurism by pressure has been revived, and it has been so successful and free from dangerous results that the majority of surgeons have recourse to this method before hazarding the operation of tying the artery. The pressure is applied to the artery at the most accessible point above the aneurism, and in such a manner, as to prevent excessive pain, excoriation, or ulceration of the skin. In order to effect this, compresses of various kinds have been employed—that invented by Dr. Carte is regarded as the most efficient. This operation requires time, and the patient is kept quiet, and submitted to such a course of treatment as is likely to assist generally in obtaining the desired result. Although treatment by pressure has always been occasionally employed, this treatment in modern times was not adopted successfully till 1825, when a successful case occurred in the practice of Mr. Todd, of Dublin. In 1846, twenty-nine cases of femoral and popliteal aneurism had been thus treated, and twenty-five had been cured. Since that time a large number of cases have been treated, both in this country and the United States of America, and the result has been such that no surgeon would now feel himself justified in tying the artery without first having recourse to the method of treatment by pressure, in those cases in which it can be had recourse to.

In some aneurisms, neither operation nor pressure can be applied. In these cases, everything must be done to diminish the current of blood through the aneurismal sac, and facilitate a natural cure. Unfortunately, such cures are rare, but they are frequent enough to warrant the medical practitioner in employing such a course of treatment as is dictated by the nature of the case.

ANGEL (COIN). Dr. Johnson defines it as "a piece of money anciently coined and impressed with an angel, in memory of the observation of Pope Gregory, that the pagan Angle, or English, were so beautiful, that, if they were Christians, they would be Angeli, or Angels." But we must remark that Pope Gregory's observation was made in the 7th century, and the coin called the angel was not struck in England till the middle of the 15th century. The angel was originally a gold coin of France, where it was first coined, at least by that name, in 1340. (See Ducange *voce* Moneta, and Le Blanc, 'Traité Hist. de Monnoyes de France,' 4to Amst. 1692, p. 207.) In France, where it was soon followed by the half and quarter angel, it was always of fine gold, but not always of the same weight. It appears to have been introduced, with its minor divisions, into England by Edward IV., in 1465 (see Leake, pp. 150—164), and was continued as a coin by King Henry VI., when he returned to the throne. We give a representation of the angel of Henry VI. When first introduced, the angel was rated



Angel Coin of Henry VI.

in value at 6*s.* 8*d.*, and being of the same value as the noble, was sometimes called the noble angel. This value was continued at Henry VIII.'s first coinage of gold. In the coinage of that king's latter time, the value was raised to 8*s.*, and so continued through the reign of Edward VI. Queen Mary's angel went for 10*s.*, which value continued to the end of the reign of Charles I., the last of our kings who coined the angel. So base was Henry VIII.'s gold coinage of this money that Stow, in his 'History of London,' says, "I have seen 21*s.* given for an old angel, to gild withal." Queen Elizabeth (according to Nicolson's 'Historical Library,' p. 267, from Fynes Moryson's 'Itin.,' part i. lib. 3, cap. 6), in the forty-third year of her reign (1600—1601), contracted, not only for the coining of angels, and their usual divisions, but for pieces of an angel-and-a-half and three-angels, of the finest angel gold; but it is presumed that the contract for these larger pieces was never completed, as no such coins have ever been seen by our collectors. The usual device on the obverse of the angel was the figure St. Michael standing upon the dragon, and piercing him through the mouth with a spear, the upper end of which terminated in a cross, or cross-crosslet. The reverse of the earlier ones had a ship, with a large cross for a mast, with the royal arms in front. The angels of James I. and Charles I. have the mast of the ship with a main-top, and no cross. The obverse had the king's titles surrounding the device. The reverse, from Edward IV. to Edward VI., bore the inscription 'PER CRVCEM TVAM SALVA NOS CHRISTE REDEMPTOR.' The reverses of the angels of Philip and Mary, Elizabeth, and James I., bore, partly at length and partly abridged, the sentence, 'A DOMINO FACTVM EST ISTVD ET EST MIRABILE [IN OCVLIS NOSTRIS.'] Charles I.'s angel had on the reverse, AMOR POPVLI PRÆSIDIVM REGIS. Folkes (pl. xiii. of his 'Gold Coins') has engraved a piece in silver, struck from the reverse only of a die, intended for an angel by King Charles II., but never coined; with the same inscription on the reverse as his father's angel. The only distinction by which the angels of Henry VI. are known from those of Henry VII. is that in the former the archangel Michael stands with his left foot upon the dragon; in the latter, the angel stands with both feet upon the dragon. In the collection of Lord Pembroke there is a six-angel piece; but it is not certain that it was intended for a coin. The angelets of Edward IV., and to Henry VIII., have on the reverse, O CRVX AVE SPES VNICA. The angelets of Edward VI. have the same inscription on the reverse as the angel.

ANGELIC ACID ($C_{10}H_8O_4$). *Sumbulic acid.*—Found in the roots of several species of Angelica, and obtained also by the action of hydrate of potash upon essence of camomile. It crystallises in large striated colourless prisms, which are anhydrous; they possess a peculiar aromatic odour, and an acid taste. Angelic acid fuses at 113° Fahr. and boils at 374°, distilling without decomposition. It is easily soluble in alcohol, ether, oil of turpentine, and fixed oils. Heated with caustic potash it yields acetate and propionate of potash, evolving hydrogen.

$$\underbrace{C_{10}H_8O_4}_{\text{Angelic acid.}} + 4HO = \underbrace{C_4H_4O_4}_{\text{Acetic acid.}} + \underbrace{C_6H_6O_4}_{\text{Propionic acid.}} + H_2$$

Angelic acid is monobasic, and forms an extensive series of salts which are generally very soluble in water and in alcohol. It also unites with oxide of ethyl, forming angelic ether.

ANGELIC ETHER. [ANGELIC ACID.]

ANGELICINE, a non-azotised vegetable substance found in Angelica root (*Angelica Archangelica*).

ANGER (according to Aristotle, 'Rhetor.' b. ii., c. 2.) *is a desire of revenge, accompanied with pain, on account of an apparent slight improperly offered to a person or some one connected with him.* From this definition it appears, first, that in order to excite the passion of anger it is necessary that a slight should be offered; and secondly, that the slight produces a desire of revenge, which is painful until it is either gratified or assuaged. A slight is an act or forbearance by which a man appears to indicate his opinion that another person is not worthy of notice; and it may be shown both in active and passive conduct; actively, as when a person insults, reviles, ridicules and banters, or annoys, vexes, and teases another: passively, as when a person omits the marks of attention and respect which an inferior owes to a superior, or an equal to an equal, or when he treats another with contempt. In the cases of abuse, insult, and unseemly or misplaced ridicule, as well as where there is a scornful indifference or want of respectful behaviour, the pain is caused by the undue assumption by which an equal appears to make himself a superior, and an inferior an equal. Hence it is (as an ancient historian has remarked) that men care more for insult than injury; as the one seems to be the aggression of an equal, for his own profit; the other to be the insolence of a superior, arising from spite or mere wantonness. On a similar reason was founded the advice of Bernadotte to Louis XVIII., that France was to be governed with an *iron hand*, and a *velvet glove*: a remark capable of a much wider extension. In the cases of annoyance and vexation, the pain of the person angered is caused by the feeling that the object of the other party is purely to give pain, without any advantage accruing to himself.

The pain excited by the slight is instantly followed by a desire of *revenge*. The desire of revenge is not a general desire that ill may come to the person offering the slight, but a desire of personally paining him, so that he may know by whom the pain is inflicted, and the person angered may have the gratification of being himself the executioner of his own retribution. The satisfaction of the desire of vengeance is always pleasurable, and in brutal and uncultivated minds is attended with all the marks of the most triumphant exultation. So strong indeed is the temptation of gratifying this craving after retaliation, when the means of indulging it are in our power, and so great the difficulty of foregoing the pleasure which it affords, that Shakspere enumerates among the rare instances of female perfection—

> "She who being angered, her revenge being nigh,
> Bids her wrong stop, and her displeasure fly."

No angry person, however, would feel his desire of revenge satisfied by learning that the object of his anger has suffered some grievous calamity, as that he has lost a near relation or a large sum of money; he wishes that the pain should be inflicted *in return* for the slight shown to him, and by *his own* agency. Anger, therefore, is different from hatred; the one is a passion which is commonly extinguished by the lapse of time, even if the desire of vengeance is not satisfied; the other is a settled habit of the mind which never varies: the one is attended with pain, the other is without pain. Anger is always personal, and is felt only towards individuals: hatred is often general, and embraces not only individuals, but whole classes, as murderers, tyrants, heretics, &c. There are even *national* hatreds, and misanthropy is a hatred of the *whole human race*. Anger is often satisfied with a slight infliction of pain, whereas hatred desires nothing less than the extinction of the persons hated; hence pity is consistent with anger, but never with hatred. Anger seeks to inflict pain; hatred desires to do harm. Anger requires a personal retaliation, hatred is pleased that harm should come to the person hated, from whatever quarter, and by whatever means. (See Aristot. 'Rhet.,' b. 2. c. 4.)

As anger is a bad passion, the object of which is the infliction of pain, it ought to be restrained; and one of the most important parts of moral discipline is the proper regulation of the desire of revenge which characterises it. The proper government of this passion consists not in altogether suppressing it, which is indeed impossible, as every person must feel pained at an undeserved slight, but in repressing the desire of vengeance to which that pain gives rise. It is a rule, to which every exception should be questioned with the utmost jealousy, that in a political society all vengeance for vengeance sake is immoral. This, however, does not prevent a person from showing *his displeasure* at an improper slight: so that the reproof be given without animosity, and arise from a desire of preventing future affronts or vexation, not of satiating a thirst for revenge.

Although anger is a bad passion, and in a state of civil society its effects are much oftener hurtful than beneficial, its *use* (or, as it is sometimes said, its *final cause*) is not the less obvious. In a state of nature, before the institution of government, if instead of men being prompted by the constant and violent influence of a passion to retaliate harm for harm, the retribution of wrongs had been left to the irregular operation of cool reason, it may be doubted whether the collision of interest and the mutual resistance which arose from each man being the avenger of his own cause, and which were the origin of political government, would ever have existed. Hence revenge (as Lord Bacon has said) is a sort of wild justice; that is, in a society where there is no administration of law, it takes the place of legal justice: and it is better that wrongs should be avenged than that they should be done with entire impunity. In the barbarous states of society which have prevailed at different times in Arabia, Greece, Germany, Scotland, and other countries, the imperfect security of person which existed was owing chiefly to the duty of revenge imposed by traditionary feelings and opinions on the family of a murdered person. But when the exercise of sovereign political power is once firmly established, together with an efficient administration of law by regular judicatories, the use of revenge, as an instrument for the suppression of wrongs, has ceased, and it must give place to a far better substitute. The good, says the French proverb, is the enemy of the better; and on this principle, a political society, both in its legal and moral code, must discard that instrument to which it may, indeed, in great measure, owe its *existence*, but which is incompatible with its *continuance* in a state of happiness and tranquillity. The private retaliation of wrongs is the scaffolding by means of which the structure of civil society was erected, but which disfigures its beauty and impairs its utility when completed. [PUNISHMENT.]

ANGI'NA PE'CTORIS, literally, "a contraction or tightening of the chest," a disease so named from the anguish felt in the chest. This disease is characterised by a sudden attack of severe pain in the lower part of the chest, commonly inclining to the left side; the pain is sometimes so severe, that the patient feels as though he must die: the pain generally extends to the left arm, and occasionally also to the right: it is often attended with a sensation of fainting or of suffocation, and with palpitation of the heart; but frequently these latter symptoms are absent; the pulse is commonly quick, weak, irregular, or intermittent, though sometimes it is little affected; the countenance is commonly pallid, and the expression anxious and depressed. This attack comes on in paroxysms, which last from a few minutes to half an hour and more. There is no regular interval between the paroxysms, and no distinct warning of their return. They usually come quite suddenly, from slight causes, and often when no cause can be assigned. The health at first is tolerably good during the intervals, but in the progress of the disease a great variety of uneasy sensations distress the patient even when the paroxysm is absent, chiefly those which indicate a disordered state of the digestive and respiratory organs.

Much investigation has been instituted to ascertain the seat and nature of this disease; and although physicians are not yet unanimous in their opinion in regard to either, yet sufficient evidence has been accumulated to determine both with a high degree of probability. It seems upon the whole to be established that it is primitively a nervous affection, and that the nerves in fault are those which supply the lungs and heart,—the lungs, in consequence of the disease of its nerves, being unable perfectly to decarbonise the blood, and the heart, in consequence of the disease of its nerves, not being duly nourished, and consequently not being able to carry on the circulation with the requisite energy and regularity. On inspection of the organs after death of those who perish by this disease, in the immense majority of cases appreciable disease is discoverable both in the lungs and in the heart, but more especially in the latter. The most frequent morbid appearances in the heart are ossification of the coronary arteries (the nutrient arteries of the organ); ossification of the valves of the heart; preternatural accumulation of fat on its external surface; enlargement of its cavities; and, above all, change of structure in its muscular substance, which becomes pallid, soft, flabby, thin, and easily torn. This change in the muscular substance of the heart is by far the most constant morbid appearance; but even this, as well as the other organic changes, must be considered as the effect rather than the cause of the disease, in whatever degree these organic changes may be the cause of death.

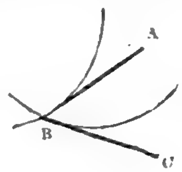
Angina pectoris is most frequent at the meridian of life and beyond it; it may occur in adolescence, but it is very rare at that period. It is much more frequent in the male than in the female. Out of one hundred cases, seventy were upwards of fifty years of age, and seventy-nine were males. It is remarkably under the influence of mental causes, if it be not in the first instance induced by them. When it has once occurred, a paroxysm is readily produced by any emotion, whether of a pleasurable or a painful nature, but more especially by the latter. Anxiety of mind, any depressing passion, or anger, places a person subject to this disease in the most imminent danger. Many persons have died suddenly, instantaneously, under the influence of such emotions. There is conceived to be a close connection between this disease and gout. Without doubt it is very often found in persons who are subject to gout, and the less the gout affects the extremities, in its regular and decided form, the more frequently and severely such persons suffer from angina pectoris.

It is of the nature of this disease to proceed progressively from bad to worse. At first it is a temporary evil of short duration, recurring perhaps only at distant intervals; but if it be neglected, the intervals become shorter and shorter, and the paroxysms more and more severe. Complete success often attends the early, active, and judicious treatment of it. This, therefore, is eminently one of those diseases, the first accession of which should excite serious alarm, and induce every one to adopt without delay, and with the greatest regularity, the means best fitted to prevent the recurrence of it.

Those means are, in the paroxysm, absolute rest. The paroxysm often comes on in walking or during some bodily exertion: the patient has the feeling that the continuance of such exertion would prove instantaneously fatal; and it is really highly dangerous. Unless in very severe cases, the paroxysm usually goes off spontaneously, in a few minutes, on sitting perfectly still, or, which is often better, on lying down. If the pain do not quickly subside, vigorous friction with a stimulating liniment should be applied over the whole chest, and the patient should instantly take some warm antispasmodic and stimulant medicine, such as two ounces of the camphor julep, with a dram of ether or of the aromatic spirit of ammonia. But much more active measures may be necessary; and this is a disease so serious in its nature, and requiring so much delicacy and skill in the management of it, that the patient ought to place himself under the best medical guidance he can procure as quickly as possible. It is during the interval that the most effectual treatment must be employed. It is impossible to discuss here the remedies which the physician should resort to, the reasons which should determine his choice, and the different states which should modify the treatment in adaptation to individual cases. But it is very important to state, that angina pectoris is one of those diseases in which the concurrence of the patient with the efforts of the physician is indispensable. Unless the patient resolve and firmly adhere to his resolution strictly to conform to the plan prescribed in diet, in exercise, in every locomotive movement, in sleep, temperature, and medicine, but above all in the regulation of the mind, the physician can do but very little for him.

ANGLE OF CONTINGENCE, or CONTACT, the opening made by a curve and its tangent. [CURVATURE.]

ANGLE (CURVILINEAR), the rectilinear angle made by the tangents of two curves at the point where they meet, as A B C.



ANGLE (HORARY), the angle formed with the meridian of any place by a great circle, which passes through a star and the pole.

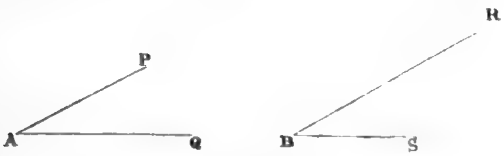
ANGLE OF INCIDENCE, REFLECTION, REFRACTION, ELONGATION, ELEVATION, THE VERTICAL.—See these several terms.

ANGLE, PLANE, SPHERICAL, SOLID, PARALLACTIC.—See these terms.

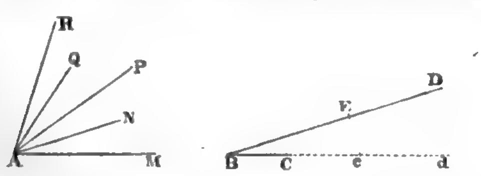
ANGLE OF POSITION, usually the curvilinear angle made by two great circles drawn through a star to the poles of the ecliptic and equator. It may be used to signify the angle made by lines drawn from any point under consideration to any two points which are used in determining the *position* of others.

ANGLE (RECTILINEAR), from the Latin word *angulus*, of the same signification. The notion (for it can hardly be called definition) is, the *opening* made by two straight lines which cut one another. The term *inclination* is also used synonymously with angle; thus, the angle or opening of two lines is called their inclination to one another.

To investigate a more precise definition for this word, we must recollect that any species of relation is entitled to the term *magnitude*, and becomes the object of arithmetic or geometry, so soon as it can be shown that the notion implied in one or other of the words equal, greater, or less, is always derivable from the consideration of two such relations. Take the two angles or openings made at the points A and B by the straight lines A P and A Q at A, and by B R and B S at B, and transfer the first figure to the second, so that the point A shall fall upon B, and the straight line A Q upon B S; or rather, let as much of A Q as is equal to B S fall upon B S, and let the remainder of A Q form a continuation of B S: also let A P and B R be made to lie

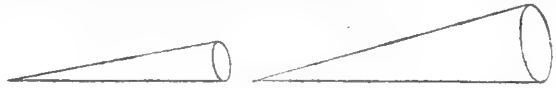


upon the same side of B S. We have now no longer any control over the position of A P with respect to A Q, since the first figure is not to undergo any change except that of simple removal into another position. If, after A Q has been placed upon B S, A P then fall upon B R, the two openings or angles at A and B are the same. If A P, in its new position, fall between B S and B R, the opening or angle at A is less than that at B; and if A P fall further from B S than B R does, the angle at A is greater than that at B. The angle at A is called the angle P A Q, and that at B, the angle R B S. Hence the notion of one angle being twice or three times, &c., as great as another may be fixed. For example,



the angle M A P being made up of the two M A N and N A P, each of which is equal to the angle D B C, is twice D B C; the angle Q A M is three times D B C; R A M is four times D B C; and so on. Similarly, the angle D B C is one-half of P A M, one-third of Q A M, &c. The angle made by two lines does not depend upon the length of these lines; if a part D E be cut off from B D, the angle is not altered, that is, the angle E B C is the same as D B C. If B e and B d be respectively equal to B E and B D, and if B C e d turn round B, the same *quantity of turning* which brings B e into the position B E, will bring B d into that of B D.

When we cast our eyes on two angles, the sides containing which are nearly equal in both, we judge of their comparative magnitude by the spaces which are included between the lines. But this is is not a notion capable of being rendered rigorous, because one boundary of the space is indefinite. Nevertheless we may correct this method of judging, and produce a precise idea of an angle, *if* we admit the propriety of comparing with one another spaces which are absolutely infinite in extent. The longer the lines are, the more nearly is the preceding notion absolutely correct, because the space at and near the



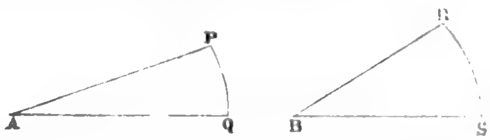
mouth of the angle, which for want of a definite boundary is doubtful as to whether it is or is not to be considered a part of the angular opening, becomes less and less with respect to that about which there is no doubt. If then we suppose the lines which contain the angle to be produced without end, the infinite spaces so imagined will be correctly in the same proportion to one another as the angles. The objection to introducing this into geometry is the real or supposed want of rigour in the comparison of unbounded spaces. [INFINITE.] It must be remarked, however, that the disputed theory of parallels follows immediately and rigorously from the preceding (see 'Library of Useful Knowledge,' Study of Mathematics, pp. 77, 78; and Lacroix, 'Elémens de Géométrie,' p. 23, note), and it is therefore in the choice of every person to decide for himself whether he will *add* the words in italics to the first of the two following axioms, and *prove* the second, or *omit* the words in italics, and *assume* the second.

1. Two spaces, *whether of finite or infinite extent*, are equal when the one can be placed upon the other, so that the two shall coincide in all their parts.

2. Through a given point, not more than one parallel can be drawn to a given straight line.

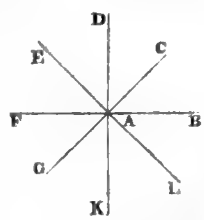
In order to bound the preceding spaces, and compare angles by means of spaces or lines, it is necessary to draw arcs of circles having equal radii through the two points.

Let P Q and R S be arcs of circles having the equal radii A Q, B S.



Then the angles P A Q and R B S are in the same proportion as the spaces (called *sectors*) P A Q, and R B S, and also as the lengths of the arcs P Q and R S. This proposition, which is Euclid, vi. 33, is not so far from first principles as its position would appear to indicate. For the fifth book, on proportion, is entirely independent of, and might be considered as antecedent to, the first four books: if this were supposed, the preceding proposition might be easily made to follow book i. 23, or even i. 8. We might even place it immediately after the doctrine of proportion, by a proof founded on simple superposition, provided we assume (what is tacitly assumed in various parts of the first book of the elements, i. 4, for example) that an angle may be conceived equal to another angle before we know how to construct equal angles.

If a line setting out from A B be conceived to revolve round the point A, it will in every position form two openings or angles with its original position A B. For example, in the position A C, A B and A C will form the smaller angle B A C, and the larger angle made up of the angles C A F, F A K, and K A B. Only the former of these is usually considered in geometry, but the latter is frequently used in analysis. When half a revolution has been made, and A B has come to A F, at first sight we might say there was no angle formed; but on looking at the preceding position A E, we see that the opening of B A and A F is greater than that of B A and A E. The half of this opening B A F, that is, B A D, is called a right angle. A whole revolution makes A B pass through four right angles, and, in analysis, if we wish to point out that the line A C is supposed to have made a complete revolution, and to have come into the position B A C for the second time, the angle made with A B is said to be



4 right angles + B A C

An *angle* is the opening of two lines; *rectilinear*, of two straight lines; *curvilinear*, of two curves; *mixtilinear*, of a straight line and a curve. But, in truth, angle always means rectilinear angle; and when a curve enters, its tangent is the straight line which is used in determining the angle.

A *right* angle is half the opening of a straight line and its continuation;

an *acute* angle is that which is less than a right angle; an *obtuse* angle is that which lies between one and two right angles. *Complemental* angles are two which together make a right angle; *supplemental* angles are two which together make two right angles. Two lines which meet and make a pair of angles, one less than two right angles, are called *salient;* the other greater than two right angles, are called *re-entrant*, or *re-entering*. None but salient angles are mentioned by Euclid. For salient and re-entering (which are borrowed from fortification), *direct* and *retroflected* have sometimes been used.

The angles which two lines make with the same part of a third, on opposite sides of it, are called *alternate*. Two lines which cross one another make two pair of *vertically opposite* angles. The angles made by adjacent sides of a figure are called *internal;* those made by any sides with adjacent sides produced are *external*. When the angular point is the centre or on the circumference of a circle, the *angle* is said to be *at* the centre, or *at* the circumference. Beginners often confound the angle with the angular point.

The angle of *contingence* or of *contact* is an old notion of the opening made by two curves, or a curve and a line, which touch. In modern mathematics, when a curve is supposed to be composed of infinitely small rectilinear elements, the infinitely small acute angle made by one element with the production of the next does duty for this old angle of contingence.

A *spherical* angle is made by two circles (usually great circles) of a sphere. When the circles meet at the pole of the equator, and one of them is the meridian, the angle is an *horary* or *hour-angle;* and when neither is the meridian, the angle is frequently called *horary*. The *angle of position* of a star is that made by the circles drawn to it from the poles of the equator and ecliptic. The angle of *elevation* is the angle made by a line drawn from the eye to any object with the horizontal line which is in the same vertical plane as the first line; but when the object is below the horizon, the term is angle of *depression*. When lines are drawn from two points to a third, those two points, and also the line joining them, are said to *subtend* the angle which is made at the third point. The angle which two objects subtend at the eye is their angle of *elongation*. The *angle of the vertical* is a name given to the angle which a line drawn to the spectator's zenith makes with his radius of the earth produced: it is taken as nothing when the earth is supposed to be a perfect sphere. Angular terms, such as right ascension, longitude, &c., with which the word angle is not usually coupled, are not considered here. The *parallactic* angle is simply the PARALLAX.

When one line falls upon another, the angle of *incidence* is the acute angle which the incident line makes with the perpendicular to the other. When the incident line is thrown off again on the same side as that from which it came, the acute angle made with the perpendicular is called the angle of *reflexion;* when on the opposite side, the angle of *refraction*. These terms are nearly confined to optics.

A *dihedral* angle is the opening made by two planes. It is measured by a rectilinear angle, namely, that made by two lines drawn in the two planes perpendicular to their common intersection. But the rectilinear measure is not the same thing as the dihedral angle, though the two are often confounded. We might just as well say that the pressure of the air is the same thing as the number of inches in the barometrical column of mercury.

A *solid* angle is said to exist when three or more straight lines, not in the same plane, meet at a point. It is a complex idea, and the best notion of it as a magnitude is derived from considering it as measured by the area of the spherical triangle which subtends it.

For the most important properties of angles see TRIANGLE; PARALLEL; POLYGON; TRIGONOMETRY.

The methods of measuring an angle, of which we think it necessary to take notice, are three in number. The first is the one universally employed in *theoretical* investigations, and is as follows:—in the last figure but one, the number which expresses what proportion the arc P Q is of the radius, is the number chosen to represent the angle. It is shown in geometry that if any number of arcs be drawn with the centre A, subtending the same angle P A Q, what part soever any one of them is of its radius, the same part is any other of *its* radius; that is, whatever circle may be chosen, the preceding measure gives the same number for the same angle. For example, if the arc P Q be equal to the radius, the angle P A Q is the angle 1. If P Q be two-thirds of the radius, the angle P A Q is the angle $\frac{2}{3}$. The unit of this measure is therefore the angle whose arc is equal in length to its radius. It is customary to say that an angle or arc (for the terms are frequently confounded) thus measured, is given in parts of the radius; but this expression does not convey much meaning, and we cannot propose any better, unless it might be judged proper to say it is measured in *theoretical* units, meaning thereby, in the units which are always employed in pure theory; or in *arcual* units, derived from use of the arc. The *theoretical* or *arcual* unit would then be the angle subtended by the arc which is equal to its radius.

The semi-circumference of a circle contains its radius,

3·14159, 26535, 89793, 23846

times, very nearly. This is then the number of theoretical units contained in two right angles. The right angle is therefore

1·57079, 63267, 94896, 61923,

and the following are the angles of one degree, one minute, and one second, to which we shall presently come:

·01745, 32925, 19943, 29577 degree
·00029, 08882, 08665, 72160 minute
·00000, 48481, 36811, 09536 second.

In the second measure, in which angles are said to be measured in *space* (the word space being here opposed to *time*, as we shall see, and not to *length*), the whole angle traced out in one revolution, equal to four right angles, is divided into 360 equal parts, each of which is called one *degree*, and marked thus, 1°. Each degree is divided into 60 equal parts, each called one *minute* (1′), and each minute into 60 equal parts, each called one *second* (1″). Formerly, the second was divided into 60 equal parts called *thirds*, and so on; but it is now usual to use the tenths, hundredths, &c., of seconds. The present table therefore stands thus:

A whole revolution = 360° = 21,600′ = 1296,000″
A right angle = 90° = 5,400′ = 324,000″

Degrees.	Minutes.	Seconds.
1	60	3600
	1	60

To convert an angle from *theoretical units* into *degrees, &c., of space*, observe that the last-mentioned unit is

206264″·806247096355 in seconds
3437′·746770784939 in minutes
57°·295779513082 in degrees

and multiply the number which expresses the angle in theoretical units by the one among the preceding numbers which has the same denomination as that to which the angle is to be reduced. As many decimals may be taken as shall be considered necessary. The following table however will be found more convenient:

	Degrees.	Minutes.	Seconds.
1	·05729578	·03437747	·020626481
2	·11459156	·06875494	·041252961
3	·17188734	·10313240	·061879442
4	·22918312	·13750987	·082505922
5	·28647890	·17188734	·103132403
6	·34377468	·20626481	·123758884
7	·40107046	·24064227	·144385364
8	·45836624	·27501974	·165011845
9	·51566202	·30939721	·185638325

EXAMPLE. What number of minutes and decimals of minutes does the angle contain which expressed in theoretical units is 1·7906?

From the minutes' column take out the rows opposite to 1, 7, 9, and 6; write them so that the first figure of each shall fall under its corresponding figure in 1·7906, and add, but take only so many out of each row as will serve to fill up the places under the first row, increasing the last figure of each broken row by 1, when the first neglected figure is 5 or upwards:

1·7906
―――――
03437747
2406423
309397
2063
―――――
06155630

Place the decimal point *three* places off the unit's column for *degrees*, *five* for *minutes*, and *seven* for *seconds*. This gives 6155′·630, since the present calculation is made for minutes. Further to illustrate the placing of the decimal point, let the angle theoretically expressed be ·096, to be turned into degrees and decimals of degrees, and afterwards to seconds and decimals of seconds:

0· 096
51566202
3437747
―――――
0 055003949

Bring down the preliminary cyphers, and *then* cut off three places, which gives 5°·5003949. Again for the seconds:

0· 096
185638325
12375888
―――――
0 0198014213

Cut off *seven* places, which gives 19801″·4213.

Given an arc of a circle and the radius to determine the degrees, minutes, or seconds in the angle at the centre; divide the arc by the radius, and proceed with the quotient as above.

For the converse problem, given the degrees, minutes, and seconds in an angle, to express the same in theoretical units, the following table is given :—

	Degrees.	Minutes.	Seconds.
1	·01745329	·00029089	·00000485
2	·03490659	·00058178	·00000970
3	·05235988	·00087266	·00001454
4	·06981317	·00116355	·00001939
5	·08726646	·00145444	·00002424
6	·10471976	·00174533	·00002909
7	·12217305	·00203622	·00003393
8	·13962634	·00232710	·00003879
9	·15707963	·00261799	·00004363

EXAMPLE.—It is required to express in theoretical units the angle 89° 52′ 34″. Take out the row corresponding to each figure from the column having the same denomination, taking seven places only for a unit's figure, and the whole eight places for the tens, increasing the last figure when necessary, as before: add and make seven decimal places.

For 80°	1·3962634
.. 9°	·1570796
.. 50′	0·0145444
.. 2′	·0005818
.. 30″	0·0001454
.. 4″	·0000194
	1·5686340

and the answer is 1·5686340.

Given any angle and a radius, required the circular arc subtended by that angle; proceed as above, and then multiply by the radius. Thus, to a radius of 100 feet, the arc which subtends an angle of 89° 52′ 34″ is

$$1 \cdot 5686340 \times 100 \text{ or } 156 \cdot 86340 \text{ feet.}$$

In the attempt to effect a universal change of weights and measures, which followed the French Revolution, the circle was divided into 400 degrees, each degree into 100 minutes, each minute into 100 seconds, and so on. This innovation obtained only a partial introduction, and is now almost entirely abandoned. When used, it is customary in this country to distinguish the French degrees by the name of GRADES, and to denote one grade by 1°, or $1^{gr.}$ The convenience of this method, from its close affinity with the decimal system, is certainly great: for example, grades and decimals of grades, such as $12^{gr.}$ 1329 are converted into grades, minutes, and seconds, by mere separation of the figures: thus, $12^{gr.}$ 13′ 29″.

It is not necessary to give complete tables of reduction from the new French to the ancient system, as they would so seldom be useful; the following is all that is necessary :—

1^{gr} is 0°·9 or 54′ or 3240″
1′ „ 0 ·009 „ 0′·54 „ 32″·4
1″ „ 0 ·00009 „ 0′·0054 „ 0″·324

The third method of measuring angles, in which they are said to be measured in *time*, is confined to astronomy, and is derived from the complete apparent revolution of the heavens which takes place in 24 hours. That is, if a line revolve round a point at the rate of a whole revolution in 24 hours, or a right angle in 6 hours, the times of moving through different angles are made the measures of their comparative magnitudes. Thus 4^h 32^m 60^s is the angle moved through in 4 hours, 32 minutes, and 60 seconds. The following tables are useful in turning angles measured in degrees, &c., of space into the corresponding measures in time, and the converse:

TIME INTO SPACE.					SPACE INTO TIME.				
Hours.	°	Min. / Sec.	° / ′	′ / ″	° / ′	h. / m.	m. / s.	″	s.
1	15	1	0	15	1	0	4	1	0·067
2	30	2	0	30	2	0	8	2	0·133
3	45	3	0	45	3	0	12	3	0·200
4	60	4	1	0	4	0	16	4	0·267
5	75	5	1	15	5	0	20	5	0·333
6	90	6	1	30	6	0	24	6	0·400
7	105	7	1	45	7	0	28	7	0·467
8	120	8	2	0	8	0	32	8	0·533
9	135	9	2	15	9	0	36	9	0·600
10	150	10	2	30	10	0	40	10	0·667
11	165	20	5	0	20	1	20	20	1·333
12	180	30	7	30	30	2	0	30	2·000
13	195	40	10	0	40	2	40	40	2·667
&c.	&c.	50	12	30	50	3	20	50	3·333
					60	4	0		
					70	4	40		
					80	5	20		
					90	6	0		
					100	6	40		
					200	13	20		
					300	20	0		

In these tables, where there are two headings, either the upper or under of both must be used. The following are examples:

To turn 18^h 11^m $35^s·3$ into degrees, &c., of space. From the first table:

10^h	is	150° 0′ 0″
8^h	„	120 0 0
10^m	„	2 30 0
1^m	„	15 0
30^s	„	7 30
5	„	1 15
$0^s·3$	„	4·5
18^h 11^m $35^s·3$	is	272°· 53′ 49″·5

To turn 97° 54′ 23″ into hours, &c. From the second table,

90°	is	6^h 0^m 0^s
7°	„	28 0
50′	„	3 20
4′	„	16
20″	„	1·333
3″	„	0·200
97° 54′ 23″	is	6^h 31^m $37^s·533$

In astronomy 30° is sometimes called a sign, in allusion to the arc of the ecliptic, through which one of the signs of the zodiac extends: Thus $2^{s·}$ 3° 4′ 12″ means 63° 4′ 12″.

The *angle* is distinguished from all other magnitudes whatsoever in a very remarkable way. It is the only magnitude which is a function of a number, and of which a number is a function. Let any one single magnitude, not angle, say a length, be presented: without reference to other magnitude, it is impossible to assign a number with which that length is necessarily connected, so that by merely giving the length, the number is deducible. But an angle, when given, determines ratios of lines, and so determines number. To one angle there is but one ratio of arc to radius, one sine, one cosine, &c., and all these are numbers. Consequently, a relation may exist between *one* angle and numbers; but the idea of a relation between one length and numbers is absurd.

ANGLE, TRISECTION OF. [TRISECTION.]

ANHYDRIDES, or ANHYDROUS ACIDS. A class of chemical compounds of great theoretical interest. They are represented both amongst organic and inorganic bodies, but it is especially the organic anhydrides discovered by Gerhardt, which, in conjunction with Williamson's compound ethers, have exercised so profound an influence upon the development of theoretical chemistry. The anhydrides bear the same relation to the hydrated acids as the ethers bear to the alcohols, and they may be regarded as formed from the hydrated acids, by the substitution in the latter, of a second equivalent of a negative radical for the remaining single equivalent of hydrogen, a transformation which will be more readily understood by reference to the following comparison:

Vinic alcohol.	Vinic ether.
$\left.\begin{matrix}(C_4H_5)\\ H\end{matrix}\right\}O_2$	$\left.\begin{matrix}(C_4H_5)\\ (C_4H_5)\end{matrix}\right\}O_2$
Acetic acid.	Acetic anhydride.
$\left.\begin{matrix}(C_4H_3O_2)\\ H\end{matrix}\right\}O_2$	$\left.\begin{matrix}(C_4H_3O_2)\\ (C_4H_3O_2)\end{matrix}\right\}O_2$

The organic anhydrides are best obtained by acting upon the potash salt of an organic acid by the chloride of a negative radical. Thus acetic anhydride is produced by distilling a mixture of solid and dry acetate of potash with chloride of othyl. The following equation represents the nature of the reaction:

$$\underset{\text{Acetate of potash.}}{\left.\begin{matrix}(C_4H_3O_2)\\ K\end{matrix}\right\}O_2} + \underset{\text{Cloride of othyl.}}{\left.\begin{matrix}(C_4H_3O_2)\\ Cl\end{matrix}\right\}} = \underset{\text{Anhydrous acetic acid.}}{\left.\begin{matrix}(C_4H_3O_2)\\ (C_4H_3O_2)\end{matrix}\right\}O_2} + \underset{\text{Chloride of potassium.}}{\left.\begin{matrix}K\\ Cl\end{matrix}\right\}}$$

The anhydrides are neutral bodies, generally liquid, although some are solid. In contact with water they are gradually re-converted into hydrated acids. Acted upon by ammonia they give either neutral amides or ammoniacal salts of amidated acids. The anhydrides may either contain two equivalents of the same negative radical, as acetic anhydride, or they may be formed by the juxtaposition of two different negative radicals as, for instance, aceto-benzoic anhydride, which contains both othyl ($C_4H_3O_2$) and benzoyl ($C_{14}H_5O_2$).

The organic anhydrides may be divided into two classes, namely, 1st, The anhydrides of monobasic acids; and 2nd, the anhydrides of bibasic acids. A third class would be formed by the anhydrides of the tribasic acids, but no organic compound of this class has yet been formed. The following is a list of the principal anhydrides hitherto obtained:

I. ANHYDRIDES OF MONOBASIC ACIDS.

Acetic anhydride	$\left.\begin{matrix}C_4H_3O_2\\ C_4H_3O_2\end{matrix}\right\}O_2$
Butyric	$\left.\begin{matrix}C_8H_7O_2\\ C_8H_7O_2\end{matrix}\right\}O_2$
Valeric	$\left.\begin{matrix}C_{10}H_9O_2\\ C_{10}H_9O_2\end{matrix}\right\}O_2$

Pelargonic	$\left.\begin{matrix}C_{18}H_{17}O_3\\C_{18}H_{17}O_3\end{matrix}\right\}O_2$
Angelic	$\left.\begin{matrix}C_{10}H_7O_3\\C_{10}H_7O_3\end{matrix}\right\}O_2$
Benzoic	$\left.\begin{matrix}C_{14}H_5O_3\\C_{14}H_5O_3\end{matrix}\right\}O_2$
Cuminic	$\left.\begin{matrix}C_{20}H_{11}O_3\\C_{20}H_{11}O_3\end{matrix}\right\}O_2$
Cinnamic	$\left.\begin{matrix}C_{18}H_7O_3\\C_{18}H_7O_3\end{matrix}\right\}O_2$
Salycilic	$\left.\begin{matrix}C_{14}H_5O_3\\C_{14}H_5O_3\end{matrix}\right\}O_2$
Aceto-benzoic	$\left.\begin{matrix}C_4H_3O_3\\C_{14}H_5O_3\end{matrix}\right\}O_2$
Cumino-œnanthylic	$\left.\begin{matrix}C_{20}H_{11}O_3\\C_{20}H_{11}O_3\end{matrix}\right\}O_2$
Valeroangelic	$\left.\begin{matrix}C_{10}H_9O_3\\C_{10}H_7O_3\end{matrix}\right\}O_2$

II. Anhydrides of Bibasic Acids.

Succinic anhydride	$\left.\begin{matrix}C_4H_2O_2\\C_4H_2O_2\end{matrix}\right\}O_2$
Lactic	$\left.\begin{matrix}C_6H_5O_2\\C_6H_5O_2\end{matrix}\right\}O_2$
Phtalic	$\left.\begin{matrix}C_8H_2O_2\\C_8H_2O_2\end{matrix}\right\}O_2$
Camphoric	$\left.\begin{matrix}C_{10}H_7O_2\\C_{10}H_7O_2\end{matrix}\right\}O_2$
Fumaric, or Maleic	$\left.\begin{matrix}C_4H\ O_2\\C_4H\ O_2\end{matrix}\right\}O_2$
Tartaric	$\left.\begin{matrix}C_4H_2O_4\\C_4H_2O_4\end{matrix}\right\}O_2$
Pyrocitric	$\left.\begin{matrix}C_5H_2O_2\\C_5H_2O_2\end{matrix}\right\}O_2$

ANHYDROUS ACETIC ACID. [Anhydrides.]

ANHYDROUS ACIDS. [Anhydrides.]

ANHYDROUS ANGELIC ACID. [Anhydrides.]

ANHYDROUS ACETO-BENZOIC ACID. [Anhydrides.]

ANILES. A name applied to certain organic chemical compounds, forming a sub-class of amides. They contain one equivalent of aniline, *plus* one equivalent of a bibasic acid, *minus* four equivalents of water. [Anilides.]

ANILIC ACID, *Indigotic acid, Nitro-salicylic acid* ($C_{14}H_5(NO_4)O_6$ + 2aq.). This acid is one of the numerous substances formed by the decomposition of indigo. It is procured by the long continued action of weak nitric acid on that substance. It is also formed by treating salicylic acid with fuming nitric acid. It is identical with nitro-salicylic acid. Anilic acid is a solid, fusible, and volatile substance, forming fine yellowish-white prisms, which shrink in drying. It combines with bases forming anilates. The anilate of the oxide of methyl may be obtained by the action of nitric acid on the oil of gaultheria, which is a salicylate of the oxide of methyl.

The solution of anilic acid is coloured blood red by persalts of iron. Concentrated nitric acid converts it into picric acid.

ANILIDATED ACIDS. [Anilides.]

ANILIDES. A sub-class of amides, which might also be termed *phenyl* amides, formed with aniline instead of ammonia. Gerhardt gives the following classification of the anilides:

Anilides corresponding to neutral salts.	*Anilides:* 1 atom aniline + 1 atom of a monobasic acid — 2HO.
	Dianilides: 2 atoms analine + 1 atom of a bibasic acid — 4HO.
Anilides corresponding to acid salts.	*Anilidated Acids:* 1 atom aniline + 1 atom of bibasic acid — 2 HO.
	Aniles: 1 atom aniline + 1 atom of a bibasic acid — 4HO.

ANILINE ($C_{12}H_7N$)—*Kyanol, Crystalline, Phenylamine, Phenamide, Benzidam.* Hofmann has demonstrated that the base obtained by Unverdorben, under the name of *crystalline*, from the products of the distillation of animal matter or coal tar, is identical with aniline. The same distinguished chemist has added largely to our knowledge of this substance. He has shown that *Isatine*, which is oxidised blue indigo, when treated with potash, yields aniline, and that chlorisatine and bromisatine, when treated in the same way, yield products of the type of aniline, in which hydrogen is replaced by chlorine, bromine, or both. Aniline assumes a deep violet colour when brought into contact with chloride of lime. It is remarkable for its power of entering into combination with other substances. Hofmann has obtained it from other substances besides isatine. When anthranilic acid is treated with powdered glass, it is resolved into carbonic acid and aniline. It may, however, be best prepared by the reduction of nitrobenzol by means of acetic acid and iron filings.

Salicylamide and *Nitrotoluole* both yield this substance when exposed to heat with the bases lime, or baryta. The first yields little, but the last compound is entirely resolved into aniline and carbonic acid. The following is a list of substances which are formed by the simple substitution of other elements for atoms of hydrogen in the aniline base:—

Aniline	$C_{12}H_7N$
Chloraniline	$C_{12}H_6ClN$
Dichloraniline	$C_{12}H_5Cl_2N$
Trichloraniline	$C_{12}H_4Cl_3N$
Bromaniline	$C_{12}H_6BrN$
Dibromaniline	$C_{12}H_5Br_2N$
Tribromaniline	$C_{12}H_4Br_3N$
Chlorodibromaniline	$C_{12}H_4ClBr_2N$
Nitraniline	$C_{12}H_6(NO_4)N$
Nitrodibromaniline	$C_{12}H_4Br_2(NO_4)N$
Ethylphenylamine	$C_{12}H_6(C_4H_5)N$
Diethylphenylamine	$C_{12}H_5(C_4H_5)_2N$

Chemically, these compounds are of the highest interest. In the case of bromaniline, and chloraniline, chlorine and bromine are substituted for hydrogen, and this was one of the first instances known of the substitution of other elements for hydrogen in a basic compound, although many instances have since occurred. It will also be observed from these compounds that aniline has a close resemblance to ammonia. This is seen also in the fact, that just as ammonia forms the compounds carbamide and oxamide, so aniline will yield under the same circumstances *carbanilide* and *oxanilide*. It also forms acid anilides, as carbanilic acid, analogous to carbamic acid. Hofmann has also made the discovery that just as cyanate of ammonia passes into urea, and the cyanate of methylamine into *methylo-urea*, so cyanate of aniline passes spontaneously into *anilo-urea*. In fact, the more recent researches of Wurtz and Hofmann have clearly established this close relationship between aniline and ammonia. For a full account of the chemistry of this highly interesting compound the reader should consult the papers of Dr. Hofmann, in the 'Philosophical Transactions,' and the 'Journal of the Chemical Society.' [Organic Bases.]

ANILOCYANIC ACID. *Carbanile, Cyanate of Phenyl* ($C_{14}H_5NO_2$). A liquid organic body obtained by the distillation of oxamelanile.

ANIMAL FOOD, PRESERVATION OF. [Antiseptics.]

ANIMAL MAGNETISM. [Mesmerism.]

ANIMAL STRENGTH. Information on this branch of mechanical philosophy will always be received with interest so long as it shall be found necessary to employ men or animals, either in conveying burdens or in giving motion to machinery, since by it the employer is enabled to ascertain what is the greatest quantity of useful work which may be obtained from such agents without subjecting them to a degree of fatigue which might in time prove injurious to their health or bodily powers.

As early as the year 1680, Borelli published a treatise, entitled 'De Motu Animalium;' and since that time the determination of numerical expressions for the amount of human and animal labour has occupied the attention of many distinguished mathematicians and experimentalists. It has been said that the strengths of different animals of the same species, or of the same animal at different times, are in a *triplicate* proportion of the quantities of their blood; the whole strength of an animal being the force of all the muscles taken together, which are directly nourished by the blood. If, however, the blood be so altered as to increase or diminish the strength, it amounts to the same as if the blood were in a natural state, but its quantity increased or diminished in the same proportion. M. de la Hire remarked that the strength of an ordinary man in walking, is only 27 lbs., but that this would be much greater, if he walked backwards. A horse draws, he says, horizontally, as much as seven men, that is, 189 lbs. But to none is this subject so much indebted as to Coulomb. The dynamical unit employed by Coulomb is one kilogramme (= 2·2055 pounds avoirdupois), which is supposed to be transported to a distance equal to one kilometre (= 0·6214 mile), and his expression for strength is the product of the number of kilogrammes in a burden by the number of kilometres in the distance in which the burden is conveyed during one working day of eight hours. For convenience, however, the unit of weight in this article, is one pound avoirdupois, and the unit of distance is one mile; so that the expression for strength is the product of the number of pounds by the number of miles to which they may be conveyed in one such day.

With respect to men, Coulomb found that when a man travels unloaded on level ground he can walk 31 miles daily. Now, assuming the weight of a man to be 160 lbs., we have 160 × 31 or 4960 for the measure of his strength or the quantity of action, which is, consequently, equivalent to that of a machine capable of carrying 4960 lbs. to a distance of one mile, or one pound to a distance of 4960 miles in one day.

He found also, from a mean of the work done by the porters of Paris, that with a burden equal to 128 lbs. a man can walk 9·72 miles in a day, from which it follows (the weight of a man being 160 lbs.) that the quantity of action is (160 + 128) × 9·72, or 2799. If the weight of the man be not included, the quantity of action is 128 × 9·72, or 1244; and this is to be considered as the useful effect. Subtracting 2799 from 4960, we have 2161 for the measure of the action, lost in consequence of the burden; but the useful effect, which in the first case was nothing, is in the second expressed by 1244.

By means of a formula, which was given by Euler, with the data afforded by these experiments, it is found that 272 lbs. constitute the greatest burden which a man of average strength can support, and under which he cannot move. It is found, moreover, that the useful effect is at a maximum when a man is loaded with 121 lbs.: under this burden he can walk 10½ miles, nearly, in a day; and consequently the greatest useful effect is expressed by 1250.

Coulomb further determined, that when a man ascends a convenient flight of steps unloaded, the vertical heights of all the ascents during one day being added together, were equal to 1·82 mile; the quantity of action may therefore be expressed by 160 × 1·82 or 291, as if the action were equivalent to that of a machine which could raise 291 lbs. to the height of 1 mile vertically, or one pound to the height of 291 miles during a day. When loaded with 150 lbs. the vertical height ascended was 0·494 mile: the whole quantity of action is, therefore, in this case (160 + 150) × 0·494, or 153, while the useful effect is 150 × 0·494, or 74; that is, 74 lbs. raised 1 mile vertically.

It is remarkable that, from the result of Coulomb's experiments on the power of men ascending steps, both the greatest weight which a man can carry without moving, and the weight which he should bear to render his useful effect a maximum, are nearly the same in this case as they were found to be from experiments made with burdens carried on level ground.

Coulomb has also made experiments to determine the quantity of action in the case which most generally occurs when heavy goods are carried in towns, viz. that in which a porter, having delivered his burden, returns unloaded for another; and his conclusion is, that, in order to produce the most useful effect in this case, the greatest burden which a man should carry on level ground is 135 lbs., and with this he should walk seven miles. The quantity of useful action is therefore 135 × 7, or 945.

It is said that a London porter can carry 200 lbs. on his shoulders at the rate of three miles per hour; but this action can only be continued during a short time.

The following statements of the strength of men are taken from Hachette's 'Traité des Machines,' and from other sources; the numerical values being reduced so as to express the number of pounds carried by a man one mile per day of eight hours:—

Drawing a vessel on a canal	753459
Conveying a load (110 lbs.) in a wheelbarrow (1·018 mile per hour)	896
Drawing a small waggon on four wheels over rather unequal ground	857
Pulling horizontally, the weight being raised by a rope passing over a pulley	378
Rowing in a boat	374
Thrusting horizontally, as at a capstan	368
Turning a winch and axle	159
Digging with a spade	85·3
A soldier marching (12·43 miles) with his arms, &c. (60 lbs.) daily	745

With respect to the horse, the most useful way of employing his strength is to make him draw loads in a cart or waggon; but, even for such work, the estimates which have been made of the quantity of action performed daily are various.

According to Tredgold a horse can draw 125 lbs. at the rate of 2½ miles per hour, which, for one day, would give 125 × 2½ × 8, or 2500. But Messrs. Boulton and Watt ascertained from trials, purposely made, that a strong horse can draw 125 lbs. at the rate of 3 miles per hour; and the measure of the power of such a horse is 3000, which expresses a number of pounds drawn one mile in a day. If this be multiplied by the number of feet in a mile, and the product be divided by the number of minutes in eight hours, the result (= 33000) denotes a weight in pounds drawn one foot per minute during the eight hours; and that result is now universally adopted as a measure of the power of a horse.

The useful effect of a horse when walking in a circle, as in some mills, is considered as equivalent to .	800
A horse carrying a soldier with arms, &c. (= 200 lbs.), can go 25 miles in a day, which gives	5000
An African dromedary carrying only his rider (160 lbs.) can go between seven and eight miles per hour during nine or ten hours, which gives 160 × 7½ × 9½, or	11400
An Asiatic camel will carry burdens weighing from 500 to 800 lbs. (suppose 600) at the rate of two and a half miles per hour. This, for a day of eight hours, gives 600 × 2½ × 8, or	12000

The velocity of a horse in walking is estimated at 5½ feet per second, or 3¾ miles per hour; in trotting 12 feet per second, or 8⅓ miles per hour; and in galloping 18 feet per second, or 12¼ miles per hour.

The following remarks are taken from Major Griffiths's 'Artillerists' Manual':—The average weight of artillery horses is 10 cwt. 2 qrs. The most useful mode of applying a horse's power is in draught, and the worst is in carrying a load. This is owing to the structure of the animal. It has been found that three men carrying each 100 lbs. will ascend a hill with greater rapidity than one horse carrying 300 lbs. When a horse has a large draught in a waggon, however, it is found useful to load his back to a certain extent; this prevents him from inclining so much forward, as he would otherwise do, and consequently frees him from the fatigue of great muscular action. The best disposition of the traces in draught is when they are perpendicular to the collar; when the horse stands at ease, the traces are then inclined to the horizon, at an angle of about 15°; but when he leans forward to draw, the traces should then become nearly parallel to the road. The most proper inclination, however, is determined from the relation which subsists between the friction and the pressure in every particular case. When a horse is employed in moving a machine, by travelling in a circular path, the diameter ought not to be less than 25 or 30 feet, and in most cases 40 feet should be preferred; at all events, it must not be less than 18 feet.

The following table shows the *maximum quantity of labour* which a horse of average strength is capable of performing at different velocities, on canals, railways, and roads, but in comparing this table with practice at the higher velocities, it is found necessary to add one-third more than the *useful effect* for the total mass moved. Whatever the difficulties of a road may be, ten horses are as many as can be harnessed with effect to one carriage.

Velocities per hour.	Day's work.	Force of Traction.	Useful effect per day for 1 Mile in distance on a Canal.	Railway.	Level Road.
Miles.	Hours.	lbs.	Tons.	Tons.	Tons.
2½	11·5	83⅓	520	115	14
3	8		243	92	12
3½	5·9		153	82	10
4	4·5		102	72	9
5	2·9		52	57	7·2
6	2		30	48	6
7	1·5		19	41	5·1
8	1·8		12·8	36	4·5
9	·9		9	32	4
10	·75		6·6	28·8	3·6

The following is the result of experiments with a light four-wheeled cart, weighing, with its load, 1000 lbs., drawn on different sorts of roads (12½ lbs. being deducted from the force of traction, for the friction at the axles, which were of wood):—

	Force of traction.
Turnpike road, hard and dry	18
" " dirty	26½
" " new gravelled	130⅓
Loose sandy road	191½

NOTE.—An ox can draw about 4 cwt., and a pair of oxen 9 cwt. on a level road.

ANIMAL SUBSTANCES. Among the important and indispensable materials of manufactures, are those which are derived from the animal kingdom. Few persons are aware, unless actually engaged in manufacturing operations, how numerous and varied these materials are. The bounty of nature has placed at the disposal of man so large a number of substances, derived from so large a number of animals, that there is scarcely an article in daily use but can exhibit an application of some such substance, either in its formation or its decoration. The exterior and the interior, the solids and the liquids—all parts of some animals, and numerous parts of many, admit of being thus industriously applied.

In the classified list of objects drawn up for the Commissioners of the Great Exhibition of 1851, the principal materials of manufactures and the arts derived from the animal kingdom were enumerated, and an attempt was made to arrange them into some convenient systematic form. In the first place, the whole series was divided into three sections, namely; 1st, Animal substances used as food; 2nd, Animal substances used for medicinal purposes; and 3rd, Animal substances used in manufactures.

Almost every part of almost every species of animal serves as food to some variety or other of the human race. The flesh, the eggs of birds, and the milk of mammalia, are obviously the chief forms in which animal food is presented; but there are many other forms to which more or less of preparative process has been applied; such as preserved meats for long voyages; portable soups; concentrated nutriments; consolidated milk; dried gelatine, albumen, and isinglass; caviare and trepang; sharks' fins; nests of the Java swallow; honey, &c.

The animal substances used in the medicinal art are exceedingly numerous. Among them are cod-liver and other animal oils; unguents of spermaceti, lard, oil, and various combinations of the three; musk, castoreum, civet, and ambergris; phosphorus and ammonia, from bones and hartshorn; crabs' eyes (the calcareous concretions formed in the craw-fish), and cuttle-bone; cantharides, and their essence cantharadine; iodine, obtained from marine zoophytes and sponge, &c.

But the animal substances used in manufacturing processes, though perhaps not equalling in quantity those consumed as food, are far more varied in quality and texture. They are so numerous that the Commissioners found it convenient to separate this section into five divisions, namely; Animal substances employed, 1st, for textile fabrics and clothing; 2nd, for domestic or ornamental purposes; 3rd, for serving as agents in the manufacture of other articles; 4th, for the production of chemical substances; and 5th, for pigments and dyes. Under the first division come wool, hair, hair bands and ropes; bristles and whalebone; silk from the silkworm, the pinna, and other insects; feathers, down, and fur; skins, hides, and leather; elytra or beetle wings, for ornaments of dress, &c. Under the second division are included bone, horn, hoofs, ivory, tortoise-shell, shagreen, parchment, vellum, quills, pearls, seed pearls, mother o' pearl, buffalo shells, Bombay shells, black shells, white-edge shells, yellow-edge shells, flat shells, green-snail shells, coral; together with a large number of softer substances, such as sponge, catgut, gold-beaters' skin, bladders, spermaceti, wax, lard, tallows, oils, &c. Under the third division come glue, isinglass, gelatine, bone-black, ivory black, animal charcoal, &c. Under the fourth division are included bones and other substances from which phosphorus, ammonia, cyanides, &c. are procured. Under the fifth division are enumerated cochineal and carmine; dyes from the galls of aphides; gall-stone pigment from ox-gall; lac, in its various forms of stick-lac, seed-lac, lump-lac, shell-lac, lac-lake, and lac-dye; sepia, from the cuttle fish; essence d'orient, obtained from the scales of the bleak, and used in the manufacture of artificial pearls, &c.

Notices of the more important of the above-named substances will be found under their proper headings.

ANIMÉ. A gum resin, of which two kinds are known; the American, which is said to be obtained from incisions in the *Hymenæa Courbaril*, and the Oriental. The American animé is pale yellow to dusky brown, has an agreeable odour, and a specific gravity of 1·03. It contains 2·4 per cent. of a volatile oil. The oriental variety has a yellow or reddish yellow colour, and a specific gravity of 1·0272. Both varieties are employed for scenting pastilles.

ANISAMIC ACID ($C_{16}H_9NO_6$). A colourless crystalline acid, obtained by adding sulphide of ammonium to nitranisic acid.

ANISAMIDE [$NH_2(C_{16}H_7O_4)$]. A crystalline substance, obtained by the action of chloride of anisyl upon ammonia. [AMIDES.]

ANISANILIDE [$NH(C_{16}H_7O_4)(C_{12}H_5)$]—*Phenylanisamide.* A crystalline body, formed by acting upon aniline with chloride of anisyl. [ANISIC ACID.]

ANISHYDRAMIDE (*Hydride of Azoanisyl*) ($C_{48}H_{24}N_2O_6$). A crystalline product of the action of ammonia on hydride of anisyl.

$$\underbrace{3C_{16}H_8O_4}_{\text{Hydride of Anisyl.}} + \underbrace{2NH_3}_{\text{Ammonia.}} = \underbrace{C_{48}H_{24}N_2O_6}_{\text{Anishydramide.}} + 6HO$$

Anishydramide crystallises in brilliant prisms, fusible, and soluble in hot alcohol and ether.

ANISIC ACID—*Draconic Acid* ($C_{16}H_8O_6$). Obtained by M. Cahours by boiling oil of anise with nitric acid of specific gravity 1·2. A yellow resinous mass (nitraniside) first separates, and then crystals of anisic acid are deposited as the liquid cools. Anisic acid is almost tasteless, scarcely soluble in cold, but easily soluble in hot water, in alcohol, and in ether. It fuses at 347°, and may be sublimed unaltered. Distilled with pentachloride of phosphorus, it yields *chloride of anisyl* ($C_{16}H_7O_4Cl$). It also unites with oxide of ethyl, forming *anisic ether* ($C_{16}H_7(C_4H_5)O_6$).

ANISIC ETHER. [ANISIC ACID.]

ANISIDINE—*Methyl-phenidine* ($C_{14}H_9NO_2$). An oily solid, formed by the action of sulphide of ammonium upon nitrophenate of methyl.

ANISINE ($C_{48}H_{24}N_2O_6$). An organic base, formed by the isomeric transformation which hydride of azoanisyl suffers when maintained at a temperature of 330° F. for several hours. It crystallises in colourless prisms possessing a strong alkaline reaction; is soluble in alcohol, and slightly so in boiling water. It forms crystallisable salts with acids.

ANISÖIN. A substance obtained by acting on the oil of anise by sulphuric acid or the chlorides of tin and antimony. It is analogous to benzoin.

ANISOL—*Phenate of Methyl* $\left(\begin{matrix}C_{12}H_5\\C_2H_3\end{matrix}\right\}O_2\Big)$. Prepared by distilling anisic acid with an excess of caustic baryta. It is a colourless, very mobile liquid of an aromatic odour. It boils at 306° F.

ANISYL ($C_{16}H_7O_4$). The hypothetical radical of anisic acid. It may be regarded as methyl-salicyl, thus:—

Salicyl	$C_{14}H_5O_4$
Anisyl	$C_{14}H_4(C_2H_3)O_4$.

ANKER, a measure of wine and spirits, particularly of the latter, formerly in use, containing 10 old wine gallons, or 8⅓ imperial gallons, that is, 2310·62 cubic inches. This measure is also in use in various parts of Europe, and varies according to the following table:—

Place.	Anker in old wine gallons.	Anker in imperial gallons.
Amsterdam	10·250	8·542
Berlin	9·894	8·245
Copenhagen	9·950	8·292
Danzig	9·900	8·250
Hamburg	9·563	7·969
Oldenburg	10·988	9·157
Pernau	10·233	8·528
Revel	11·172	9·310
Riga	10·333	8·611
Russia	9·738	8·115
Rotterdam	9·998	8·332
Rostock	9·562	7·968
Stettin	13·700	11·417
Sweden	10·372	8·643

ANNALS, in Latin *Annales*, is derived from 'annus,' a year. Cicero, in his second book, On an Orator ('De Oratore,' chap. xiii.), informs us that from the commencement of the Roman state down to the time of Publius Mucius, it was the custom for the Pontifex Maximus, or high priest, annually to commit to writing the transactions of the past year, and to exhibit the account publicly on a tablet (*in albo*) at his house, where it might be read by the people. Mucius was Pontifex Maximus in the beginning of the 7th century from the foundation of Rome. These are the registers, Cicero adds, which we now call the 'Annales Maximi,' the great annals. It is probable that these annals are the same which are frequently referred to by Livy under the title of the 'Commentarii Pontificum,' and by Dionysius under that of the *ἱέραι δέλτοι*, or 'Sacred Tablets.' Cicero, both in the passage just quoted, and in another in his first book On Laws ('De Legibus,') speaks of them as being extremely brief and meagre documents. It may, however, be inferred from what he says, that parts of them at least were still in existence in his time, and some might be of considerable antiquity. Livy only says that *most* of the contents of the Pontiffs' Commentaries were lost at the burning of the city after its capture by the Gauls. It is evident, however, that they were not in Livy's time to be found in a perfect state even from the date of that event (A.U. 363); for he is often in doubt as to the succession of magistrates in subsequent periods, which it is scarcely to be supposed he could have been, if a complete series of these annals had been preserved.

The word annals, however, was also used by the Romans in a general sense; and it has been much disputed among the critics what was the true distinction between annals and history. Cicero, in the passage in his work 'De Oratore,' says, that the first narrators of public events, both among the Greeks and Romans, followed the same mode of writing with that in the 'Annales Maximi;' which he further describes as consisting in a mere statement of facts briefly and without ornament. In his work 'De Legibus' he characterises history as something quite distinct from this, and of which there was as yet no example in the Latin language. It belongs, he says, to the highest class of oratorical composition.

This question has been considerably perplexed by the division which is commonly made of the historical works of Tacitus, into books of annals, and books called histories. As what are called his 'Annals' are occupied with events which happened before he was born, while in his 'History' he relates those of his own time, some critics have laid it down as the distinction between history and annals, that the former is a narration of what the writer has himself seen, or at least been contemporary with, and the latter of transactions which had preceded his own day. Aulus Gellius ('Noctes Atticæ,' v. 18) has stated this doctrine, which, after his manner, he has endeavoured to support by a reference to the etymology of the word history, from the Greek *ἱστορέω*, properly to inquire in person.

It must be evident that this is quite an unfounded notion. Without attempting to define at present what history properly is, which will be more conveniently done under the word itself, we may venture to assume, that it does not mean merely memoirs of events by contemporaries. And it is equally clear that there is nothing in the term annals which should make it exclusively applicable to accounts of past ages. We doubt if Tacitus himself ever gave the name of histories to any of his writings. If he gave either work a title at all, more probably he gave to both that of annals only. We rather think it will be found, that wherever he mentions his historical writings, he refers to them by this name. It is, at any rate, by no means certain that the common division either originated with him, or was even recognised by others of his own age.

Tacitus has himself in one passage intimated distinctly what he himself understood annals to be, as distinguished from history. In his 'Annals' (commonly so called), lib. iv. cap. 71, he states his reason for not giving the continuation and conclusion of a particular narrative which he had commenced, to be simply the necessity under which he had laid himself by the form of composition he had adopted of relating events strictly in the order of time, and always finishing those of one year before entering upon those of another. The substance of his remark is, that "the nature of his work required him to give each particular under the year in which it actually happened." This, then, was what Tacitus conceived to be the task which he had undertaken as a writer of annals, "to keep everything to its year." Had he been writing a history (and in the instance quoted above, he insinuates he had the inclination, if not the ability, for once to act the historian), he would have considered himself at liberty to pursue the narrative he was engaged with to its close, not stopping until he had related the winding up of the whole. But remembering that he professed to be no more than an annalist, he restrains himself, and feels it to be his business to keep to the events of the year.

It is of no consequence that on some other occasions Tacitus may have deviated somewhat from the strict line which he thus lays down for himself—that he may have for a moment dropped the annalist and assumed the historian. If it should even be contended that his narrative does not in general exhibit a more slavish submission to the mere succession of years than others that have been dignified with the name of historians, that is still of no consequence. He may have satisfied himself with the more humble name of an annalist, when he had a right to the prouder one of an historian; or the other works referred to may be wrongly designated histories. It may be, for instance, that he himself is as much an historian in what are called his 'Annals' as he is in what is called his 'History.' In that case all we can say is, upon any interpretation of the words that may be advanced (except indeed the foolish one proposed by Aulus Gellius), that one of the titles is wrong.

In lib. iii. cap. 65 of his 'Annals,' Tacitus tells us that it formed no part of the plan of his 'Annals' to give at full length the sentiments and opinions of individuals, except they were signally characterised either by some honourable or disgraceful traits. In chap. 22 of the treatise on Oratory, attributed to Tacitus, the author expresses his opinion of the general character of the style of ancient annals; and ('Annal.' xiii. 31) he carefully marks the distinction between events fit to be incorporated into annals and those which were only adapted to the Acta Diurna. [ACTA DIURNA.]

The distinction we have stated between history-writing and annal-writing seems to be the one that has been commonly adopted. An account of events digested into so many successive years is usually entitled, not a history, but annals. The 'Ecclesiastical Annals' of Baronius, and the 'Annals of Scotland,' by Sir David Dalrymple (Lord Hailes), are well-known examples. In such works so completely is the succession of years considered to be the governing principle of the narrative, that that succession is sometimes preserved unbroken even when the events themselves would not have required that it should, the year being formally enumerated although there is nothing to be told under it. The year is at least always stated with equal formality whether there be many events or hardly any to be related as having happened in it. In this respect annals differ from a catalogue of events with their dates, as, for instance, the 'Parian Chronicle.' The object of the latter is to intimate in what year certain events happened; of the former, what events happened in each year. The history of the Peloponnesian war by Thucydides has the character of annals. The events are arranged distinctly under each year, which is further divided into summers and winters. All political reflections are, for the most part, placed in the mouths of the various commanders on each side.

In the 'Rheinisches Museum für Philologie,' &c., ii. jahrg. 2 heft. pp. 293, &c., there is a disquisition by Niebuhr on the distinction between History and Annals, in which he limits the latter nearly as has been done above. But the greater part of the paper is taken up in endeavouring to account for the definition given by Aulus Gellius, which is illustrated in a manner perhaps more fanciful and ingenious than convincing. There is a translation of it in the Sixth Number (for May, 1833) of the 'Cambridge Philological Museum.'

It scarcely need be noticed that the term annals is popularly used in a very loose sense for a record of events in whatever form it may be written—as when Gray speaks of

"The short and simple annals of the poor."

In the Romish Church a mass said for any person every day during a whole year was anciently called an annal; and sometimes the same word was applied to a mass said on a particular day of every year.

(Du Cange, *Glossarium ad Scriptores Mediæ et Infimæ Latinitatis.*)

ANNA'TES, from *annus*, a year, a sum paid by the person presented to a Church living, being the estimated value of the living for a year. It is what is otherwise called *Primitiæ*, or First Fruits. [FIRST FRUITS.] The amount in each cure was formerly regulated, in England, by a valuation of benefices, made by Walter, bishop of Norwich, under the direction of Pope Innocent IV., in 1254, in the reign of Henry III. A new valuation was made in 1292, in the reign of Edward I.; and a third in 1535, in the reign of Henry VIII., according to which (commonly called the Liber Regis, or King's Book) the clergy are at present rated. These fines, before the Reformation, went to the bishop or to the pope: on the supremacy being transferred to the crown, they went along with it. In the reign of Queen Anne they were given up to form a fund for the augmentation of poor livings; hence called Queen Anne's Bounty. The administration of this fund is now regulated by 1 & 2 Vict. c. 20. In Ireland, until the 3 & 4 Will. IV. c. 47 (An Act to alter and amend the Laws relating to the Temporalities of the Church in Ireland), the first fruits were applied in the first instance to the repair of churches, and to the augmentation of poor livings after that object had been satisfied. By that statute the demand of first fruits is abolished (§ 13), and in lieu of it, all ecclesiastical incomes above a certain amount are to pay yearly a tax regulated by their value. In Scotland, by the Act of Parliament, 1672, c. 13, the executors of every holder of a spiritual benefice are allowed the first half-year's stipend after that to which the incumbent was entitled at the time of his death; and this is called the Ann, or Annat. As it belongs to the executors of the clergyman, and not to himself, it can neither be assigned by him during his life, nor seized in payment of his debts. (Ersk. 'Inst.,' ii. 10, 66.)

ANNEALING. There are certain substances, more especially glass and some of the metals, which on sudden cooling after having been melted, acquire great brittleness, and in the case of glass, a disposition to fly to pieces by moderate changes of temperature, or slight external force. This is remedied by annealing, which, with respect to glass, consists in heating it, below the point at which it softens, in what are termed *annealing ovens*, the glass being gradually removed from the hotter to the cooler parts of the furnace. The brittleness of glass has been attributed to the disturbance, attendant upon the hasty cooling, in the regular arrangement of its particles. [GLASS.]

The metals also suffer remarkable changes as to their hardness, toughness and brittleness; this is especially the case with iron after it has been converted into steel. The alteration of structure which they undergo is not thoroughly understood; it is, however, certain that some malleable metals which crystallise on cooling, are brittle in their crystalline state, and that this structure is altered, and they are rendered tough by heating and rolling. This is remarkably the case with zinc, which is incapable of extension under the hammer, except in a slight degree, without cracking; but when it has been passed through the rollers, at a moderate increase of temperature, it becomes almost as flexible and as tough as copper. This change must be derived from some alteration of structure, and fresh arrangement of the particles, which must be considered as owing to a process, if not identical with annealing, yet bearing a strong analogy to it. [BRASS; STEEL.]

ANNIHILATOR, FIRE. In addition to the machines noticed under FIRE ENGINE and FIRE ESCAPE, another protection from fire has been introduced by Mr. Phillips, under the name of the *Fire Annihilator.* Mr. Phillips took out his patent in 1849. The materials employed consist of sugar and chlorate of potash, mixed and boiled together into a homogeneous mass. This is placed in a perforated cylinder, within a second perforated cylinder, contained in a third but air-tight cylinder; and the whole put into an outer case. Water is placed in the space between the bottoms of the third cylinder and outer casing; a vertical pipe opens from this space to the space between the second and third cylinders. By the action of the heated water, aided by a mechanical contrivance, a particular gas or vapour is generated from the chlorate, and is allowed to escape through an opening at the top of the case. It is this gas which is intended to act so remarkably upon a burning mass as to extinguish flame.

With this apparatus Mr. Phillips has made many experiments which have attracted a good deal of public attention. A display was made at Vauxhall Gas Works, in October, 1849; model houses and shops, filled with combustibles, were set on fire, with a view of showing how rapidly the annihilator could extinguish the flames. The machine is placed where it can be influenced by the heat of the conflagration; and the resulting gas has a remarkable effect in extinguishing flame; but it does *not* extinguish red heat unaccompanied by flame. Experiments were made in the early part of 1850 at Trentham Park, at the Paddington Railway Station, and at the West India Docks; but the annihilator on these occasions scarcely merited the good opinion of its admirers. Shortly after this, the Board of Ordnance permitted a brick building to be constructed in Woolwich Marsh, and made to represent as nearly as practicable (without incurring too much expense) a three storied house, which was then filled with cheap furniture; and a similar experiment was conducted here.

The truth seems to be (so far as has yet been shown), that in close rooms, or confined spaces generally, the liberated gases of the annihilator may be serviceably used to extinguish flame; but that where there is plenty of access for external air, the action of the machine becomes impaired. So far as the mere setting to work is concerned, it is easy and simple; but an experience of ten years (1849 to 1859) has not tended far towards the establishment of the fire-annihilator in practical use.

ANNIVE'RSARY, the yearly return of any remarkable day, called, in old English, by the expressive term year-day.

Anniversary days are festivals celebrated by the Romish church in honour of the saints, one or two of whom are assigned to every day in the year. In the Church of England the only anniversaries are the solemn ones of the birth and death of our Saviour, but there are special services for some of the saints. There are also some few fairs held on saints' days, but without any present recognition of the saints, and with scarcely a remembrance of them. The birth-day of the reigning monarch is very generally celebrated by holidays and rejoicings; the anniversary of the Gunpowder Plot has been rescued from oblivion by the love of school-boys for fire-works and the pageant of Guy Fawkes; the oaken bough still preserves the remembrance of the restoration of the Stuarts; and Valentine yet makes a considerable contribution to the post-office revenue.

Literary and scientific associations generally celebrate the anniversary of their original institution, and social parties are held in domestic life on the birth-days of heads of families.

ANNUITY, a term derived from the Latin *annus*, a year; signifying, in its most general sense, any fixed sum of money which is payable either yearly or in given portions at stated periods of the year. Thus, the lease of a house, which lets for 50*l.* a year, and which has 17 years to run, is to the owner an annuity of 50*l.* for 17 years. In an ordinary use of the term, it signifies a sum of money payable to an individual yearly, during life. In the former case, it is called, in technical language, an *annuity certain*, and in the latter, a *life annuity*.

It is evident that every beneficial interest which is either to continue for ever, or to stop at the end of a given time, such as a freehold, a lease, a debt to be paid in yearly instalments, &c., is contained under the general head of an *annuity certain;* while every such interest which terminates with the lives of any one or more individuals, all that in law is called a *life estate*, and all salaries, as well as what are most commonly known by the name of life annuities, fall under the latter term. Closely connected with this part of the subject are COPYHOLDS (which see), in which an estate is held during certain lives, but in which there is a power of renewing any life when it drops, that is, substituting another life in place of the former, on payment of a fine—REVERSIONS, or the interest which the next proprietor has in any estate, &c., after the death of the present—and *life-insurance* [INSURANCE], in which the question is, what annuity must A. pay to B. during his life, in order that B. may pay a given sum to A.'s executors at his death.

If money could not be improved at interest, the value of an annuity certain would simply be the yearly sum multiplied by the number of years it is to continue to be paid. Thus a lease for three years of a house which is worth 100*l.* a year, might either be bought by paying the rent yearly, or by paying 300*l.* at once. A life annuity, in such a case, will be worth an annuity certain, continued for the average number of years lived by individuals of the same age as the one to whom the annuity is granted. But if compound interest be supposed, which is always the case in real transactions of this kind, the landlord, in the case of the annuity certain just alluded to, must only receive such a sum as, when put out to interest, with 100*l.* subtracted every year for rent, will just be exhausted at the end of three years. To exemplify this, let us suppose that money can be improved at 4 per cent. In Table I., in the column headed 4 p. c. (4 per cent.) we find 2·775 opposite to 3 in the first column, by which is meant that the present value of an annuity of *one pound* to last three years is 2·775*l.*, or $2\frac{775}{1000}$*l.* The present value of an annuity of 100*l.* under the same circumstances is, therefore, 277·5*l.*, or 277*l.* 10*s.* This is the value of a lease for three years corresponding to a yearly rent of 100*l.* The landlord who receives this, and puts it out at 4 per cent., will, at the end of one year, have 288*l.* 12*s.* From this he subtracts 100*l.* for the rent which has become due, and puts out the remainder 188*l.* 12*s.* again at 4 per cent. At the end of a year this has increased to 196*l.* 2*s.* 10¾*d.*, from which 100*l.* is again subtracted for rent. The remainder, 96*l.* 2*s.* 10¾*d.*, again put out at interest, becomes at the end of the year 99*l.* 19*s.* 9*d.*, within three pence of the last year's rent. This little difference arises from the imperfection of the Table, which extends to three decimal places only.

TABLE I.—PRESENT VALUE OF AN ANNUITY OF ONE POUND.

No. of Years.	3 p. c.	3½ p. c.	4 p. c.	5 p. c.
1	·971	·966	·962	·952
2	1·913	1·900	1·886	1·859
3	2·829	2·802	2·775	2·723
4	3·717	3·673	3·630	3·546
5	4·580	4·515	4·452	4·329
6	5·417	5·329	5·242	5·076
7	6·230	6·115	6·002	5·786
8	7·020	6·874	6·733	6·463
9	7·786	7·608	7·435	7·108
10	8·530	8·317	8·111	7·722
15	11·938	11·517	11·118	10·380
20	14·877	14·212	13·590	12·462
25	17·413	16.482	15·622	14·094
30	19·600	18·392	17·292	15·372
40	23·115	21·355	19·793	17·159
50	25·730	23·456	21·482	18·256
60	27·676	24·945	22·623	18·929
70	29·123	26·000	23·395	19·343
For ever	33·333	28·571	25·000	20·000

To find the present value of an annuity of 1*l.* per annum continued for 10 years, interest being at 5 per cent., look in the column headed 5 p. c., and there, opposite to 10 in the first column, will be found the value of 7·722*l.*, or 7*l.* 14*s.* 6½*d.* This would be commonly said to be 7·722 *years' purchase* of the annuity. Decimals of a pound may be reduced to shillings and pence, and the converse, by the following Table:—

TABLES II. AND III.—FOR REDUCING DECIMALS OF A POUND TO SHILLINGS AND PENCE, AND THE CONVERSE.

Dec.	s.	Dec.	s.	d.	Dec.	d.
·1	2	·01	0	2½	·001	0¼
·2	4	·02	0	5	·002	0½
·3	6	·03	0	7¼	·003	0¾
·4	8	·04	0	9½	·004	1
·5	10	·05	1	0	·005	1¼
·6	12	·06	1	2½	·006	1½
·7	14	·07	1	5	·007	1¾
·8	16	·08	1	7¼	·008	2
·9	18	·09	1	9½	·009	2¼

s.	Dec.	d.	Dec.	f.	Dec.
1	·05	1	·004	¼	·001
2	·1	2	·008	½	·002
3	·15	3	·013	¾	·003
4	·2	4	·017		
5	·25	5	·021		
6	·3	6	·025		
7	·35	7	·029		
8	·4	8	·033		
9	·45	9	·037		
10	·5	10	·042		
		11	·046		

For example, what is ·665*l.* in shillings and pence?

TABLE II.	·6	is	£0	12	0
	·06	„		1	2½
	·005	„			1¼
	·665		£0	13	3¾

Again, what is 17*s.* 10¾*d.* in decimals of a pound?

TABLE III.	£0	10	0	is	·5
		7	0	„	·35
			10	„	·042
			¾	„	·003
	£0	17	10¾		·895

These conversions are not made with perfect exactness, as only three decimal places are taken. The error will never be more than one farthing.

To use Table I. where the number of years is not in the table, but is intermediate between two of those in the table, such a mean must be taken between the annuities belonging to the nearest years above and below the given year, as the given year is between those two years. This will give the result with sufficient nearness. We must observe, that no tables which we have room to give are sufficient for more than a first guess, so to speak, at the value required, such as may enable any one who is master of common arithmetic, not to form a decisive opinion on the case before him, but to judge whether it is worth his while to make a more exact enquiry, either by taking professional advice, or consulting larger tables. As an example of the case mentioned, suppose we ask for the value of an annuity of 1*l.* continued for 12 years, interest being at 4 per cent. We find in Table I., column 4 per cent.—

For	10	years	8·111
„	15	„	11·118
	Difference		3·007

Since 5 years adds 3·007 to the value of the annuity, every year will add about one-fifth part of this, or ·601, and two years will add about 1·202. This, added to 8·111, gives 9·313. The real value is more near to 9·385, and the error of our table is ·07 out of 9·313, or about the 133rd part of the whole. The higher we go in the table, the less proportion of the whole will this error be.

The last line in Table I. gives the value of the annuity of 1*l.* continued for ever: for example, at 5 per cent., the value of 1*l.* for ever, or, as it is called, a *perpetuity* of 1*l.*, is 20*l.* This is the sum which at 5 per cent. yields 1*l.* a year in interest only, without diminution of the principal. We see that an annuity for a long term of years differs very little in present value from the same continued for ever: for example, 1*l.* continued for 70 years at 4 per cent. is worth 23·395*l.*, while the perpetuity at the same rate is worth only 25*l.* Hence the present value of an annuity which is not to begin to be paid till 70 years have elapsed, but is afterwards to be continued for ever, is 1·605 at 4 per cent.: which sum improved during the 70 years, would yield the 25*l.* necessary to pay the annuity for all years succeeding.

TABLE IV.—AMOUNT OF AN ANNUITY OF ONE POUND.

Y.	3 p. c.	3½ p. c.	4 p. c.	5 p. c.
1	1·000	1·000	1·000	1·000
2	2·030	2·035	2·040	2·050
3	3·091	3·106	3·122	3·153
4	4·184	4·215	4·246	4·310
5	5·309	5·362	5·416	5·526
6	6·468	6·550	6·633	6·802
7	7·662	7·779	7·898	8·142
8	8·892	9·052	9·214	9·549
9	10·159	10·368	10·583	11·027
10	11·464	11·731	12·006	12·578
15	18·599	19·296	20·024	21·579
20	26·870	28·280	29·778	33·066
25	36·459	38·950	41·646	47·727
30	47·575	51·623	56·085	66·439
40	75·401	84·550	95·026	120·800
50	112·797	130·998	152·667	209·348
60	163·053	196·517	237·991	353·584
70	230·594	288·938	364·290	588·529

In this Table we see what would be possessed by the receiver of an annuity at the end of his term, if he put each year's annuity out at interest as soon as he received it. For example, an annuity of 1*l.*, in 40 years, at 5 per cent., amounts to 120·8*l.*, which includes 40*l.* received altogether at the end of the different years, and 80·8*l.*, the compound interest arising from the first year's annuity, which has been 39 years at interest, the second year's annuity, which has been 38 years at interest, and so on, down to the last year's annuity, which has only just been received. When the annuity is payable half-yearly, or quarterly, its present value is somewhat greater than that given in the preceding Table. For the annuitant, receiving certain portions of his annuity sooner than in the case of yearly payments, gains an additional portion of interest. Since 4 per cent. is 2 per cent. half-yearly and 1 per cent. quarterly, and since every term contains twice as many half-years as years, and four times as many quarters, it is evident that an annuity of 100*l.* a-year, payable half-yearly, at 4 per cent., for 10 years, is the same in present value as one of 50*l.* per annum, payable *yearly*, at 2 per cent., for 20 years. Again, 100*l.* a-year, payable quarterly for 10 years, money being at 4 per cent., is equivalent to an annuity of 25*l.*, payable yearly for 40 years, money being at 1 per cent.

The principles on which the calculation of life annuities depends will be more fully explained in the articles PROBABILITY and MORTALITY. Let us suppose 100 persons, all of the same age, buy a life annuity at the same office. Let us also suppose it has been found out, that of 100 persons at that age, 10 die in the first year on the average, 10 more in the second year, and so on. If, then, it can be relied upon that 100 persons will die nearly in the same manner as the average of mankind, or at least, that in such a number the longevity of some will be compensated by the unexpected death of others, the fair estimation of the value of a life annuity to be granted to each may be made as follows. To make the question more distinct, let us suppose the bargain to be made on the 1st of January, 1859, so that payment of the annuities is due to the survivors on new-year's day of each year. Moreover, let each year's annuity be made the subject of a separate contract. The first question is, what ought each individual to pay in order that he may receive the annuity of 1*l.*, if he survives, in 1860? By the general law of mortality, we suppose that only 90 will remain to claim, who will, therefore, receive 90*l.*, among them, the remaining 10 having died in the interval. It is sufficient, therefore, to meet the claims of 1860, that the whole 100 pay among them, January 1, 1859, such a sum as will, when put out at interest, (suppose 4 per cent.,) amount to 90*l.* on January 1, 1860. This sum is 86·654*l.*, and its hundredth part is ·86654*l.*, which is, therefore, what each should pay to entitle himself to receive the annuity in 1860. There will be only 80 to claim in 1861, and, therefore, the whole 100 must among them pay as much as will, put out at 4 per cent. for 2 years, amount to 80*l.* This sum is 73·968*l.*, and its hundredth part is ·73968*l.*, which is, therefore, what each must pay, in order to receive the annuity, if he lives, in 1861. The remaining years are treated in the same way, and the sum of the shares of each individual for the different years is the present value of an annuity for his life. We must observe, that in the term *value of an annuity*, it is always implied that the first annuity becomes payable at the expiration of a year after the payment of the purchase money.

The value of a life annuity depends, therefore, upon the manner in which it is presumed a large number of persons similarly situated with the buyer, would die off successively. Various tables of these *decrements of life*, as they are called, have been constructed, from observations made among different classes of lives. Some make the mortality greater than others; and of course, Tables, which give a large mortality, give the value of the annuity smaller than those which suppose men to live longer. Those who buy annuities would, therefore, be glad to be rated according to tables of high mortality or low expectation of life; while those who sell them would prefer receiving the price indicated by tables which give a lower rate of mortality. In insurances the reverse is the case: the shorter the time which a man is supposed to live, the more must he pay the office, that the latter may at his death have accumulated wherewithal to pay his executors. We now give in Table V., the values of annuities according to three of the most celebrated Tables.

TABLE V.—PRESENT VALUE OR PURCHASE-MONEY OF A LIFE ANNUITY.

	Northampton.			Carlisle.			Gov. M.	Gov. F.

95	·2	·2	·2	2·8	2·7	2·6	·6	1·0

The first of these is calculated from the Northampton Table, formed by Dr. Price, from observations of burials, &c., at Northampton. As compared with all other Tables of authority, it gives too high a mortality at all the younger and middle ages of life, and consequently, too low a value of the annuity; the second is from the Carlisle Table, formed by Mr. Milne, from observations made at Carlisle. It gives much less mortality than most other Tables, and, therefore, gives higher values of the annuities; but it has since been proved to represent the actual state of life among the middle classes in the century then ending, with much greater accuracy than could have been supposed, considering the local character of the observations from which it was derived. The third table is that constructed by Mr. Finlaison, from the observation of the mortality in the government tontines and among the holders of annuities granted by government in redemption of the national debt, and differs from the former two in distinguishing the lives of males from those of females. Most observations hitherto published unite in confirming the fact, that females, on the average, live longer than males, and in the annuities now granted by government, a distinction is made accordingly. The mean between the values of annuities on male and female lives, according to the Government Tables, agrees pretty nearly with the Carlisle Tables, the rate of interest being the same.

For the materials of Table V., we are indebted to the works of Dr. Price, on 'Reversionary Payments;' of Mr. Milne, on 'Annuities and Insurances;' and to Mr. Finlaison's 'Report to the House of Commons on Life Annuities;' to all of which we refer the reader. The tables are of course very much abridged.

To use the Table V., suppose the value of an annuity of 100*l.* a-year, on a life aged 35, is required, interest being at 4 per cent., which is nearly the actual value of money. We find in the column marked 4 per cent., opposite to 35, under the Northampton Tables 14·0, under the Carlisle 16·0, and under the Government Tables 15·7 or 16·9, according as the life is male or female. These are the number of pounds which ought to buy an annuity of 1*l.*, according to these several authorities; and taking each of them 100 times, we have:—

Northampton Table	1400*l.*
Carlisle Table	1600*l.*
Government Table (males) . . .	1570*l.*
Government Table (females) . . .	1690*l.*

We cannot suppose that the annuity could be bought for less than would be required by the Carlisle Tables.

To find the value of an annuity on a life whose age lies between two of those given in the table, the process must be followed which has been already explained in treating of annuities certain.

An annuity on two joint lives is one which is payable only so long as both the persons on whose lives it is bought are alive to receive it.

TABLE VI.—PRESENT VALUE OR PURCHASE-MONEY OF AN ANNUITY OF 1*l.* ON TWO JOINT LIVES.

Carlisle.—4 p. c.

Age.	0.	10.	20.	30.	40.	50.	60.	70.

50	8·1	7·0	5·3	3·2	1·7			
60	6·2	4·9	3·1	1·6				
70	4·1	2·8	1·5					
80	2·1	1·3						

The preceding Table gives the results of the Carlisle and Northampton Tables on the value of this species of annuity, interest being at 4 per cent. The first column shows the age of the *younger* life, and the horizontal headings are *not* the age of the elder life, but the excess of the age of the elder life above that of the younger. For example, to know the value of an annuity in two joint lives, aged 25 and 55, in which the difference of age is 30 years. In the Carlisle Table, *opposite* to 25, the *younger*, and under 30, the *difference*, we find 10·3; and 8·8 in the Northampton. For the value of an annuity of 100*l.*, the first tables give, therefore, 1030*l.*, and the second 880*l.*

The value of an annuity on the longest of two lives, that is, which is to be payable as long as either of the two shall be alive to receive it, is found by adding together the values of the annuity on the two lives separately considered, and subtracting the value of the annuity on the joint lives. For the above species of annuity puts the office and the parties in precisely the same situation as if an annuity were granted to each party separately, but on condition that one of the annuities should be returned to the office so long as both were alive, that is, during their joint lives. For example, let the ages be 25 and 55 as before, and let the Carlisle Table be chosen, interest being at 4 per cent., we have then :—

TABLE V.—Annuity at age 55	11·3
„ „ 25	17·6
Sum	28·9
TABLE VI.—Joint annuity, 55 and 25 . .	10·3
Difference	18·6

The value, therefore, of an annuity of 1*l.* per annum on the survivor is 18·6*l.*

The value of an annuity which is not to be payable till either one or other of two persons is dead, and which is to continue during the life of the survivor, is found as in the last case, only subtracting *twice* the value of the joint annuity, instead of that value itself. In the preceding case it is 8·3*l.* For this case only differs from the preceding in that the annuity is not payable while both are alive, that is, during the *joint* lives. Consequently the value in this case is less than that in the last, by the value of an annuity on the joint lives.

The value of an annuity to be paid to A. from and after the death of B., if the latter should happen to die first, is the value of an annuity on the life of A. diminished by the value of an annuity on the joint lives of A. and B. For the situation is exactly the same as if the office granted an annuity to A., to be returned as long as both should live. The ages and Table being as before, and the life on whose survivorship the annuity depends being that aged 25, we have:—

TABLE V.—Annuity at age 25	17·6
TABLE VI.—Joint annuity, 25 and 55 . .	10·3
Difference	7·3

whence the value of the required annuity of 1*l.* is 7·3*l.*

The following Table, extracted with abridgment from Morgan on Insurances, deduced from the Northampton Table, with interest at 4 per cent., gives the average sum to which the savings of an individual may be expected to amount at the end of his life, improved at compound interest from the time when he begins to lay by :—

TABLE VII.—PROBABLE AMOUNT OF 1*l.* LAID BY YEARLY, AND IMPROVED TO THE END OF LIFE.

Age.	Amount.	Age.	Amount.	Age.	Amount.	Age.	Amount.
0	137·8	25	79·2	50	29·5	75	7·2
5	159·1	30	66·0	55	23·6	80	4·8
10	137·9	35	54·6	60	18·5	85	3·2
15	114·1	40	44·9	65	14·1	90	2·0
20	94·5	45	36·6	70	10·3		

That is to say, according to the Northampton Tables, if a person were, at the age of 26, (that is, a year after 25,) to begin laying by 100*l.* a-year at interest, he might expect the amount at the end of his life to be 79·2*l.* for each pound laid by yearly; or 7920*l.* Or to speak more strictly, if 100 persons were to do this, they might expect that the average amount of their savings, reckoning the accumulations at their deaths, would be 7920*l.* each. As we have already observed, the mortality of the Northampton Table is greater than the fact, and the average accumulations would be greater, from young ages considerably greater, than those shown in the preceding table.

We have seen that the security of the method for estimating the value of life annuities, depends upon the presumption that the average mortality of the buyers is known. This average cannot be expected to hold good, unless a large number of lives be taken. Therefore, the granting of a single annuity, or of a few annuities, as a commercial speculation, would deserve no other name than gambling, even though the price demanded should be as high as that given in any tables whatsoever.

In the preceding tables, we would again remark, that our object has been simply to furnish the means of giving a moderately near determination of a few of the most simple cases. We should strongly recommend every one not to venture on important transactions, without professional or other advice on which he can depend, unless he himself fully understand the principles on which tables are constructed. The liability to error, even in using the most simple table, is very great, without considerable knowledge of the subject: and most cases which arise in practice contain some circumstances peculiar to themselves, which have not and could not have been provided for in the general rules.

The following references to works on this subject may be found useful. See also MORTALITY; REVERSIONS.

ANNUITIES CERTAIN. 1. Smart's 'Tables of Interest,' &c. London, 1726. There is an edition published in 1780, which is said to be very incorrect. The values for the intermediate half years given in this work are not correctly the values of the annuities on the supposition of half yearly payments; in other respects it is to be depended upon. 2. Corbaux, 'Doctrine of Compound Interest,' &c. London, 1825. 3. Baily, 'Doctrine of Interest and Annuities.' London, 1808. Smart's Tables are republished in this work from the correct edition. Works on *life-annuities* generally contain principles and tables for the calculation of annuities certain.

LIFE ANNUITIES. 1. Price, 'Observations on Reversionary Payments,' &c. Edited by W. Morgan, London, 1812. (Seventh Edition.) 2. Baily, on 'Life Annuities and Assurances.' London, 1810. 3. Milne, on the 'Valuation of Annuities and Assurances,' &c, London, 1815. 4. Morgan, on the 'Principles of Assurance, Annuities, &c., London, 1821. 5. Davies' 'Tables of Life Contingencies.' London, 1825. 6. Finlaison, on the 'Evidence and Elementary Facts on which Tables of Life Annuities are Founded. Printed by the House of Commons, 31st March, 1829,' 7. Gompertz, 'Estimation of the value of Life Contingencies,' in 'Philosophical Transactions,' 1820.

ANNUITY (in Law) consists in the payment of a certain sum, annually calculated, and charged upon the person or personal estate of the individual from whom it is due; if charged upon real estate, it is not an annuity, but a rent-charge. [RENT.] A sum payable occasionally does not constitute an annuity; the time of payment must recur regularly, but it is not necessary that the times of payment should be at an interval of a year; an annuity may be payable quarterly, or half-yearly, or at any other aliquot portion of a year; it may be made payable once in two, three, twenty, or any other number of years.

Under the Roman law, annuities were chiefly created by will, constituting a charge upon the heir in favour of the legatee. ('Dig.,' lib. xxxiii. tit. 1.) In the middle ages they were frequently given to professional men as a species of retainer; and in modern times have been much resorted to as a means of borrowing money. When the person who borrows undertakes, instead of interest, to pay an annuity, he is styled the *grantor;* the person who lends, being entitled to receive the payments, is called the *grantee* of the annuity. This practice was introduced on the Continent with the revival of commerce, when the advantages of borrowing were already felt, but the taking of interest was strictly forbidden. In the 15th century contracts of this kind were decided by the popes to be lawful, and were recognised as such in France, even though every species of interest upon money borrowed was deemed usurious. (Domat's 'Civil Law,' part i. b. i. t. 6.) The commercial states of Italy early availed themselves of this mode of raising money, and their example has since been followed in the creation of the national debts of other countries. [NATIONAL DEBT; STOCKS.]

An annuity may be granted for a term of years, for the life or lives of any persons named, or in perpetuity; and in the latter case (though as in all others, the annuity as to its security is personal only) it may be granted to descend in the same manner as real property; and hence such an annuity is reckoned among incorporeal hereditaments.

A perpetual annuity, granted in consideration of a sum advanced, differs from interest in this, that the grantee has no right to demand back the principal sum; he must be content to receive the annuity which he has purchased. But the annuity is in its nature redeemable by the grantor, who may discharge himself from any further payments by returning the money borrowed. It may however be agreed between the parties (as it generally has been in the creation of our own national debt, which consists chiefly of annuities of this sort) that the redemption shall not take place for a certain number of years.

An annuity for life or years is not redeemable in the same manner; but it may be agreed by the parties that it shall be redeemable on certain terms; or it may afterwards be redeemed by consent of both parties. Where the justice of the case requires it (as where there has been fraud, for instance, or the bargain is unreasonable), a court of equity will decree a redemption. When such an annuity is granted in consideration of money advanced, the annual payments may be considered as composed of two portions; one being in the nature of interest, the other as a periodical return of a part of the principal, so calculated, that when the annuity shall have determined, the whole of the principal will have been repaid. Annuities for life or years, being the only security that can be given by persons who have a limited interest in property, are frequently granted in consideration of a loan. Besides this advantage, annuities for life, inasmuch as they are attended with risk, were not within the reach of the usury laws, and were therefore, while these laws were in force, constantly used in order to evade them. The legislature was then driven to require that certain formalities should be observed in creating annuities. By statute 53 Geo. III. c. 141, s. 1, every instrument by which an annuity is granted was made null and void, unless within thirty days after execution thereof a memorial was enrolled in Chancery. If any part of the consideration money was returned, or paid in notes which were afterwards cancelled, or retained on pretence of answering future payments; or if the consideration being expressed to be paid in money, was paid in goods, the person charged with the annuity (that is, the borrower) might, if any action were brought against him, by applying to the court have the instrument cancelled (s. 6). The statute also enacted that every contract for the purchase of an annuity made with a minor should be utterly void, and should remain so, even though the minor, on coming of age, should attempt to confirm it (s. 8). The provisions of this act were intended to be confined to cases where the annuity was granted in consideration of a loan. It was amended and explained by the 3 Geo. IV. c. 92, and 7 Geo. IV. c. 75; but all the usury acts, of which this might be termed one, have been repealed (17 & 18 Vict. c. 90), and parties are now left perfectly free to make their bargains in the terms they think fit.

Annuities may be, and frequently are, created by will; and such a bequest is considered a general legacy, and, in case of a deficiency in the estate of the testator, will abate proportionably with the other legacies.

An annuity may be charged either upon some particular fund (in which case, if the fund fails the annuity ceases), or upon the whole personal estate of the grantor, which is usually effected by a deed of covenant, a bond, or a warrant of attorney. If the person charged with the payment of an annuity becomes bankrupt, the annuity may be proved as a debt, and its value ascertained. (Bankrupt Law Consolidation Act, 12 & 13 Vict. c. 106, s. 175.) Sureties for the payment of it by the bankrupt may also prove (s. 176). The value of the annuity becomes a debt upon the estate of the bankrupt.

If the person on whose life an annuity is granted, dies between two days of payment, the grantee has no claim on him in respect of the time elapsed since the last day of payment. From this rule are excepted annuities granted for the maintenance of the grantee. On government annuities, a quarter's annuity is paid to the executors of an annuitant, if they come in and prove the death. [APPORTIONMENT.]

ANNUITY (in the Law of Scotland). The 53 Geo. III. c. 131, did not extend to Scotland. In that country a fixed sum per annum paid periodically, secured on heritable property, is called an annuity: grants of annuity on personal security are, however, almost unknown. An annuity is generally granted for life: and it may either be created by reservation in a transfer of the property, thus constituting a burden on the new proprietor's title; or it may be granted by the proprietor, the annuitant making his title real, as in the case of an absolute estate in land, by seisin. Provisions to widows and children are thus secured. This species of security on land is to be distinguished from right of annual-rent, which was formerly the mode in which the payment of the interest of money lent on heritable security was made a real burden on the lands, before the modern and more effective security was devised of taking a redeemable conveyance of the lands themselves to the creditor. When the obligor or grantor of an annuity became bankrupt, there was no statutory provision in Scotland for enabling the annuity creditor to prove. The Court of Session was in use to interpose equitably to allow the annuitant to draw a dividend on the value of the annuity. Provisions for the valuation of annuities, and as to the claims of the sureties for its payment, are made by the recent statute 19 & 20 Vict. c. 79. The Act for the amendment of the law of entail in Scotland (11 & 12 Vict. c. 36) enables heirs of entail to grant bonds of annual-rent for the value of the improvements effected by them (ss. 13 & 14). These annual-rents may be made payable for 25 years after the death of the grantor.

ANNUITY (WRIT OF). A writ which lies for the recovery of an annuity, but which is in practice now obsolete (Fitzherbert, 'Nat. Brev.' 356). When annuities are granted, there is always a covenant for payment by the grantor, on which the grantee may sue in covenant.

ANNULET, in architecture. This term is applied to the small eccentric rings or bands which enrich the lower part of the moulding of the Doric capital, just where it falls into, or grows out of, the top of the shaft, or trachelium. It is formed from the Latin word signifying a ring.

AN'NULUS, the geometrical name of a ring, or solid formed by the revolution of a circle about a straight line exterior to its circumference as an axis, and in the plane of the said circle.

To find the surface of a ring, measure the interior and exterior diameters in feet or inches, &c. Multiply together the sum and difference of these diameters, and multiply the product by 2·4674011, taking as many decimals as may be thought necessary. For common purposes, it will be sufficiently exact to divide 200 times the product of the sum and difference twice successively by 9. If still greater correctness be required, subtract from the last result its 500th part. The result will be the number of *square* feet, or inches, &c., in the surface of the ring.

To find the solid content of a ring, measure the outer and inner diameters as before, multiply together their sum and the square of their difference, and multiply this product by ·3084251. For common purposes, it will be sufficient to annex three ciphers to the product of the sum and the square of the difference, and to divide by 3242. The result will be the number of cubic feet or inches, &c. in the ring.

ANNUS DELIBERANDI, in the law of Scotland, is the year immediately following the death of the proprietor of heritable property, which is allowed to the heir that he may make up his mind whether he will accept the succession with the burden of his predecessor's debts. Within that time he cannot be compelled to adopt an alternative, unless he has expressly or virtually resigned the privilege. The practice is adopted from the title of the Pandects ('De Jure Deliberandi,' xxviii. tit. 8). The term of a year was fixed by a constitution of Justinian ('Cod.' vi. tit. 30, s. 19).

ANODY'NES, from the Greek word ἀνώδυνος (*anódunos*), which sometimes signifies, "that which relieves from pain." We may consider pain as an intimation of some derangement of the system, the continuance of which would be hurtful. It therefore prompts us to take measures to remove the causes of it, which being done, the pain generally ceases. But as pain itself, from the inconvenience and suffering which it occasions, frequently aggravates the disease of which it is the accompaniment, it becomes necessary to employ means to lessen or suspend it, even though we should not be able to control the disease: these means are termed *anodynes*, and are either applied externally, or given internally.

The seat of pain is evidently in the nervous system, but its cause and origin appear to be intimately connected with the state of the circulating system, particularly with the quantity of blood contained in the arteries, and the degree of force and rapidity with which it passes through them. Hence pain may be said to be of two kinds; that which occurs when the blood stagnates in the extreme vessels, or capillaries, while the larger vessels propel it with increased force, or the state termed *inflammation*; and that which occurs when there is a deficiency of blood in the extreme vessels, from the action of the large vessels being too feeble to propel it, as happens after long abstinence from food, or other causes of exhaustion—such as prolonged suckling of infants by mothers. The discrimination of these two kinds of pain is of great practical importance; for while the first will be relieved by bleeding and anodynes, the second will be greatly aggravated by the employment of either of these means. It is therefore to the former that the use of anodynes must be limited, in which they appear to be productive of benefit in two ways; first, by rendering the nerves of the part less sensible; and, secondly, by diminishing the violence with which the large vessels propel the blood, when the anodynes are given in sufficient quantity to influence the brain, and through it, by a process extremely complex, which we need not explain here, the contractile power of the heart and arteries. As most of the articles termed anodynes have a powerful influence over the brain, they generally produce sleep, if given in a large dose; hence they are also denominated *hypnotics*; and from causing insensibility, they are also denominated *narcotics*. The knowledge of their possessing this power should lead us to observe great caution in their administration, lest by an over-dose we should produce a fatal coma, or very profound sleep, from which the patient might never be roused.

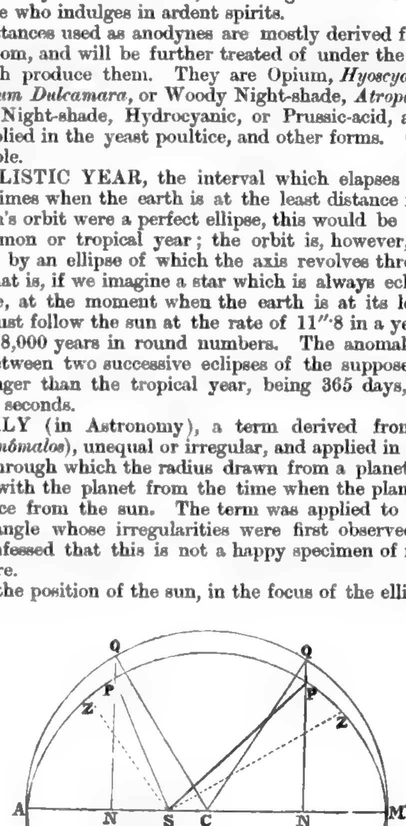
It deserves also to be mentioned, that their frequent repetition produces an injurious effect on the frame, particularly on the nervous system, and function of nutrition; we should therefore carefully guard against acquiring a habit of having recourse to them on slight occasions, or without the sanction of a competent authority. The opium-eater not less certainly induces disease, and brings himself to an untimely end, than he who indulges in ardent spirits.

The substances used as anodynes are mostly derived from the vegetable kingdom, and will be further treated of under the names of the plants which produce them. They are Opium, *Hyoscyamus*, or Henbane, *Solanum Dulcamara*, or Woody Night-shade, *Atropa Belladonna*, or Deadly Night-shade, Hydrocyanic, or Prussic-acid, and Carbonic-acid-gas applied in the yeast poultice, and other forms. Chloroform is most valuable.

ANOMALISTIC YEAR, the interval which elapses between two successive times when the earth is at the least distance from the sun. If the earth's orbit were a perfect ellipse, this would be exactly equal to the common or tropical year; the orbit is, however, more nearly represented by an ellipse of which the axis revolves through 11″·8 in a year. That is, if we imagine a star which is always eclipsed by the sun's centre, at the moment when the earth is at its least distance, that star must follow the sun at the rate of 11″·8 in a year, or a revolution in 108,000 years in round numbers. The anomalistic year, or the time between two successive eclipses of the supposed star, is 25 minutes longer than the tropical year, being 365 days, 6 hours, 13 minutes, 45 seconds.

ANO'MALY (in Astronomy), a term derived from the Greek ἀνώμαλος (*anômalos*), unequal or irregular, and applied in astronomy to the angle through which the radius drawn from a planet to the sun, has moved with the planet from the time when the planet was at its least distance from the sun. The term was applied to this angle, as being the angle whose irregularities were first observed; though it must be confessed that this is not a happy specimen of mathematical nomenclature.

Let S be the position of the sun, in the focus of the ellipse described



by the planet, A the *perihelion*, or point of least distance from the sun, A P M the ellipse described by the planet, A Q M the circumscribed circle, P the place of the planet, and Q P M a perpendicular to the axis A M. Let C be the centre of the ellipse and circle. The planet moved quickest at A, and slowest at M. Conceive a fictitious planet Z to move round the ellipse A P M, with the average motion of the real planet, so as, without varying its motion, to make the angle A S Z increase uniformly, and to describe the whole revolution in the same time as the real planet. Then, for the moment when the planet is at P, the angle A S P is called the *true anomaly*, A S Z is called the *mean anomaly*, and A C Q the *eccentric anomaly*. In speaking of the sun or the moon, it is the earth which is supposed to be at S, and the sun or moon at P. Also, in speaking of the satellites of Jupiter or Saturn, the planet is supposed to be at S, and the satellite at P. For a double star, one star is supposed to be at S, and the other to revolve round it.

The determination of either two anomalies from the third, is a problem of considerable difficulty, the discussion of which may be found in any mathematical work on astronomy.

ANTACIDS, from the Greek word *anti*, against, and the Latin word *acidum*, an acid, signify means used to correct acidity in the stomach. Though hydrochloric acid (formerly called muriatic acid, or spirit of salt) is present in a free state in the stomach during the process of healthy digestion, yet under particular circumstances it is apt to be generated in excess; so also lactic acid. Other acids, such as butyric, acetic, carbonic, &c., are also occasionally evolved in the stomach, probably from the fermentation of the articles, as vegetables and fruits of different kinds, by which the acetic acid is produced, or introduced ready formed, in wines or hard beer; and in certain vegetables, as sorrel, which contains oxalic acid. The most frequent source of acidity is that first mentioned, the secretion of acid by the vessels of the stomach. It is therefore dependent upon constitutional causes, or the state of the system generally. This is further proved by considering what kind of persons are most subject to it; these are individuals either naturally of a feeble and weak constitution, or who have weakened the stomach and system generally by excessive indulgence in *good living*, as it is termed, that is, too much animal food and wine, unaccompanied by exercise and other counteracting measures. Hence, we see these persons, or their children, and even their children's children, subject to gout or gravel, and stone in the bladder. As it has been ascertained (see the works of Mr. Murray Forbes, 'A Treatise on Gravel and Gout,' 1786; Wilson Philip, Marcet, Blane, Prout, and Majendie) that these painful diseases have their origin in the tendency of the stomach to the formation of an excess of acid, an inquiry into the causes of this and the circumstances under which it takes place, is of great importance as a means of preventing or counteracting them.

When an excess of acid is introduced into the blood it occasions much irritation of the system generally, and the composition of the blood being different from its natural constitution, the secretions formed from it are unhealthy, proving a further source of disease. In consequence of the composition of the blood being altered, matters usually held in solution by it can no longer be kept in that state, but are precipitated; hence we have *chalk stones*, as they are termed, formed around the joints in gout, and calculi, or *stones* of different kinds, in the kidney or bladder.

The signs or symptoms of acid being in excess are not in general limited to the stomach, but show themselves in several parts of the body. There is heartburn (cardialgia), often followed by eructation and rejection by the mouth of a fluid so extremely acid as to cause effervescence when it falls on a marble stone; the urine generally scanty and high coloured, from which, on standing, a sediment falls down; the skin dry, harsh, and often affected with eruptions of different kinds; and the mind of the patient fretful, and much given to take gloomy views of his health or circumstances,—in short, decidedly hypochondriacal.

The medicinal means of remedying this state are all alkaline, either the pure alkalies or some combination of them, such as solution of potash, or carbonates of soda, potash, magnesia, ammonia, or lime. Where the bowels are not disordered, but the urine denotes that the excess of acid mostly finds an outlet by that channel, the preparations of potash and soda are to be preferred. Where the bowels are much confined, magnesia or its preparations may be given in conjunction with rhubarb. Nothing is more hurtful than the frequent use of magnesia alone, it being apt to accumulate in the bowels. In the case of an individual much addicted to its use, a mass of it was found after death lodged in the large intestines, which weighed six pounds. If, on the other hand, the bowels be in a loose state, prepared chalk may be given with advantage, or lime-water, which is a very useful addition to milk where, from excess of acid, it disagrees, and hence most serviceable for weak children. Should the mind be much depressed, or general languor of the system exist, and no state of stomach be present forbidding its use, ammonia in some form may be exhibited.

Such are the medicines by which the effects of an excess of acid may be in some degree counteracted; but the most efficient means of preventing its formation consist in a strict attention to diet and regimen. Great moderation must be observed in the quantity as well as quality of the food and drink. The plainest and most digestible animal food should be taken once, or at the utmost twice a day, and sparingly. Hard-boiled puddings and dumplings must be avoided. Toast and water, or soda-water, or well-fermented beer, or cyder, are preferable as drinks to wine or ardent spirits; the only one of which last that can be allowed is Hollands, and never but under particular circumstances, and with the sanction of a medical adviser.

Regular exercise, friction, and every means, such as flannel next the skin, which can keep up a free action of the skin, form a most important part of the prophylactic treatment.

ANTÆ. This is a term used by architects to designate the pier-formed ends of a wall, as in the terminations of the lateral walls in a Greek temple, where a plain face returns on each side, having some relation in general proportion to the columns with which they compose. The antæ (for the word is used alike in the singular and in the plural) has a moulded and otherwise enriched cap or cornice, and generally a moulded base. In the simple Greek Doric style or order, both the cap and the base-moulding are of few parts, and the enrichments are few, and are confined to the mouldings, which may be either carved or painted; but in the more ornate Ionian or voluted style, both the cap and base of the antæ are in proportion deeper, are in a greater number of parts, and have extrinsic ornaments, besides the carving or painting of the mouldings of the cap, and the fluting or reeding of those of the base. The antæ of the foliated or Corinthian style admits of still further enrichment, though the bold foliage and diagonal volutes of the capital of the column should never be placed on the square faces and sharp angles of the antæ. The moulded caps and bases of antæ are, in Greek works, generally continued along the flank walls so as to form the cornice and base of the whole wall, and not of the protruded faces of its ends alone. In Roman works, and in modern imitations of both, breaks are often made on the face of a wall with the caps and bases of antæ, but more frequently with those of columns, and these are called pilasters, though indeed they are but an abuse of the Greek *parastas*, or antæ. In classical Greek, and in the best Roman works, antæ and pilasters are never either diminished or fluted. [TEMPLE.]

ANTAGONIST MUSCLE, from ἀντί, against, and ἀγωνίζομαι, to strive—a muscle, the action of which is opposed to that of some other muscle. Muscles are the instruments by which, in the animal body, motion is effected. The object of each muscle is to produce some specific motion: among the various motions which are needed in the animal economy, it necessarily happens that some are directly opposite to others, and the muscles which accomplish these directly opposite movements are said to be with relation to each other *antagonists*. When any part of the body is placed between muscles which have an opposite or antagonising action, the result of the combined action of such muscles is to keep that part steadily in a certain position. The form and position of the human mouth, for example, are maintained, such as they are, in a state of health and during repose of the features, by a number of muscles, composing the lips and cheeks, the action of some of which is directly contrary to that of others: the natural figure and position of the mouth may, therefore, be truly said to be the result of the combined action of a number of antagonising muscles. The consequence of the disturbance of this antagonising action is to change the natural form and position of the mouth. This is shown by the effect of paralysis when it affects one side of the face. Paralysis is a disease depriving the muscle of its power of acting. In paralysis of one side of the face, the muscles of that side are deprived of their power of acting; and the consequence is, that the muscles of the other side, which retain their usual power, pull the mouth to their side, because they do not meet with the resistance which formerly opposed their effort to do this. Hence comes distortion of the mouth; and distortion is one of the most frequent and striking signs of apoplexy and paralysis, a sign dependent, it is obvious, on the loss of the antagonising power of the muscles of that part of the body in which the distortion takes place. Sometimes the elasticity of a part is put in opposition to a muscle, and becomes the antagonising power. The elasticity of the ribs, of the windpipe, of the arteries, may be so considered.

ANTALKALIES, from *anti*, against, and *alkali*, an alkali, are means of counteracting the presence of alkalies in the system. An alkaline condition of the system is not an unusual occurrence, and leads, when long continued or extreme, to very serious consequences. The worst of these is the formation of those calculi or stones in the bladder denominated *phosphates*. A tendency to this state exists in most weak individuals: hence, most commonly in children, old persons, and females. It may also be brought on by any cause which occasions either temporary or general debility. The prevalence of the depressing passions, as fear, anxiety, or any other which keeps up a *nervous state* of the system, the frequent and continued use of mercury, of powerful purgatives in sickly frames, injuries of the back, or the previous existence of a very acid state of the system, will occasionally give rise to an alkaline state of the system, which, when considerable, shows itself by great general debility, pale countenance, deranged state of the stomach and bowels, and excessive secretion of urine of a pale colour, which, on standing, makes a white deposit. To cure and prevent the return of such a state, the causes must, as far as possible, be removed. This is best done by diet, regimen, and appropriate medicines. The diet should be nourishing, mostly animal food, but taken in moderation; and where wine is used, light French or Rhenish should be preferred; hard water should be carefully avoided; saline purgatives, as Rochelle salts or seidlitz powders, and indeed all combinations of a vegetable acid with an alkaline base, such as the common saline draught, must be abstained from. The irritability of the system is best lessened by opium and tonic medicines. These last furnish an excellent vehicle for the administration of acids, which are the most fitting medicines, either muriatic, nitric, or the citric acid, which is most grateful to children. The phosphate of iron is also a very useful medicine. Purgatives of an active kind should seldom be given; but when the stomach and bowels of children are much disordered, calomel and rhubarb taken frequently for some time are of much service, especially when the phosphate of iron is employed at the same time. Pure, invigorating air, and moderate exercise, are very beneficial, with relaxation from too great mental exertion, where this has preceded the disease.

ANTARES, a name given to the bright star marked α in the constellation SCORPIO, which see. In the latitude of Greenwich, it has not more than $12\frac{1}{4}°$ of altitude when on the meridian, where it is at midnight in the beginning of July. In 1846, this star was discovered to be double by Professor Mitchell, of Cincinnati, U.S. According to Mr. Dawes, the two constituent bodies were about $3''\cdot 4$ apart in the year 1848.

ANTECEDENT, a mathematical term used in proportion, meaning the *first* of the two terms of a ratio, in opposition to the *consequent*, or second term. Thus, in the continued proportion :—

$$2 : 4 :: 3 : 6 :: 4 : 8 :: 5 : 10, \&c.$$

2, 3, 4, 5, &c., are antecedents; 4, 6, 8, 10, &c., are consequents. Antecedents may be made consequents, and consequents antecedents without altering the truth of the proportion. Thus, if

$$a : b :: c : d,$$

it is equally true that

$$b : a :: d : c.$$

ANTECEDENTIA. When a heavenly body moves contrary to the order of the signs of the zodiac—from Gemini to Taurus, from Taurus to Aries, &c.—it is said to move *in antecedentia*. When it moves according to the order of the signs, it is said to move *in consequentia*.

ANTEFIXA, or ANTEFIXÆ, for this term is more frequently used in the plural, for both singular and plural, than otherwise. Antefixæ are blocks with vertical faces placed along the top of a cornice in ancient Greek and Roman buildings, to hide the ends of the covering or joint tiles, and their faces are generally carved with a flower, leaf, or other enrichment, to make them ornamental. The lions' heads and masks sometimes carved or fixed on the upper mouldings of cornices, which serve as spouts to carry off the water, are also called antefixæ. Several terra cotta antefixæ of very beautiful design, from Rome, are in the British Museum. The flanks and rounded projection from the eastern end of the church of St. Pancras, in London, exhibit antefixæ ranged over the cornice, but without the parts of which they are the fitting accompaniments. The Pall Mall and Carlton Gardens fronts of the Travellers' Club House, in London, show antefixæ more judiciously composed with the roof, with which they form an ornament to, and help to enrich, the elevation.

ANTEPAGMENTA. This is an ancient term for the jambs of a door, or, as they are familiarly termed, the door-posts.

ANTHELMINTICS, from two Greek words, signifying means used to expel worms from the intestinal canal, and to prevent their formation. Though the origin of worms in the intestines has been a subject of inquiry and controversy for many ages, we are far from having arrived at a satisfactory conclusion respecting it. While some have regarded them as the result of what is termed *spontaneous* or *equivocal generation* occurring in the intestines (see Aristot. 'Hist. Anim.' v. 19), others have maintained that they are introduced into the stomach from without, either along with our food, or in some other way, in so small a form as to be unobserved. Great difficulties attend either view of the question. If it is held that they come from without, the sources of them have never been seen, and cannot be pointed out. The opinion of their spontaneous generation is also rendered very improbable, both by the consideration that such an occurrence would be at variance with the present universal mode of production of all other animals, which invariably issue from parents similar to themselves, and by the fact that, however the worms may be at first produced, when once developed in the intestines, they are propagated like other animals of the same grade in the scale of organisation, namely, by parents of distinct sexes; and the *ova* or *eggs* which the female produces are both to be seen in the oviducts (see fig. 1, *a*), before they escape, and also are to be found among the contents of the intestines previous to their development as perfect worms. The settlement of this question would be interesting, and might prove useful in directing us in our prophylactic treatment. But as we cannot pretend to this in the present state of our knowledge, we must refrain from further discussion of the subject, and rather inquire into the circumstances and conditions favourable to their development and the means of counteracting them.

The causes of worms, and of the tendency to their formation, may be divided into, 1, general and local, referring to the residence; and, 2, special, referring to the individual infested by them, his constitution, habits, diet, &c.

Of the first division, the most general is climate. In certain countries worms prevail more than in others; and hence their frequency in Holland, where there is no want of personal cleanliness, or attention to the food; but the constant moisture of the atmosphere, both producing general weakness, and acting hurtfully on the skin,—the state of which, owing to the sympathy existing between it and the digestive organs, influences greatly the health of the body,—farther predisposes to their development. We see the same causes operate in producing the rot in sheep, which is always accompanied by the presence of a worm (the *Distoma hepaticum* or *fluke*) in the liver; and we shall find the same means prove successful in preventing their formation in both cases: as only sheep feeding in wet pastures, such as marshes, are subject to the rot.

Dwelling in an impure air, where there is not sufficient ventilation, prepares the body for becoming the seat of worms, and hence their greater frequency among the crowded inhabitants of towns than among the peasantry.

The effect of these general causes is to produce a weak state of the system, the existence of which, however occasioned, seems the first requisite for the development of worms. When in addition to these there are other causes which operate only on individuals, we perceive the reason why one person becomes subject to worms, from which another person continues exempt. This naturally conducts to the second set of causes, connected with the individual affected by these parasites. These we shall find to be a constitution, either hereditarily weak, or debilitated by sedentary occupations and improper diet. Accordingly, those most subject to worms are females and children, especially of a scrophulous habit. In these last there exists very commonly weakness of the digestive organs, along with an immoderate craving for food, which injudicious parents and nurses are too apt to indulge—regarding it as the sign of a good appetite—by which more aliment is introduced into the stomach than it can conveniently digest, and consequently the stomach and bowels become clogged, both by the undigested matters remaining in them, and also by the unhealthy secretions, which, under such circumstances, are invariably poured into them. The articles given to satisfy this craving, which generally shows itself between meals, are almost always those which experience has shown to be the most calculated to favour the production of worms, namely, articles of too farinaceous a kind, as biscuits, cakes of different sorts, or bread and butter, or cheese: for milk, and the preparations of it, which we have just mentioned, seem to dispose to the formation of worms more decidedly than anything else.

The presence of worms in the intestines cannot always be determined by any one, or even by the concurrence of many symptoms, for enormous tænias (*tape worms*) have sometimes been passed, of the existence of which not the least suspicion was entertained by the individual; nor was any derangement of the health observable. But we are justified in suspecting them to be present where the appearance and expression of the countenance are much altered from the natural state; when it is of a pale, somewhat leaden, hue, subject to sudden flushings, often limited to one side of the face, where the eyes have lost their brightness, the pupil is enlarged, and the lower eyelid surrounded by a livid circle. In addition to these symptoms, the nose is often swollen, and affected by an intolerable itching, or frequently bleeding; there are pains in the head, with ringing of the ears; the tongue is coated, and the breath disagreeable. The appetite is very variable, sometimes there is none, at other times it is ravenous: there is often a feeling of sickness and a disposition to vomit; occasionally there are violent cholics, the bowels irregular, seldom costive, more frequently loose; the stools slimy, sometimes tinged with blood; the belly swollen and hard, while there is generally a wasting of the rest of the body; the urine is rarely clear, often of a milky appearance. The sleep is disturbed, and the child grinds the teeth; during the day, it is indolent, and very variable in temper.

It is necessary to be thus minute in stating the symptoms of worms, as, sometimes on very slight grounds, individuals have been subjected to a long and severe course of treatment for worms, when none existed; while, too often, they are allowed to commit their ravages unmolested, and to plunge the unhappy victim into a state of great misery and suffering, and even lead to a fatal termination. We are not willing to attach full credit to all the horrible consequences attributed to worms, but that they often produce many serious diseases, and aggravate others, is certain.

The number of different kinds of worms infesting the stomach or intestines of man is not very great, but they propagate their species often with astonishing rapidity. We shall enumerate the most common sorts, following the nomenclature of Bremser, ('Lebende Würmer in lebenden Menschen.' Wien, 1819; also translated into French, by Dr. Grundler, Paris, 1828. 'Traité des Vers Intestinaux.')

The *Trichocephalus dispar* (or *long thread worm*), found in the upper part of the large intestines (or *Cæcum*); *Oxyuris vermicularis* (*Ascaris vermicularis*, the *maw*, or *thread worm*), which inhabits the rectum, or lowest intestine; *Ascaris lumbricoides* (the large round worm), mostly found in the small intestines; *Bothriocephalus latus* (*Tænia lata*, the *broad tape-worm*), found in the small intestines (principally of the inhabitants of Russia, Poland, and Switzerland, seldom met with in Britain); *Tænia solium* (the *tape-worm*), in the small intestines, generally alone, but occasionally three or four together: the *Distoma hepaticum* (or *fluke*), is sometimes found in the liver and gall-bladder of man, but more commonly of sheep, goats, &c.

The worms which are occasionally found in other parts of the body are not under the influence of the medicines termed *anthelmintics*, and we therefore leave them unnoticed here.

To assist us in distinguishing the particular kind of worm present in the intestinal canal, and to regulate thereby our treatment, it is proper to mention that the maw, or thread worm, and large round worm, are most common in youth, and the tape-worm in adult age.

From what has been said above, the principles of treatment may readily be deduced: these are, to strengthen the individual, and weaken the worms, which facilitates their expulsion, and diminishes the tendency to their formation. This last is a point of great practical importance; for not only is it of little use to expel worms already existing in the intestines, unless we remove the tendency or disposition to their production, but, very frequently, many of the articles inconsiderately administered (which however are regarded as valuable anthelmintics, because, by their operation, they bring away worms), often do more harm to the individual who takes them than to the worms. It is clear that all articles which by their sharp angles merely irritate the worms must do much more injury to the inner coat of the stomach and intestines, and cannot possibly be introduced or insinuated between the mouths of the animals and the surface to which they are attached. The woodcut (*fig.* 4) shows by what a number of hooks the *tape-worm* attaches itself to the gut. When we see these, need we wonder at the difficulty of expelling this formidable and most determined parasite?

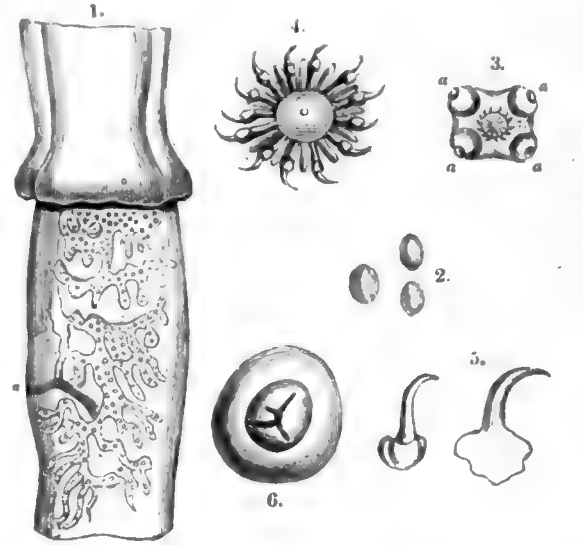
The means employed to effect the ends proposed are very numerous, but reducible to three heads: namely, those which by increasing the peristaltic motion of the intestines, displace the worms, and often occasion their expulsion, as purgative medicines of different kinds; those which tend to increase the strength of the stomach and intestines, and system generally, as tonics, or analeptics; and lastly, those which are conceived to act in an especial manner on the worms, dislodging, weakening, or killing them—or anthelmintics, in the strict sense of the word. Our means must be varied, for not only are the different kinds of worms limited to different parts of the intestinal canal, and the species of worms infesting it different at different periods of life, but particular substances are found to be more efficacious against one species than against others.

As a part of the general treatment of worms, purgatives are indispensable, and those should be selected which bring away the greatest quantity of slime; but the frequent repetition of such is inexpedient. Calomel with jalap, or scammony may be given, with the interval of two days between each dose, two or three times, followed by tartrate of antimony in very small doses for a week: this may be succeeded by aloes, with antimonial powder, which last being laid aside, preparations of iron alone, or with gentian and canella, may be united with the aloes. This plan may be pursued, whatever be the kind of worm supposed to be present, being merely intended to improve the general health of the patient. When the strength is somewhat increased, cold, which is very pernicious to the worms, may be added to our means of cure, and employed in various ways. Large quantities of cold water, rendered still colder by dissolving in it, immediately before drinking, a quantity of table-salt, or muriate of soda, may be taken. Sea-water may also be drunk with great benefit.

Among our purgative means we must not omit to mention sulphate of potass and rhubarb, to which if there be nervous symptoms present, such as a tendency to epilepsy or hysteria, valerian may be advantageously added. Different mineral waters are of great service, particularly in the treatment of the maw-worm. These both remove the slime in which the worms nestle, and diminish the tendency to its formation. With this view we may have recourse to the waters of Cheltenham, and above all, to the sulphureous springs of Harrogate, followed by chalybeates there, or at Tunbridge.

The means of strengthening the digestive organs, consist of tonic and astringent medicines, both vegetable and mineral. Vegetable bitters are doubly advantageous, since they both strengthen the stomach, and prove direct poisons to the worms: of these, the best are chamomile tea, and infusion of quassia, or gentian, to which muriatic acid, or tincture of muriate of iron may be added; for children the tartrite of iron, being almost tasteless, is advisable. The utility of vegetable bitters is proved by the fact, that wherever the *Menyanthes trifoliata* (*bog-bean*), or the tormentil, grows, however damp the pastures may be, the rot never infests the sheep. A similar immunity from the rot is generally enjoyed by sheep fed on the salt marshes, or where salt is regularly mixed with their food. (See 'Reports of Lord Somerville.') The omission of a proper quantity of salt with our food favours the engendering of worms. The great tendency to the formation of worms in Holland has been mentioned, and when the "ancient laws of that country ordained men to be kept on bread alone, *unmixed with salt*, as the *severest* punishment that could be inflicted upon them in their moist climate, the effect was horrible; the wretched criminals are said to have been *devoured by worms*." The medicines enumerated constitute the most effectual means of preventing the return of worms; those which follow are deemed the best for expelling particular kinds of worms. The tape-worm (*Tænia solium*) is almost invariably expelled dead, by a large dose of oil of turpentine; and even the *long round worm* is influenced by it in somewhat smaller doses. Scarcely any other article need be employed, unless the disagreeable smell and taste be objected to, when the *Brayera anthelmintica*, Kousso, should be given as at once safe and efficacious: we might naturally expect this result, since it belongs to the same natural family tribe as the tormentil, namely, the *Rosaceæ*. The root of the pomegranate is much esteemed in India. No reliance should be placed on the root of the male fern, as it is only useful against the *Bothriocephalus latus*, or *broad tape-worm*, which, though common in Switzerland, is rare in Britain.

The *long round worm* is almost invariably expelled by the *Spigelia Marylandica*, or Indian pink, which belongs to the same natural family as the bog-bean, or water trefoil, namely, the *Gentianæ*. The *Oxyures*, or maw-worms, are the most troublesome to the patient, and the most difficult to remove, as medicines taken by the mouth are too much altered before reaching the rectum to produce any great effect; compound chalk powder, which contains tormentil, is very useful. After the employment of the above-mentioned general measures, we should use local means only. The intolerable itching which they occasion about the rectum, is best relieved by a lavement of sweet-oil. A lavement of very cold water, or lime-water, may be useful, if, after it, a portion of aloes be introduced, and left to dissolve in the bowel. Injections of tobacco, and the use of all such dangerous articles as bear's-foot (*Helleborus fœtidus*), are to be avoided. The same may be said of tin-filings, cowhage, and all things which can act only as mechanical irritants.



1. Two joints of the *Tænia solium*, tape-worm, magnified, in one of which are seen the numerous ova, or eggs. *a*. The oviduct by which they pass out. 2. Some of the eggs, much magnified. 3. Head of the animal, seen in front to show the mouth in the centre, surrounded by a circle of hooks, and the four suckers, *a*, *a*, *a*, *a*, of which two are alternately protruded, and two retracted. 4. The mouth with its hooks. 5. Two of the hooks, very greatly magnified. 6. A sucker, much magnified.

ANTHEM, in music, was originally a simple hymn, or kind of psalm-tune, sung alternately by the two sides of the choir. The term is now, however, applied to compositions in use in all our choirs, set to verses from the Psalms, or to any portion of the Scriptures or Liturgy; and the anthem may be for one, two, or any number of voices, but rarely exceeds five parts. [ANTIPHONY.]

There are three kinds of anthem, namely, verse; full, with verse; and full. The first, which is solo, or duet, &c., has only one voice to a part, and, requiring nicety of execution, is generally assigned to the best singers in the choir. The second, consisting chiefly of chorus, is sung by the whole choir, but the verse parts by single voices. The third is chorus wholly, and performed by all the voices.

The English school has always excelled in the composition of anthems. Tallis led the way in full anthems, and was immediately followed by Birde and Farrant. Their harmony is quaint, but indescribably solemn, and in true keeping with the Gothic structures wherein it was first heard. Orlando Gibbons soon succeeded those masters, and in the same kind of anthem—but highly elaborated, and enriched with whatever florid counterpoint could supply—brought forth works that have always been, and must ever continue to be, admired, not for their ingenuity only, but their effect. Blow was one of the first to introduce the verse anthem, but his compositions, dry and stiff, are become nearly obsolete. Purcell, his pupil, produced numerous anthems, some few of them exhibiting striking beauties, and much grandeur of conception; but the majority, being written in the manner of his master, are more learned than pleasing. Michael Wise and Jeremiah Clark made our cathedrals acquainted with natural and pathetic melody. Croft, Greene, Boyce, and Nares, in anthems of all the three species, united air and harmony, genius and learning, in a manner unequalled; though it is to be regretted that their works are little known, except where choir service is performed, and seldom heard, in our parochial churches and other places of worship.

A'NTHEMIS NO'BILIS (COMMON or ROMAN CHAMOMILE)—*Medical Properties of.* This is an indigenous plant, frequent on our commons; but the flowers used in medicine are generally obtained from cultivated plants. Of these there are two kinds, the single or semi-double, and the perfectly double. The doubling of the flowers is attended with a lessening of their virtues, as the single are more aromatic, and contain more volatile oil, which resides in the yellow tubular florets of the disk. Their excellence may be determined by the beautiful whiteness of the radiant florets, the yellowness of those of the disk, and the strength of the aroma and taste.

Those which are brown, mouldy, and faintly smelling, should be rejected. They contain a volatile oil of a beautiful blue colour, camphor (?), a gum resinous principle, and a small quantity of tannin.

The difference both of taste and smell, the diversity of the oil, and the absence of the camphor-like principle, show the impropriety of substituting for the *Anthemis* the flowers of the *Matricarica Chamomilla* (or Feverfew). In this genus the receptacle is naked, in the *Anthemis* it is paleaceous,—besides, the flowers are smaller, and of an unpleasant smell. The flowers should be gathered before they fully expand. The forms of exhibition are, powder, infusion, extract, and oil.

Chamomile is an excellent bitter and tonic agent. Given in powder, or pill, or extract, with addition of a few drops of the oil, it is of great service in dyspepsia, atonic gout, and in intermittent fevers. The infusion may be made the vehicle for alkalies or acids.

The infusion when tepid is emetic, and may be given beneficially in dyspepsia, and at the commencement of catarrh (particularly influenza), and hooping-cough.

The decoction is an objectionable form, as it dissipates the oil. Even the infusion should be made with cold water. A most grateful aperient for weak dyspeptic patients is made by steeping senna leaves, chamomile flowers, and a very few cardamoms for ten hours in cold water, straining, and adding to the infusion any saline medicine required. The extract possesses valuable tonic properties, but in preparing it the volatile oil is dissipated, which deprives it of aroma. This may be restored to it by adding a few drops of the volatile oil. Extract of chamomile, with sulphate of quinine and the volatile oil, furnishes a combination of immense power in improving the appetite and aiding the digestion in convalescences from acute diseases, or after an attack of gout.

Infusion of chamomile, either warm or cold, furnishes an excellent application to weak eyes, or after exposure to the wind in travelling, especially by railroads. This used early will often ward off inflammation.

A'NTHEMIS (or ANACYCLUS) PYRETHRUM—*Medical Properties of.* Pellitory of Spain grows in the south of Europe, north of Africa, and in Syria, but the root of another variety, *Pyrethrum*, Willd. native of Germany, is also met with. The first is called the Roman or true Pellitory, the latter the German; this is necessary to be known, as the chemical analysis varies considerably. Gautier seems to have analysed the Roman, and found it to contain—

An acrid fixed oil or resin (Pyrethrin)	5
Volatile oil (a trace)	
Yellow extractive	14
Gum	11
Inulin	33
Muriate of lime (a trace)	
Woody matter	35
Loss	2
	100

It is devoid of smell, and though it does not at first excite any sensation in the mouth, it is followed by a pungent taste, and flow of saliva.

Its use is confined to local affections of the mouth, whether sub-inflammatory or paralytic. In rigidity of the muscles of the jaw, or rheumatic pains, from exposure to currents of air, chewing this is often of great service. An infusion may be held in the mouth, also, in toothache from cold. A tincture may be formed of it, which would be a useful agent in paralysis of the stomach, added to the infusion.

ANTHO'LOGY, a compound Greek word, used metaphorically, signifying "a Garland of Flowers," viz., of poetry, and consisting of short poems on amatory, convivial, moral, funereal, monumental, descriptive, dedicatory, satirical, and humorous subjects. Their characteristic merit consists in the just expression of a single thought with brevity and poetic beauty. The term *anthology* is peculiarly appropriated to a collection of Greek epigrams, taking the word not in the confined sense in which we now use it, for a pointed and witty conceit, but in the more enlarged and literal acceptation, of an *inscription*. The earliest and closest application of the term epigram was to certain short sentences inscribed on offerings in the temples. Inscriptions on buildings in general, on the statues of gods, heroes, living or dead men, next came under the denomination. They might be either in verse or prose. A moral precept, or the main bearing of a law, was embodied in this convenient form. Hence every little poem, presenting one distinct idea or insulated argument, gradually acquired the title of epigram. The largest portion of those collected in the Greek Anthology was written in honour of the dead, introducing their names and characters, or occupations; or as tributes to beauty, in gratitude for acceptance, or in complaint on account of rejection; some of them are panegyrics on living and illustrious virtue; others contain brief records of remarkable events; others again consist of observations on human life, for the most part in a dark style of colouring.

Meleager the Syrian, whose exact date seems difficult to fix, lived probably somewhat less than a century before the Christian era, and is generally understood to have first collected the scattered fragments of the Grecian inscriptive muse. Its interest mainly arises from its being a record of the intellectual vigour of Greece in its declining days, when her energy, whether in arms or in arts, had become less active, but had not entirely died away.

Philip of Thessalonica continued the work about the time of Tiberius. The additional compositions were less interesting, but still pleasing. In the sixth century Agathias collected the miscellaneous fragments of his time, and added his own contributions to the expiring muses of Greece. The bent of his own mind towards poetry seems to have been strong; in early youth he had produced a collection of amorous poems, entitled 'Daphniaca,' which would have done honour to better times. He had a coadjutor in his friend Paul the Silentiary (an officer in the court of Justinian, corresponding to the modern gentleman-usher), whose topics were desultory, and his style that of the courtier and the voluptuary. From the decay of manuscripts and the zeal of the clergy in the dark ages against all works of imagination or of gaiety, our present collection, although large, has lost many of its brightest and earliest ornaments; and it so happens, that it retains more pieces from the compilation of Agathias, than from that of his two predecessors conjointly.

In the 10th century, Constantinus Cephalas saved these manuscripts from oblivion by re-editing them. Maximus Planudes, a monk of the 14th century, was the last collector. The first printed edition of the 'Anthologia' was that of Lascaris, accompanied with some Greek verses by the editor, and a Latin epistle to Pietro de Medici. It bears the date of Florence, 1494. Claude de Saumaise, better known to the world by the Latin name of Salmasius, and to Englishmen as the antagonist of Milton, who lived in the 16th and the first half of the 17th centuries, detected the unfitness of Planudes for the duties of an editor, by the discovery, in 1606, of a MS. in the library of Heidelberg. During the 18th century, Suidas and the manuscripts in the public libraries of Europe were ransacked, and a valuable booty of epigrams, undiscovered or rejected by Planudes, enriched the 'Analecta' of Brunck and the 'Anthologia' of Jacobs. The former work, 'Analecta Veterum Poetarum Græcorum,' is contained in three volumes, octavo, Strasburg, 1772-6: the latter in thirteen volumes, octavo, Leipzig, 1794-1814. The edition of Jacobs is the latest, and best: but there is much matter strictly applicable to this purpose still left unedited. There are some inscriptions, for instance, in the Elgin collection of the British Museum, that ought to be added to any future edition.

A volume of translations, chiefly from the Greek 'Anthology,' was published in 1806 by Messrs. Bland and Merivale, with contributions from other gentlemen. Subsequent editions have been since published, in which the superfluities of the preceding ones are removed, and a number of additional specimens, many of them by younger translators, are introduced: and in this state the work may be recommended as presenting a very elegant and faithful specimen of the original Greek Anthology, and one which is not likely to be surpassed. (For a full account of the editions, &c., of the Anthology, see Schoell, 'Geschichte der Griech. Litt.' vol. iii.)

ANTHRACIN. [PARANAPHTHALIN.]

ANTHRANILIC ACID. [PHENYL; CARBAMIC ACID.]

ANTHROPO'GRAPHY, a term designed to express the object of one branch of physical geography.

The object of anthropography, which literally signifies *man-description*, is, to describe the actual geographical distribution of the human race; to classify it according to the varieties of physical character and language; to distinguish between nations or tribes which have the same general physical character and speak the same language, and nations or tribes which seem to belong to one stock, and have from circumstances adopted the language of another stock; to describe briefly the religious and domestic usages which constitute the basis of national character.

The term ethnography (nation-description) is sometimes used by German writers in the sense which we have given to anthropography; though, as far as we have observed, when so used, the word ethnography is rather more limited in its signification than that which we have assigned to anthropography. Some German writers use also the word *Völkerkunde* (people-knowledge) as an equivalent to ethnography. But ethnography has of late years been rather used to express an historical investigation into the origin and migrations and connection of various peoples. Taking it in this sense, ethnography is purely of an historical character, and may be considered as distinct from anthropography. A series of anthropographies, of different epochs, would form the true basis of ethnography.

ANTHROPOMORPHISM, a compound Greek word, literally signifying "the representation of human form:" but it is properly used to signify the "representation of divinity under a human form;" and the nations or sects who have followed this practice have been sometimes called Anthropomorphites. The Egyptians represented deities under human forms, as well as those of animals, and sometimes under a combination of the two. The ancient Persians, as Herodotus tells us (i. 131), adored the Supreme Being under no visible form of their own creation, but they worshipped on the tops of mountains, and sacrificed to the sun and moon, to earth, fire, water, and the winds. The Hebrews were forbidden (Exod. xx. 4, 5) to make any image or the representation of any animated being whatever.

The Greeks were essentially anthropomorphists, and could never separate the idea of superior powers from the representation of them under a human form: hence, in their mythology and in their arts, each deity had his distinguishing attributes and a characteristic human shape. Painters in modern times have, in Roman Catholic countries, represented both the First and Second Persons of the Trinity under a human form: in Protestant countries our Saviour is usually only so represented during his sojourn on earth, though individual painters have represented the risen and glorified Saviour.

Anthropomorphists is also the name of a sect of early Christians.

ANTHROPOPHAGI. [CANNIBALS.]

ANTIARIN ($C_{14}H_{20}O_{10}$), the poisonous principle of the *Upas antiar.* It forms small pearly crystals, soluble in 27 parts of boiling water, and also in alcohol and ether; it cannot be sublimed without decomposition. Introduced into a wound, it rapidly brings on vomiting, convulsions, and death. The gum resin from which it is extracted is used by the Javanese for poisoning their arrows.

According to Mulder, this gum-resin contains—

Vegetable albumen	16·14
Gum	12·34
Resin	20·93
Myricine	7·02
Antiarin	3·56
Sugar	6·31
Extractive matter	33·70
	100·00

ANTI-ATTRITION, is a preparation used to lessen friction in machinery, and also to prevent iron from rusting. It is made by grinding black lead with four times its weight of lard or tallow, and adding a little camphor to the mixture.

ANTICHRIST (Ἀντίχριστος) means, literally, the opponent of the anointed, or of the Messiah. The name of Antichrist was given by Jews and Christians to the great enemy of true religion, who shall, according to the Holy Scriptures, appear before the coming of the Messiah in glory.

The name of Antichrist occurs in the New Testament only in the first two epistles of St. John: thus, 1 Epist. ii. 18, 22, St. John says, "He is antichrist, that denieth the Father and the Son;" and in chap. iv. 3, "Every spirit that confesseth not that Jesus Christ is come in the flesh is not of God: and this is that spirit of antichrist, whereof ye have heard that it should come; and even now already is in the world." See also 2 Epist. 7. St. Paul calls Antichrist that *man of sin*, the son of perdition; who opposeth and exalteth himself above all that is called God, or that is worshipped; so that he sitteth in the temple of God, showing himself that he is God. That Wicked "whom the Lord shall consume with the spirit of his mouth, and shall destroy with the brightness of his coming:" "whose coming is after the working of Satan, with all power and signs and lying wonders."—2 Thess. ii. Emblematical descriptions of Antichrist occur in the twelfth and thirteenth chapters of the Revelations.

ANTIDICOMARIANITES (from two Greek words signifying *adversary*, and *Mary*), a sect of so-called heretics, whose peculiar belief was that Mary the mother of our Saviour did not continue a virgin after his birth, as the Roman Catholic Church asserts that she did to the end of her life, but bore other children to her husband Joseph. The founders or first preachers of Antidicomarianitism were Helvidius and Jovinian, two Roman theologians of the latter part of the 4th century, the latter of whom is also charged with various other heresies. The original accounts of Helvidius and Jovinian, and of their opinions, are to be found in the writings of Augustine, Jerome, and Epiphanius, who were their contemporaries.

ANTIDOTES, from two Greek words, signifying, *given against;* the means of counteracting the effects of poisons. The term *antidote* had formerly a much wider signification, and was applied to the remedies for diseases occurring from natural causes, as well as to the remedies for the derangements of the functions arising from the direct introduction into the system of a known and material poison. Doubtless every disease may be looked upon as springing from some poison; as fevers from an altered and unhealthy state of the atmosphere; or eruptive and contagious diseases from the vitiated fluids or breath of one individual communicated to another, as small-pox, and hooping-cough. This opinion is expressed by the employment of the term *virus*, or *poison*, to signify the immediate cause of such diseases; as when we speak of the small-pox virus, or the vaccine virus.

But as, in the present day, the word antidote is used only to signify the means of counteracting the effects of poisons, strictly so called, we shall confine our observations to what is properly comprehended under the term, when employed in this sense. While thus limiting its signification, it is equally necessary that we should limit the application of the word *poison*. It is, however, extremely difficult to define what a poison is. Foderé considers poisons to be "those substances known to be capable of rapidly altering or destroying some or all of the functions necessary to life." This must be understood to apply to their introduction (whether accidentally, intentionally on the part of the person suffering, or criminally on the part of others) into the body when in the usual state of health; for there are certain diseased conditions of the system, which seem to render it incapable of being injuriously affected by doses of medicines which at another time would speedily destroy life; and other states, such as when the body is under the influence of one poison, where another proves the most effectual remedy or antidote. This latter state is strikingly exemplified in the case of the bite of the *Coluber carinatus*, a species of snake common in the West Indies, during the state of stupor or insensibility occasioned by which, a large quantity of arsenic may be given, not only with safety, but with such advantage that the recovery of the patient may be considered as owing solely to it.

To acquire a correct idea of the different ways in which poisons operate in destroying life, we must be made aware that what we commonly regard as an *individual*, is made up of a number of distinct organs, which, though in some respects independent of each other, yet exert a reciprocal influence, the harmonious play of the whole being necessary to the continuous exercise or display of the principle of life, and that a cessation of the functions of any one of the more important organs necessitates the successive suspension of the rest. The most essential of these are consequently denominated the *vital functions*, viz., the circulation, respiration, and innervation. The circulation of red or *arterial* blood through the system, but especially through the nervous matter of the brain and spinal chord, is essential to the existence of the vital properties, and due performance of the functions of the different organs—which circulation is effected by the action of the *heart*,—while, to render the blood arterial, respiration is necessary, and this is effected by the *lungs*, assisted by a great number of muscles, the co-operation, or simultaneous action of which is occasioned by the influence of the *spinal chord*, directed or influenced by the *brain*. Now, certain poisons act either solely on one of these organs and functions, or upon two or three, but always in an ascertained order or uniform succession. Oxalic acid (or the acid of sugar, as it is popularly called), for example, in a small dose, acts first on the brain and spinal chord, but in a larger dose also affects the heart: in the former case, the respiration will be perceptibly interfered with, while the heart will go on acting for some time; in the latter case, both will cease at the same moment. Recovery, therefore, is much more probable in the first instance than in the second; for we can carry on *artificial* respiration till the brain and spinal chord have resumed the exercise of their functions; but if, as in the second instance, the heart also has ceased to act, recovery is impossible.

An arrangement of poisons according to their mode of action, that is, according to the order in which the vital functions are successively affected and destroyed by them, would be of great utility in regulating our treatment, teaching us when to be content with the employment of antidotes alone, and when to employ supplementary means,—as artificial respiration, blood-letting, &c. At present we can only make an approximation to such an arrangement.

Another point of consequence is the settlement of the question,—Do poisons act solely on the sentient extremities of the nerves of the part to which they are applied, and influence remote organs, only by sympathy, or are they absorbed into the circulating fluids, and by them carried to the organs, whose impaired or suspended functions show them to be markedly affected by them? Without entering into this dispute, it may be stated that some poisons act in the one way, some in the other way, and a few in both. Of these, the first set are the most formidable and the most speedy in their action, allowing little time for the employment of antidotes.

Some poisons act, but with different degrees of violence and speed, whatever part of the body they are applied to; others, again, only when received into the stomach or intestines; while some, such as the poison of the viper, are quite powerless when swallowed. Of all parts of the body, the brain and nervous substance are the least susceptible of the action of poisons, when applied directly to them, though acted upon by so many poisons when applied elsewhere.

With respect to the local operation of poisons, that is, their direct action on the part to which they are applied, some decompose chemically, or alter the structure of (corrode) the part which they touch, and hence they are called *corrosive* poisons; such are the mineral acids, of which sulphuric, or oil of vitriol may serve as an example. Besides this local effect, many of the corrosive poisons act speedily upon remote organs, the impaired function of which may become a source of greater danger than the destruction of the part first attacked.

Other poisons, without immediately altering the structure of the part, irritate it so that inflammation ensues, by which it is altered, and the general system affected, as it would be by inflammation of the same part arising from any other cause—even when the poisonous substance does not produce any immediate or powerful effect upon a remote organ—which is not often the case, as most of them influence some of the vital functions, and thus prove fatal. These are termed *irritant* poisons, such as arsenic; but they are frequently also termed corrosives, though inaccurately.

Lastly, there are poisons which neither corrode nor irritate the part, but cause a peculiar impression upon the sentient extremities of the nerves, which is conveyed along these to some remote organ or organs, the function of which they impair or suspend. Many of these should be termed sedatives, in the strictest sense of the word [SEDATIVES]; others are narcotics; and those which produce some degree of local irritation are termed narcotico-acrids. But often one and the same article, according to the dose and mode of administration, acts in all the three ways; tobacco, for example.

The selection of appropriate means to counteract the effects of poisons must be determined by a knowledge of the manner in which each particular poison acts; but as we cannot enumerate or specify these here, we shall give only general rules to this effect. These may be reduced to three, namely, 1, to remove the poisonous substance; 2, to prevent or limit its local effects; 3, to obviate its effects on remote organs, supporting their action by appropriate measures, till the injurious impression has subsided. The first of these is to be accomplished mostly by mechanical means. If the poison has been applied to any external part, as by the bite of a viper or rattle-snake, a cupping-glass, or what will answer as well, a wine-glass, tumbler, or cup of any kind, from which a part of the air has been expelled, by holding within it a lighted candle for a second of time, should be immediately applied. If the poison has been taken into the stomach, and is not of a kind to arrest instantly the action of the heart, its removal is to be attempted by the stomach-pump, or by exciting vomiting. The stomach-pump cannot well be used without introducing into the stomach a considerable quantity of water, which, by diluting the poison, lessens its violence in all cases, except that of oxalic acid. The stomach-pump is also to be preferred in the case of narcotic poisons, as the insensibility which they occasion prevents the stomach from being affected by emetics. But should a stomach-pump not be at hand, nor any one be present skilled in the use of it, we must attempt to produce vomiting by every means in our power. For this purpose, a table-spoonful of flour of mustard, which is mostly to be found in every house, may be put into a tumbler of warm water, and given to the patient; or a scruple of sulphate of zinc (white vitriol) dissolved in a pint of distilled water; or ten grains of sulphate of copper dissolved in half a pint of any distilled water, as cinnamon, may be drunk by the patient, and the disposition to vomit encouraged by tickling the throat with a feather, and pressing on the pit of the stomach. Neither ipecacuanha nor tartar emetic should be given, as their action is always preceded by much nausea, during which the absorption of the poison is often facilitated.

Where the poison is of a corrosive or irritant nature, instead of losing time in seeking the means of causing vomiting, it is in general advisable to adopt the second rule, and attempt to prevent or limit its local, and thereby its remote, effects. To accomplish this, we must ascertain what the poisonous substance was, from which the patient is suffering, and must also know how it acts, as upon this depends the success of our treatment. The objects we must have in view are either to dilute, and so weaken it; to supply from an external source the particular principle, which the poison would abstract from the coats of the stomach; or by adding something to it, so change its nature as to render it comparatively or altogether harmless, which last will always be effected, if we can succeed in forming an insoluble compound. The first may be done by giving plenty of warm water; and when we know the particular poison, if the warm water can be made the vehicle of an antidote, the second or third object will also be insured. Suppose sulphuric acid (oil of vitriol) has been swallowed, add to the water chalk, magnesia, or soap: the chalk will make, with the acid, sulphate of lime, which being insoluble, will do no harm, while with the magnesia the acid will form sulphate of magnesia (Epsom salts), and with the soap sulphate of potash, both of which are purgative salts, and will, by their action on the bowels, assist in lessening the inflammation caused by the poison before it was decomposed. So when sugar of lead (acetate of lead) is swallowed, by giving Epsom salts we form an insoluble sulphate of lead, which will be discharged by the bowels operated upon by the magnesia, which has been freed from the sulphuric acid. Corrosive sublimate (bi-chloride) of mercury abstracts from the coats of the stomach the albumen which they contain, by which it is converted into protochloride, or calomel; now, if by giving white of egg, which is pure albumen, we supply it with the principle which it would otherwise obtain from the coats of the stomach, we shall preserve these entire.

Such means, then, are antidotes, properly speaking; for the means by which the secondary or remote effects are to be combated, deserve rather to be termed counter-poisons. The counter-poisons are of no small value in cases of poisoning by the corrosive and irritant, while they are of the utmost importance in the treatment of the sedative and narcotic poisons. To administer these appropriately, we must know which of the vital organs the poison most speedily affects. When it affects the heart, the symptoms greatly resemble syncope (or fainting), and as such poisons are the most dangerous, agents which act as rapidly as the poisons are alone to be trusted to: such agents are to be found among the diffusible stimuli, ammonia, or its carbonate, that is, smelling salts, applied to the nostrils, or dissolved in water and taken into the stomach, warm brandy and water, &c. Where it chiefly affects the spinal marrow, there occur spasms and difficulty of breathing; and when the brain, there is partial or complete insensibility (coma), often with, at first, full pulse, flushed face, and laborious breathing, resembling apoplexy. In such a state of affairs, artificial respiration, and afterwards bleeding, with the subsequent administration of coffee or vinegar, greatly contribute to save the patient.
